For example, the IOU contract resides on the `iou` sync domain because it has been created by a command that was submitted to the `iou` sync domain. Similarly, the paint offer resides on the `paint` sync domain. In the current version of Canton, the execution of a transaction can only use contracts that reside on a single sync domain. Therefore, before the painter can accept the offer and thereby become the owner of the IOU contract, both contracts must be brought to a common sync domain.

In this example, the house owner and the painter are hosted on participants that are connected to both sync domains, whereas the Bank is only connected to the `iou` sync domain. The IOU contract cannot be moved to the `paint` sync domain because all stakeholders of a contract must be connected to the contract's sync domain of residence. Conversely, the paint offer can be transferred to the `iou` sync domain, so that the painter can accept the offer on the `iou` sync domain.

Stakeholders can change the residence sync domain of a contract using the `transfer.execute` command. In the example, the painter transfers the paint offer from the `paint` sync domain to the `iou` sync domain.

```
// Wait until the painter sees the paint offer in the active contract store
participant3.ledger_api.acs.await_active_contract(Painter, paintOffer.id.toLf)

// Painter transfers the paint offer to the IOU domain
participant3.transfer.execute(
  Painter,           // Initiator of the transfer
  paintOffer.id.toLf, // Contract to be transferred
  paintAlias,        // Source domain
  iouAlias,           // Target domain
)
```

The transfer of a contract effectively changes the residence sync domain of the contract, in other words, the consensus among the stakeholders on which sync domain should be used to sequence actions on a contract. The contract itself is still stored only on the involved participants.

23.6.1.5 Atomic acceptance

The paint offer and the IOU contract both reside on the `iou` sync domain now. Accordingly, the painter can complete the workflow by accepting the offer.

```
// Painter accepts the paint offer on the IOU domain
val acceptCmd = paintOffer.id.exerciseAcceptByPainter().commands.asScala.toSeq
val acceptTx = participant3.ledger_api.javaapi.commands.submit_flat(Seq(Painter), □
  ← acceptCmd)
val Seq(painterIou) = decodeAllCreated(Iou.COMPANION)(acceptTx)
val Seq(paintHouse) = decodeAllCreated(PaintHouse.COMPANION)(acceptTx)
```

This transaction executes on the `iou` sync domain because the input contracts (the paint offer and the IOU) reside there. It atomically creates two contracts on the `iou` sync domain: the painter's new IOU and the agreement to paint the house. The unhappy scenarios needing out-of-band resolution are avoided.

23.6.1.6 Completing the workflow

Finally, the paint agreement can be transferred back to the paint sync domain, where it belongs.

```
// Wait until the house owner sees the PaintHouse agreement
participant2.ledger_api.acs.await_active_contract(HouseOwner, paintHouse.id.toLf)

// The house owner moves the PaintHouse agreement back to the Paint domain
participant2.transfer.execute(
  HouseOwner,
  paintHouse.id.toLf,
  iouAlias,
  paintAlias
)
```

Note that the painter's IOU remains on the iou sync domain. The painter can therefore call the IOU and cash it out.

```
// Painter converts the Iou into cash
participant3.ledger_api.javaapi.commands.submit_flat(
  Seq(Painter),
  painterIou.id.exerciseCall().commands.asScala.toSeq,
  iou.name
)
```

23.6.1.7 Performing transfers automatically

Canton also supports automatic transfers for commands performing transactions that use contracts residing on several sync domains. When such a command is submitted, Canton can automatically infer a common sync domain that the used contracts can be transferred to. Once all the used contracts have been transferred into the common sync domain the transaction is performed on this single sync domain. However, this simply performs the required transfers followed by the transaction processing as distinct non-atomic steps.

We can therefore run the above script without specifying any transfers at all, and relying on the automatic transfers. Simply delete all the transfer commands from the example above and the example will still run successfully. A modified version of the above example that uses automatic transfers instead of manual transfers is given below.

The setup code and contract creation is unchanged:

```
// Bank creates IOU for the house owner
val createIouCmd = new Iou(
  Bank.toProtoPrimitive,
  HouseOwner.toProtoPrimitive,
  new Amount(100.0.toBigDecimal, "USD"),
  List.empty.asJava
).create.commands.asScala.toSeq
val Seq(iouContractUnshared) = decodeAllCreated(Iou.COMPANION) (
  participant1.ledger_api.javaapi.commands.submit_flat(Seq(Bank), createIouCmd))

// Wait until the house owner sees the IOU in the active contract store
participant2.ledger_api.acs.await_active_contract(HouseOwner, iouContractUnshared.
↳id.toLf)
```

(continues on next page)

(continued from previous page)

```
// The house owner adds the Painter as an observer on the IOU
val showIouCmd = iouContractUnshared.id.exerciseShare(Painter.toProtoPrimitive).
  ↳ commands.asScala.toSeq
val Seq(iouContract) = decodeAllCreated(Iou.COMPANION) (participant2.ledger_api.
  ↳ javaapi.commands.submit_flat(Seq(HouseOwner), showIouCmd))

// The house owner creates a paint offer using participant 2 and the Paint domain
val paintOfferCmd = new OfferToPaintHouseByOwner (
  HouseOwner.toProtoPrimitive,
  Painter.toProtoPrimitive,
  Bank.toProtoPrimitive,
  iouContract.id
).create.commands.asScala.toSeq
val Seq(paintOffer) = decodeAllCreated(OfferToPaintHouseByOwner.COMPANION) (
  participant2.ledger_api.javaapi.commands.submit_flat(Seq(HouseOwner),
  ↳ paintOfferCmd, workflowId = paint.name))
```

In the following section, the painter accepts the paint offer. The transaction that accepts the paint offer uses two contracts: the paint offer contract, and the IOU contract. These contracts were created on two different sync domains in the previous step: the paint offer contract was created on the paint sync domain, and the IOU contract was created on the IOU sync domain. The paint offer contract must be transferred to the IOU sync domain for the accepting transaction to be successfully applied, as was done manually in the example above. It would not be possible to instead transfer the IOU contract to the paint sync domain because the stakeholder Bank on the IOU contract is not represented on the paint sync domain.

When using automatic-transfer transactions, Canton infers a suitable sync domain for the transaction and transfers all used contracts to this sync domain before applying the transaction. In this case, the only suitable sync domain for the painter to accept the paint offer is the IOU sync domain. This is how the painter can accept the paint offer below without any explicit transfers being performed.

```
// Wait until the painter sees the paint offer in the active contract store
participant3.ledger_api.acs.await_active_contract(Painter, paintOffer.id.toLf)

// Painter accepts the paint offer on the IOU domain
val acceptCmd = paintOffer.id.exerciseAcceptByPainter().commands.asScala.toSeq
val acceptTx = participant3.ledger_api.javaapi.commands.submit_flat(Seq(Painter),
  ↳ acceptCmd)
val Seq(painterIou) = decodeAllCreated(Iou.COMPANION) (acceptTx)
val Seq(paintHouse) = decodeAllCreated(PaintHouse.COMPANION) (acceptTx)
```

The painter can then cash in the IOU. This happens exactly as before, since the IOU contract never leaves the IOU sync domain.

```
// Painter converts the Iou into cash
participant3.ledger_api.javaapi.commands.submit_flat(
  Seq(Painter),
  painterIou.id.exerciseCall().commands.asScala.toSeq,
  iou.name
)
```

Note that towards the end of the previous example with explicit transfers, the paint offer contract was transferred back to the paint sync domain. This doesn't happen in the automatic transfer version:

the paint offer is not transferred out of the IOU sync domain as part of the script shown. However, the paint offer contract will be automatically transferred back to the paint sync domain once it is used in a transaction that must happen on the paint sync domain.

Details of the automatic-transfer transactions

In the previous section, the automatic-transfer transactions were explained using an example. The details are presented here.

The automatic-transfer transactions enable submission of a transaction using contracts on multiple sync domains, by transferring contracts into a chosen target sync domain and then performing the transaction. However, using an automatic-transfer transaction does not provide any atomicity guarantees beyond using several primitive transfer-in and transfer-out operations (these operations make up the `transfer.execute` command, and are explained in the next section).

The sync domain for a transaction is chosen using the following criteria:

- Minimise the number of transfers needed.
- Break ties by choosing sync domains with higher priority first.
- Break ties by choosing sync domains with alphabetically smaller sync domain IDs first.

As for ordinary transactions, you may force the choice of sync domain for an automatic-transfer transaction by setting the workflow ID to name of the sync domain.

The automatic-transfer transactions are only enabled when all of the following are true:

- The local Canton console enables preview commands (see the [configuration](#) section).
- The submitting participant is connected to all sync domains that contracts used by the transaction live on.
- All contracts used by the transaction must have at least one stakeholder that is also a transaction submitter.

23.6.1.8 Takeaways

A contract resides on a sync domain. This means that the current agreement of the stakeholders is to communicate and sequence all access and changes to a given contract on a particular sync domain. The contract itself is only stored at the stakeholder participants. Stakeholders can move contracts from one sync domain to another using `transfer.execute`. All stakeholders must be connected to the source and the target sync domain. You can submit transactions using contracts that reside on several sync domains. Automatic transfers will pick a suitable sync domain, and perform the transfers into it before performing the transaction.

23.6.2 Part 2: Composing existing workflows

This part shows how existing workflows can be composed even if they work on separate sync domains. The running example is a variation of the paint example from the first part with a more complicated topology. We therefore assume that you have gone through [the first part](#) of this tutorial. Technically, this tutorial runs through the same steps as the first part, but more details are exposed. The console commands assume that you start with a fresh Canton console.

23.6.2.1 Existing workflows

Consider a situation where the two sync domains `iou` and `paint` have evolved separately:

The `iou` sync domain for managing IOUs,
The `paint` sync domain for managing paint agreements.

Accordingly, there are separate applications for managing IOUs (issuing, changing ownership, calling) and paint agreements, and the house owner and the painter have connected their applications to different participants. The situation is illustrated in the following picture.

To enter into a paint agreement in this setting, the house owner and the painter need to perform the following steps:

1. The house owner creates a paint offer through Participant 2 on the `paint` sync domain.
2. The painter accepts the paint offer through Participant 3 on the `paint` sync domain. As a consequence, a paint agreement is created.
3. The painter sets a reminder that he needs to receive an IOU from the house owner on the `iou` sync domain.
4. When the house owner observes a new paint agreement through Participant 2 on the `paint` sync domain, she changes the IOU ownership to the painter through Participant 5 on the `iou` sync domain.
5. The painter observes a new IOU through Participant 4 on the `iou` sync domain and therefore removes the reminder.

Overall, a non-trivial amount of out-of-band coordination is required to keep the `paint` ledger consistent with the `iou` ledger. If this coordination breaks down, the [unhappy scenarios from the first part](#) can happen.

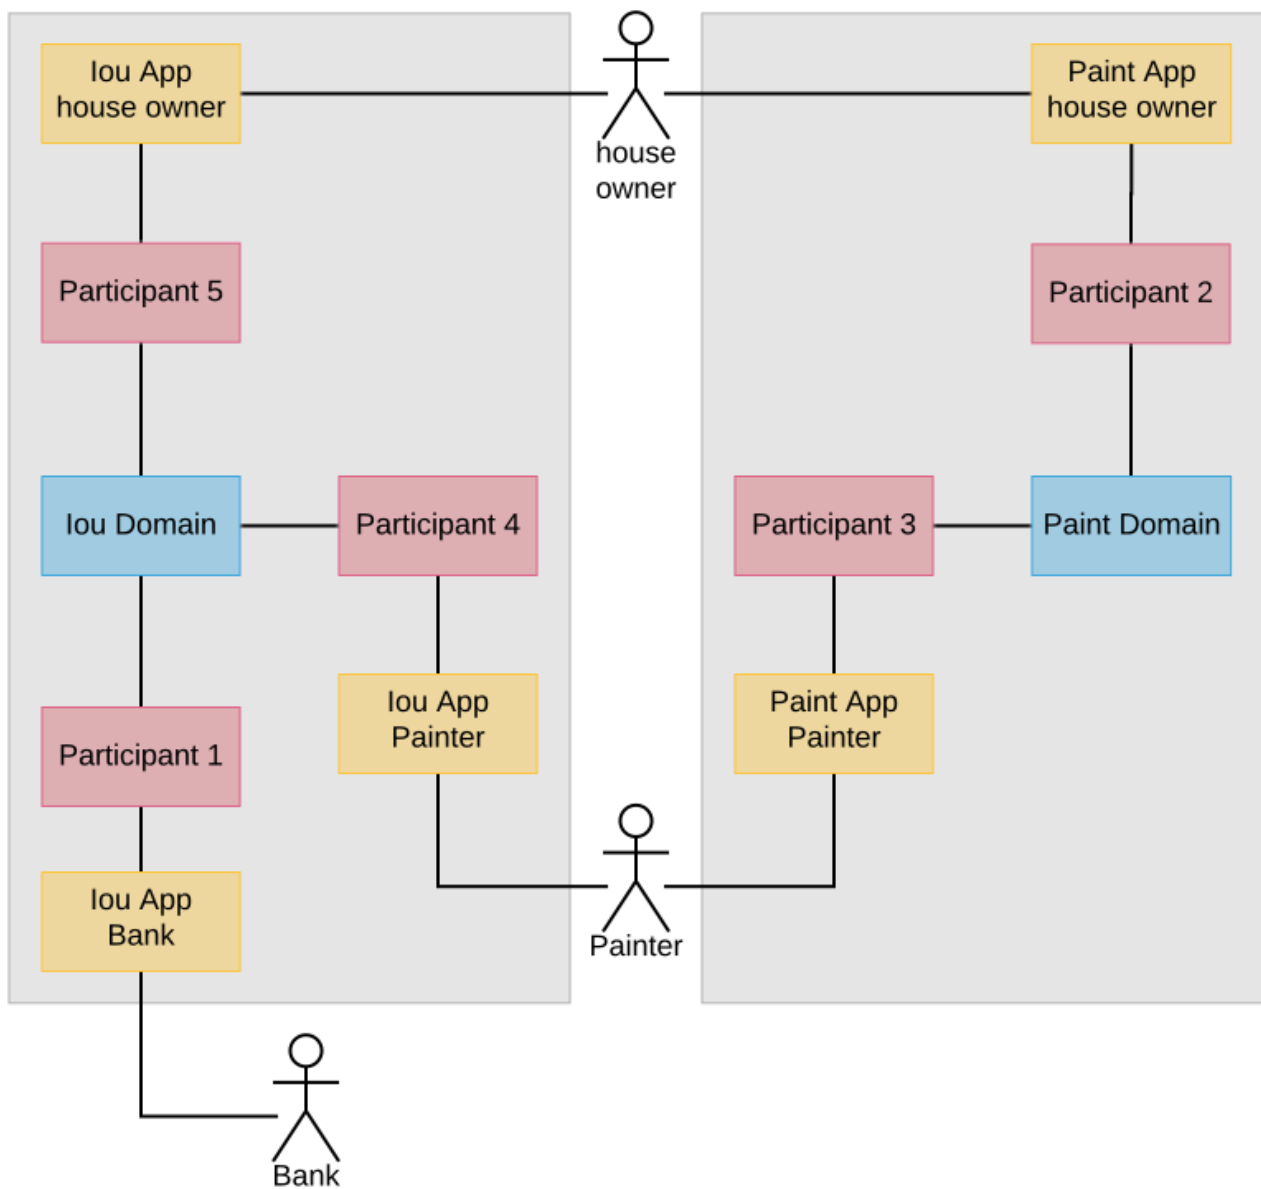

23.6.2.2 Required changes

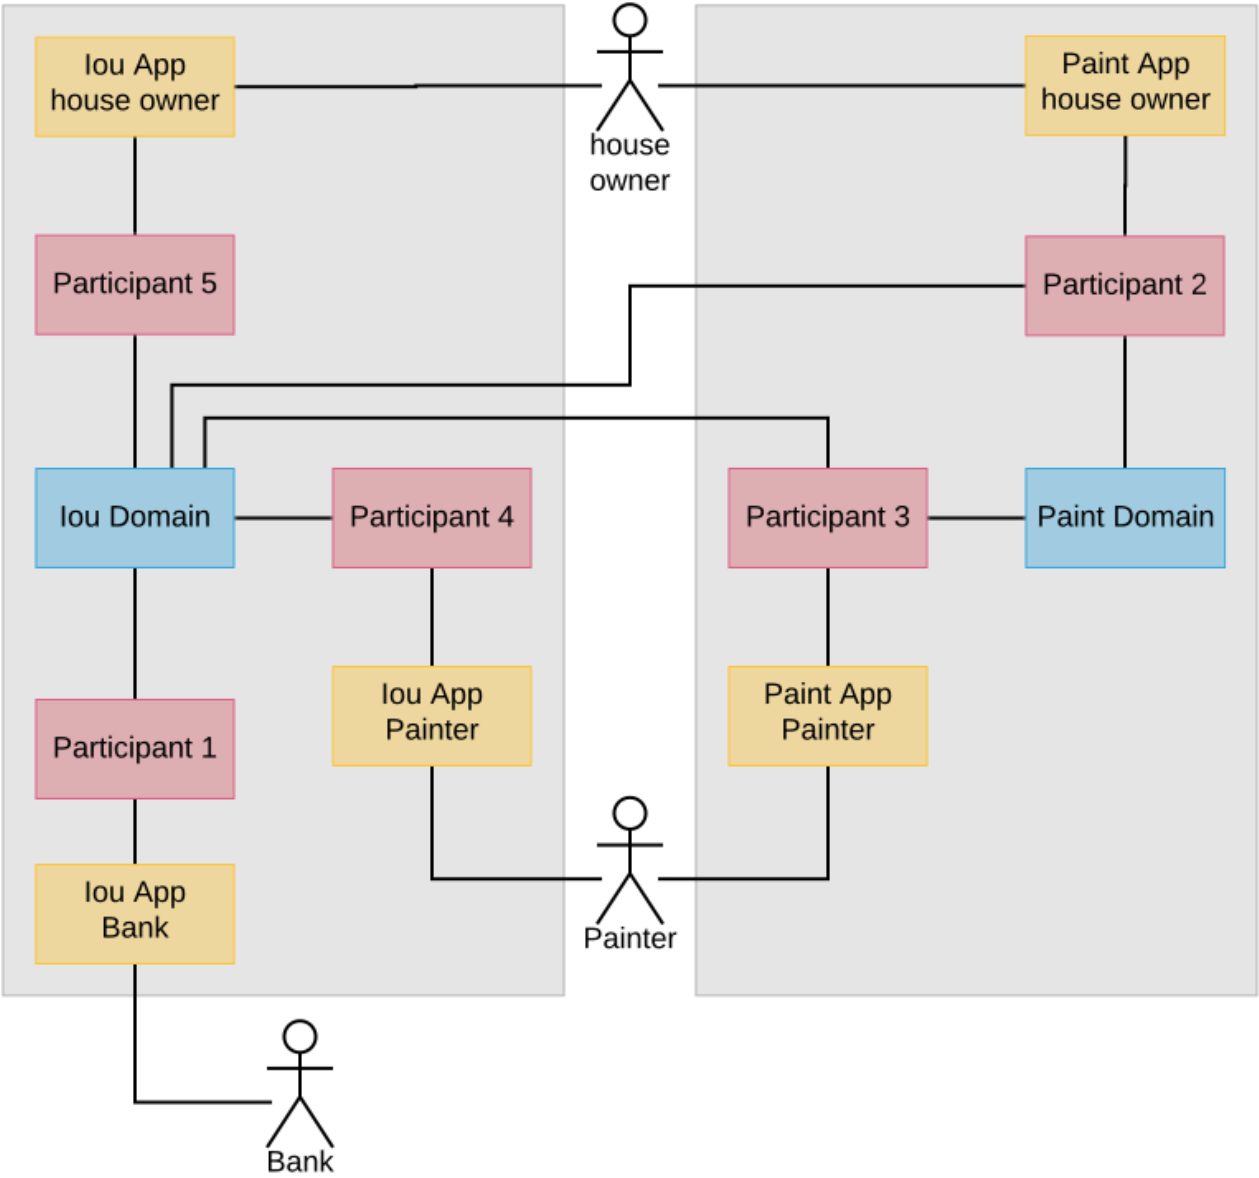

We now show how the house owner and the painter can avoid the need for out-of-band coordination when entering into paint agreements. The goal is to reuse the existing infrastructure for managing IOUs and paint agreements as much as possible. The following changes are needed:

1. The house owner and the painter connect their participants for paint agreements to the `iou` sync domain:
The [Canton configuration](#) is accordingly extended with the two participants 4 and 5. (The connections themselves are set up in the [next section](#).)

```
canton {  
  participants {  
    participant4 {  
      ledger-api.port = 13041  
      admin-api.port = 13042
```

(continues on next page)

(continued from previous page)

```

        storage.type = memory
        init.parameters.unique-contract-keys = false
    }

    participant5 {
        ledger-api.port = 13051
        admin-api.port = 13052
        storage.type = memory
        init.parameters.unique-contract-keys = false
    }
}

```

2. They replace their Daml model for paint offers such that the house owner must specify an IOU in the offer and its accept choice makes the painter the new owner of the IOU.
3. They create a new application for the [paint offer-accept workflow](#).

The Daml models for IOUs and paint agreements themselves remain unchanged, and so do the applications that deal with them.

23.6.2.3 Preparation using the existing workflows

We extend the topology from the first part as described. The commands are explained in detail in Canton's [identity management manual](#).

```

// update parameters
iou.service.update_dynamic_domain_parameters(
  _.update(transferExclusivityTimeout = Duration.Zero)
) // disable automatic transfer-in

paint.service.update_dynamic_domain_parameters(
  _.update(transferExclusivityTimeout = 2.seconds)
)

// connect participants to the domain
participant1.domains.connect_local(iou)
participant2.domains.connect_local(iou)
participant3.domains.connect_local(iou)
participant2.domains.connect_local(paint)
participant3.domains.connect_local(paint)
participant4.domains.connect_local(iou)
participant5.domains.connect_local(iou)

val iouAlias = iou.name
val paintAlias = paint.name

// create the parties
val Bank = participant1.parties.enable("Bank")
val HouseOwner = participant2.parties.enable("House Owner")
val Painter = participant3.parties.enable("Painter", waitForDomain = DomainChoice.
↳ All)

// enable the house owner on participant 5 and the painter on participant 4
// as explained in the identity management documentation at
// https://docs.daml.com/canton/usermanual/identity_management.html#party-on-two-
↳ nodes

```

(continues on next page)

(continued from previous page)

```

import com.digitalasset.canton.console.ParticipantReference
def authorizePartyParticipant(partyId: PartyId, createdAt: ParticipantReference,
  ↳ to: ParticipantReference): Unit = {
  val createdAtP = createdAt.id
  val toP = to.id
  createdAt.topology.party_to_participant_mappings.authorize(TopologyChangeOp.Add,
  ↳ partyId, toP, RequestSide.From)
  to.topology.party_to_participant_mappings.authorize(TopologyChangeOp.Add,
  ↳ partyId, toP, RequestSide.To)
}
authorizePartyParticipant(HouseOwner, participant2, participant5)
authorizePartyParticipant(Painter, participant3, participant4)

// Wait until the party enabling has taken effect and has been observed at the
  ↳ participants
val partyAssignment = Set(HouseOwner -> participant2, HouseOwner -> participant5,
  ↳ Painter -> participant3, Painter -> participant4)
participant2.parties.await_topology_observed(partyAssignment)
participant3.parties.await_topology_observed(partyAssignment)

// upload the Daml model to all participants
val darPath = Option(System.getProperty("canton-examples.dar-path")).getOrElse(
  ↳ "dars/CantonExamples.dar")
participants.all.dars.upload(darPath)

```

As before, the Bank creates an IOU and the house owner shares it with the painter on the `iou` sync domain, using their existing applications for IOUs.

```

import com.digitalasset.canton.BigDecimalImplicits._
import com.digitalasset.canton.examples.java.iou.{Amount, Iou}
import com.digitalasset.canton.examples.java.paint.{OfferToPaintHouseByOwner,
  ↳ PaintHouse}
import com.digitalasset.canton.participant.ledger.api.client.JavaDecodeUtil._
  ↳ decodeAllCreated
import com.digitalasset.canton.protocol.ContractIdSyntax._

import scala.jdk.CollectionConverters._

val createIouCmd = new Iou(
  Bank.toProtoPrimitive,
  HouseOwner.toProtoPrimitive,
  new Amount(100.0.toBigDecimal, "USD"),
  List.empty.asJava
).create.commands.asScala.toSeq
val Seq(iouContractUnshared) = decodeAllCreated(Iou.COMPANION) (
  participant1.ledger_api.javaapi.commands.submit_flat(Seq(Bank), createIouCmd))

// Wait until the house owner sees the IOU in the active contract store
participant2.ledger_api.acs.await_active_contract(HouseOwner, iouContractUnshared.
  ↳ id.toLf)

// The house owner adds the Painter as an observer on the IOU
val shareIouCmd = iouContractUnshared.id.exerciseShare(Painter.toProtoPrimitive).
  ↳ commands.asScala.toSeq
val Seq(iouContract) = decodeAllCreated(Iou.COMPANION) (participant2.ledger_api.
  ↳ javaapi.commands.submit_flat(Seq(HouseOwner), shareIouCmd))

```

23.6.2.4 The paint offer-accept workflow

The new paint offer-accept workflow happens in four steps:

1. Create the offer on the `paint` sync domain.
2. Transfer the contract to the `iou` sync domain.
3. Accept the offer.
4. Transfer the paint agreement to the `paint` sync domain.

Making the offer

The house owner creates a paint offer on the `paint` sync domain.

```
// The house owner creates a paint offer using participant 2 and the Paint domain
val paintOfferCmd = new OfferToPaintHouseByOwner (
  HouseOwner.toProtoPrimitive,
  Painter.toProtoPrimitive,
  Bank.toProtoPrimitive,
  iouContract.id
).create.commands.asScala.toSeq
val Seq(paintOffer) = decodeAllCreated(OfferToPaintHouseByOwner.COMPANION) (
  participant2.ledger_api.javaapi.commands.submit_flat(Seq(HouseOwner),
  ↪ paintOfferCmd, workflowId = paint.name))
```

Transfers are not atomic

In the first part, we have used `transfer.execute` to move the offer to the `iou` sync domain. Now, we look a bit behind the scenes. A contract transfer happens in two atomic steps: transfer-out and transfer-in. `transfer.execute` is merely a shorthand for the two steps. In particular, `transfer.execute` is not an atomic operation like other ledger commands.

During a transfer-out, the contract is deactivated on the source sync domain, in this case the `paint` sync domain. Any stakeholder whose participant is connected to the source sync domain and the target sync domain can initiate a transfer-out. The `transfer.out` command returns a transfer ID.

```
// Wait until the painter sees the paint offer in the active contract store
participant3.ledger_api.acs.await_active_contract(Painter, paintOffer.id.toLf)

// Painter transfers the paint offer to the IOU domain
val paintOfferTransferId = participant3.transfer.out(
  Painter, // Initiator of the transfer
  paintOffer.id.toLf, // Contract to be transferred
  paintAlias, // Source domain
  iouAlias // Target domain
)
```

The `transfer.in` command consumes the transfer ID and activates the contract on the target synchronization.

```
participant3.transfer.in(Painter, paintOfferTransferId, iouAlias)
```

Between the transfer-out and the transfer-in, the contract does not reside on any sync domain and cannot be used by commands. We say that the contract is in transit.

Accepting the paint offer

The painter accepts the offer, as before.

```
// Wait until the Painter sees the IOU contract on participant 3.
participant3.ledger_api.acs.await_active_contract(Painter, iouContract.id.toLf)

// Painter accepts the paint offer on the Iou domain
val acceptCmd = paintOffer.id.exerciseAcceptByPainter().commands.asScala.toSeq
val acceptTx = participant3.ledger_api.javaapi.commands.submit_flat(Seq(Painter), □
  ↳ acceptCmd)
val Seq(painterIou) = decodeAllCreated(Iou.COMPANION)(acceptTx)
val Seq(paintHouse) = decodeAllCreated(PaintHouse.COMPANION)(acceptTx)
```

Automatic transfer-in

Finally, the paint agreement is transferred back to the paint sync domain such that the existing infrastructure around paint agreements can work unchanged.

```
// Wait until the house owner sees the PaintHouse agreement
participant2.ledger_api.acs.await_active_contract(HouseOwner, paintHouse.id.toLf)

val paintHouseId = paintHouse.id
// The house owner moves the PaintHouse agreement back to the Paint domain
participant2.transfer.out(
  HouseOwner,
  paintHouseId.toLf,
  iouAlias,
  paintAlias
)
// After the exclusivity period, which is set to 2 seconds,
// the contract is automatically transferred into the target domain
utils.retry_until_true(10.seconds) {
  // in the absence of other activity, force the participants to update their
  ↳ view of the latest domain time
  participant2.testing.fetch_domain_times()
  participant3.testing.fetch_domain_times()

  participant3.testing.acs_search(paint.name, filterId=paintHouseId.contractId).
  ↳ nonEmpty &&
    participant2.testing.acs_search(paint.name, filterId=paintHouseId.
  ↳ contractId).nonEmpty
}
```

Here, there is only a `transfer.out` command but no `transfer.in` command. This is because the participants of contract stakeholders automatically try to transfer-in the contract to the target sync domain so that the contract becomes usable again. The sync domain parameter `transfer-exclusivity-timeout` on the target sync domain specifies how long they wait before they attempt to do so. Before the timeout, only the initiator of the transfer is allowed to transfer-in the contract. This reduces contention for contracts with many stakeholders, as the initiator normally completes the transfer before all other stakeholders simultaneously attempt to transfer-in the contract. On the paint sync domain, this timeout is set to two seconds in the [configuration](#) file. Therefore, the `utils.retry_until_true` normally succeeds within the allotted ten seconds.

Setting the `transfer-exclusivity-timeout` to 0 as on the `iou` sync domain disables automatic transfer-in. This is why the above transfer of the paint offer had to be completed manually. Manual completion is also needed if the automatic transfer-in fails, e.g., due to timeouts on the target sync domain. Automatic transfer-in therefore is a safety net that reduces the risk that the contract gets stuck in transit.

23.6.2.5 Continuing the existing workflows

The painter now owns an IOU on the `iou` sync domain and the entered paint agreement resides on the `paint` sync domain. Accordingly, the existing workflows for IOUs and paint agreements can be used unchanged. For example, the painter can call the IOU.

```
// Painter converts the Iou into cash
participant4.ledger_api.javaapi.commands.submit_flat(
  Seq(Painter),
  painterIou.id.exerciseCall().commands.asScala.toSeq,
  iou.name
)
```

23.6.2.6 Takeaways

Contract transfers take two atomic steps: transfer-out and transfer-in. While the contract is being transferred, the contract does not reside on any sync domain.

Transfer-in happens under normal circumstances automatically after the `transfer-exclusivity-timeout` configured on the target sync domain. A timeout of 0 disables automatic transfer-in. If the automatic transfer-in does not complete, the contract can be transferred in manually.

23.7 Versioning

23.7.1 Canton release version

The Canton release version (release version for short) is the primary version assigned to a [Canton release](#). It is semantically versioned, i.e., breaking changes to a public API will always lead to a major version increase of the release version. The public APIs encompassed by the release version are the following:

- Ledger API server (for participants)
- Error code format (machine-readable parts, see also [the error code documentation](#))
- Canton configuration file format
- Command line arguments
- Internal storage (data continuity between non-major upgrades)
- Canton protocol version

As a result, Canton components are always safely upgradeable with respect to these APIs. In particular, the inclusion of the Canton protocol version as a Public API guarantees that any two Canton components of the same release version can interact with each other and can be independently upgraded within a major version without any loss of interoperability (see also [the documentation on the Canton protocol version](#)).

23.7.2 For application developers and operators

Applications using Canton have the following guarantees:

- Participants can be upgraded independently of each other and of applications and sync domains within a major release version.

- Sync domain drivers can be upgraded independently of applications and connected participants within a major release version.

- Major versions of anything are supported for a minimum of 12 months from the release of the next major release version.

As a result, applications written today can keep running unchanged for a minimum of 12 months while upgrading participants and sync domains within a major release version. See also the [versioning](#) as well as [portability, compatibility and support duration guarantees](#) that hold for any Daml application.

23.7.3 For Canton participant and synchronization domain operators

In addition to the Canton release version, the Canton protocol version is the most important version for participant and sync domain operators. It used to have 3 digits, but starting protocol version 4 it's represented by one digit.

23.7.3.1 Canton protocol version

The Canton protocol determines how different Canton components interact with each other. We version it using the Canton protocol version (protocol version for short) and conceptually, two Canton components can interact (are interoperable) if they support the same protocol version. For example, a participant can connect to a sync domain if it supports the protocol version that is spoken on the sync domain, and a mediator can become the mediator for a sync domain, if it supports the protocol version required by the sync domain. If two Canton components have the same major release version, they also share at least one protocol version and can thus interact with each other.

A Canton component advertises the protocol versions it supports and always supports all previous protocol versions of the same major release line. That is, a participant or driver supporting a certain protocol version can transact with all other participants or drivers supporting a lower or equal protocol version but may not be able to transact with participants or drivers supporting a higher Canton protocol if they are configured to use a more recent version of the protocol. For example, a release of a participant supporting protocol version 3 will be able to connect to all sync domains configured to use protocol version ≤ 3 . It won't be able to connect to a sync domain configured to use protocol version > 3 . As a result, minor and patch version upgrades of Canton components can be done independently without any loss of interoperability.

To see the protocol versions a Canton component supports (e.g., 2 and 3), run

```
canton --version
```

(where `canton` is an alias for the path pointing to the Canton release binary `bin/canton`).

The list of supported protocol versions for each minor version is the following:

(*) The protocol versions marked with * are the beta protocol version. To use a beta protocol version, follow the [documentation](#).

Release	Protocol versions
2.0	2
2.1	2
2.2	2
2.3	2, 3
2.4	2, 3
2.5	2, 3, 4
2.6	3, 4
2.7	3, 4, 5
2.8	3, 4, 5
2.9	5
2.10	5, 7

23.7.3.2 Features and protocol versions

Some Canton features are only available on sync domains running specific protocol versions. The following table indicates the protocol versions required to use some features.

Protocol version	Feature
4 and above	Interfaces

23.7.3.3 Configuring the protocol version

A Canton driver or sync domain operator is [able to configure](#) the protocol version spoken on the sync domain (e.g. 3). If the sync domain operator sets the protocol version spoken on a sync domain too high, they may exclude participants that do not support this protocol version yet.

For example, if the sync domain operator sets the protocol version on a sync domain to 3, participants that only support protocol version 2 aren't able to connect to the sync domain. They would be able to connect and transact on the sync domain if the protocol version set on the sync domain is set to 2 or lower. Note that if the participant and sync domain come from the same major release line, the sync domain will also support using protocol version 2. Thus, the sync domain could be configured such that the participant could connect to it

23.7.3.4 Minimum protocol version

Similar to how a sync domain operator is able to configure the protocol version spoken on a sync domain, a participant operator [is able to configure](#) a minimum protocol version for a participant. Configuring a minimum protocol version guarantees that a participant will only connect to a synchronizer that uses at least this protocol version or a newer one. This is especially desirable to ensure that a participant only connects to sync domains that have certain security patches applied or that support particular protocol features.

23.7.3.5 Support and bug fixes

Canton protocol major versions are supported for a minimum of 12 months from the release of the next major version. Within a major version, only the latest minor version receives security and bug fixes.

Chapter 24

Download and Install Canton

24.1 Choosing Open-Source or Enterprise Edition

The Canton distributed ledger is included with Daml Enterprise edition, or available as open source. Which role the application takes depends on the configuration. The main administration interface of the Canton application is the embedded console, which is part of the application.

Canton releases come in two variants: Open-Source or Enterprise. Both support the full Canton protocol, but differ in terms of enterprise and non-functional capabilities:

Table 1: Differences between Enterprise and Open Source Edition

Capability	Enterprise	Open-Source
Daml Synchronisation	Yes	Yes
Sub-Transaction Privacy	Yes	Yes
Transaction Processing	Parallel (fast)	Sequential (slow)
High Availability	Yes	No
Participant Query Store	Yes	No
Daml Shell	Yes	No
High Throughput via Microservices	Yes	No
Resource Management	Yes	No
Ledger Pruning	Yes	No
AWS KMS, GCP KMS and KMS Driver	Yes	No
Postgres Backend	Yes	Yes

Please follow below instructions in order to obtain your copy of Canton.

24.2 Downloading the Open Source Edition

The Open Source release is available from [Github](#). You can also use our Canton Docker images by following our [Docker instructions](#).

24.3 Downloading the Enterprise Edition

Enterprise releases are available on request (sales@digitalasset.com) and can be downloaded from the respective [repository](#), or you can use our Canton Enterprise Docker images as described in our [Docker instructions](#).

24.4 Install Canton

This guide will guide you through the process of setting up your Canton nodes to build a distributed Daml ledger. You will learn the following:

1. How to set up and configure a participant node
2. How to set up and configure an embedded or distributed sync domain
3. How to connect a participant node to a sync domain

A single Canton process can run multiple nodes, which is very useful for testing and demonstration. In a production environment, you typically run one node per process.

This guide uses the reference configurations you can find in the release bundle under `config` and explains how to leverage these examples for your purposes. Therefore, any file named in this guide refers to subdirectories of the reference configuration example.

24.4.1 Hardware Resources

Adequate hardware resources need to be available for each Canton node in a test, staging, or production environment. It is recommended to begin with a potentially over-provisioned system. Once a long running, performance benchmark has proven that the application's NFRs can be met (e.g., application request latency, PQS query response time, etc.) then decreasing the available resources can be tried, with a follow up rerun of the benchmark to confirm the NFRs can still be met. Alternatively, if the NFRs are not met then the available resources should be increased.

As a starting point, the minimum recommended resources are:

- The physical host, virtual machine, or container has 6 GB of RAM and at least 4 CPU cores.
- The JVM has at least 4 GB RAM.

Also, you may want to add `-XX:+UseG1GC` to force the JVM to use the G1 garbage collector. Experience has shown that the JVM may use a different garbage collector in a low resource situation which can result in long latencies.

24.4.2 Downloading Canton

The Canton Open Source version is available from [Github](#).

Daml Enterprise includes an enterprise version of the Canton ledger. If you have entitlement to Daml Enterprise you can download the enterprise version of Canton by following the [Installing Daml Enterprise instructions](#) and downloading the appropriate Canton artifact.

You can also use the Daml Enterprise Canton Docker images by following our [Docker instructions](#).

24.4.3 Your Topology

The first question we need to address is what the topology is that you are going after. The Canton topology is made up of parties, participants and sync domains, as depicted in the following figure.

The Daml code runs on the participant node and expresses smart contracts between parties. Parties are hosted on participant nodes. Participant nodes synchronize their state with other participant nodes by exchanging messages with each other through sync domains. Sync domains are nodes that integrate with the underlying storage technology such as databases or other distributed ledgers. As the Canton protocol is written in a way that assumes that participant nodes don't trust each other, you would normally expect that every organization runs only one participant node, except for scaling purposes.

If you want to build up a test network for yourself, you need at least a participant node and a sync domain.

The following instructions assume that you are running all commands in the root directory of the release bundle:

```
cd ./canton-<type>-X.Y.Z
```

24.4.4 The Config Directory Contents

Important: This section applies to 2.8.1 and later releases.

The config directory contains a set of reference configuration files, one per node type:

```
.
├── config
│   ├── shared.conf, sandbox.conf, participant.conf, domain.conf, sequencer.
│   └── conf, mediator.conf
│       ├── jwt
│       ├── misc
│       ├── monitoring
│       ├── remote
│       ├── storage
│       ├── tls
│       └── utils
```

`participant.conf`: a participant node configuration

`sequencer.conf`, `mediator.conf`, `manager.conf`: a sequencer, mediator, and manager node configuration for a Daml Enterprise sync domain deployment.

`domain.conf`: an embedded sync domain, which runs the three sync domain processes in one node (the only open source sync domain option).

`sandbox.conf`: a simple setup for a single participant node connected to a single sync domain node, using in-memory stores for testing.

In addition, you'll find the following files and directories:

`shared.conf`: a shared configuration file that is included by all other configurations.

`jwt`: contains JWT configuration files for the Ledger API.

`misc`: contains miscellaneous configuration files useful for debugging and development.

`monitoring`: contains configuration files to enable metrics and tracing.

`remote`: contains configuration files to connect Canton console to remote nodes.

`storage`: a directory containing storage configuration files for the various storage options.

`tls`: contains TLS configuration files for the various APIs and a script to generate test certificates.

`utils`: contains utility scripts, mainly to set up the database.

24.4.5 Selecting your Storage Layer

In order to run any kind of node, you need to decide how and if you want to persist the data. You can choose not to persist data and instead use in-memory stores that are deleted on node restart, or you can persist data using `Postgres` or `Oracle` databases.

Note: Multiple versions of `Postgres` are tested for compatibility with `Canton` and `PQS` in traditional deployment configurations. `Postgres` comes in many varieties that allow NFR trade-offs to be made (e.g., latency Vs. read operation scaling Vs. HA Vs. cost). Not all of these variants are tested for compatibility but all are expected to work with `Canton` and `PQS`. However, sufficient application testing is required to ensure that the SLAs of the ledger API and `PQS` clients are met. In particular, serverless `Postgres` has transient behaviors which require a robust application testing process to verify that application SLAs are met (e.g., transaction latency is not greatly impacted by auto-scaling).

For this purpose, there are some storage [mixin configurations](#) (`config/storage/`) defined.

These storage mixins can be used with any of the node configurations. All the reference examples include the `config/shared.conf`, which in turn by default includes `postgres.conf`. Alternatively, the in-memory configurations just work out of the box without further configuration, but won't persist any data. You can change the include within `config/shared.conf`.

The mixins work by defining a shared variable, which can be referenced by any node configuration

```
storage = ${_shared.storage}
storage.parameters.databaseName = "canton_participant"
```

If you ever see the following error: `Could not resolve substitution to a value: ${_shared.storage}`, then you forgot to add the persistence mixin configuration file.

Note: Please also consult the more [detailed section on persistence configurations](#).

`Canton` will manage the database schema for you. You don't need to create any tables or indexes.

24.4.5.1 Persistence using Postgres

While in-memory is great for testing and demos, for any production use, you'll need to use a database as a persistence layer. Both the community version and the enterprise version support `Postgres` as a persistence layer. `Daml Enterprise` also supports [Oracle as the persistence backend](#), but `Postgres` is recommended, which is used in the following instructions.

Make sure you have a running `Postgres` server. Create one database per node.

`Canton` is tested on a selection of the [currently supported Postgres versions](#). See the [Canton release notes](#) for the specific `Postgres` version used to test a particular `Canton` release.

Creating the Database and the User

In `util/postgres` you can find a script `db.sh` which helps configure the database, and optionally start a Docker-based Postgres instance. Assuming you have [Docker](#) installed, you can run:

```
cd ./config/util/postgres
./db.sh start [durable]
./db.sh setup
```

The `db.sh` will read the connection settings from `config/util/postgres/db.env` if they aren't already set by environment variables. The script will start a non-durable Postgres instance (use `start durable` if you want to keep the data between restarts), and create the databases defined in `config/util/postgres/databases`.

Other useful commands are:

- `create-user`: To create the user as defined in `db.env`.
- `resume`: To resume a previously stopped Docker-based Postgres instance.
- `drop`: Drop the created databases.

Configure the Connectivity

You can provide the connectivity settings either by editing the file `config/storage/postgres.conf` or by setting respective environment variables (see the file for which ones need to be set):

```
export POSTGRES_HOST="localhost"
export POSTGRES_USER="test-user"
export POSTGRES_PASSWORD="test-password"
export POSTGRES_DB=postgres
export POSTGRES_PORT=5432
```

Tuning the Database

Please note that Canton requires a properly sized and correctly configured database. Please consult the [Postgres performance guide](#) for further information.

24.4.6 Generate the TLS Certificates

The reference example configurations use TLS to secure the APIs. You can find the configuration files in `config/tls`. The configuration files are split by different APIs. The configuration files are:

- `tls-ledger-api.conf`: TLS configuration for the Ledger API, exposed by the participant node.
- `mtls-admin-api.conf`: TLS configuration for the Administration API, exposed by all node types.
- `tls-public-api.conf`: TLS configuration for the Public API, exposed by the sequencer and sync domain node.

The client authentication on the Public API is built in and cannot be disabled. It uses specific signing keys associated with the node's identity. The Ledger API supports [JWT based authentication](#). On the Admin API, you can enable mTLS. Please consult the [TLS documentation section](#) for further information.

If you want to start with a simple setup, you can use the provided script `config/tls/gen-test-certs.sh` to generate a set of self-signed certificates (which must include the correct SAN entries for the address the node will bind to).

Alternatively, you can also skip this step by commenting out the TLS includes in the respective configuration files.

24.4.7 Setting up a Participant

Start your participant by using the reference example `config/participant.conf`:

```
./bin/canton [daemon] -c config/participant.conf
```

The argument `daemon` is optional. If omitted, the node will start with an interactive console. There are various command line options available, for example to further tune the [logging configuration](#).

Note: By default, the node will initialize itself automatically using the identity commands [Topology Administration](#). As a result, the node will create the necessary keys and topology transactions and will initialize itself using the name used in the configuration file. Please consult the [identity management section](#) for further information.

This was everything necessary to start up your participant node. However, there are a few steps that you want to take care of in order to secure the participant and make it usable.

24.4.7.1 Secure the APIs

1. By default, all APIs in Canton are only accessible from localhost. If you want to connect to your node from other machines, you need to bind to `0.0.0.0` instead of localhost. You can do this by setting `address = 0.0.0.0` or to the desired network name within the respective API configuration sections.
2. All nodes are managed through the administration API. Whenever you use the console, almost all requests will go through the administration API. It is recommended that you set up mutual TLS authentication as described in the [TLS documentation section](#).
3. Applications and users will interact with the participant node using the ledger API. We recommend that you secure your API by using TLS. You should also [authorize your clients using JWT tokens](#). The reference configuration contains a set of configuration files in `config/jwt`, which you can use as a starting point.

24.4.7.2 Configure Applications, Users and Connection

Canton distinguishes static from dynamic configuration.

[Static configuration](#) are items which are not supposed to change and are therefore captured in the configuration file. An example is to which port to bind to.

Dynamic configuration are items such as Daml archives (DARs), sync domain connections, or parties. All such changes are effected through [console commands](#) (or the [administration APIs](#)).

If you don't know how to connect to sync domains, onboard parties, or provision Daml code, please read the [getting started guide](#).

24.4.8 Setting up a Synchronization Domain

Your participant node is now ready to connect to other participants to form a distributed ledger. The connection is facilitated by a sync domain, which is formed by three separate processes:

- a sequencer, which is responsible for ordering encrypted messages
- a mediator, which is responsible for aggregating validation responses by the individual participants
- a sync domain manager, which is responsible for verifying the validity of topology changes (distributed configuration changes) before they are distributed on the sync domain

These nodes don't store any ledger data, but just facilitate the communication between the participants.

In order to set up a sync domain, you need to decide what kind of driver you want to use for the sequencer. Drivers are provided for different infrastructure types. These drivers have different levels of fidelity in terms of trust and performance. Your current options are the following:

1. Postgres-based sync domain
2. [Oracle-based sync domain](#)
3. Hyperledger Fabric-based sync domain
4. Ethereum-based sync domain

In the near future, there will also be a native Canton BFT driver (which will be used for the [Canton Network](#)).

This section explains how to set up a Postgres-based synchronization sync domain. Please consult [the Enterprise driver section](#) with respect to the other drivers.

24.4.8.1 Using an Embedded Synchronization Domain

The simplest way to run a sync domain is to use the embedded configuration which runs all three processes in a single node. Using the same storage (but different database name) as configured for the participant node, you can start the sync domain using:

```
./bin/canton -c config/domain.conf
```

The embedded sync domain is your only choice if you are using the community version of Canton. It supports crash recovery, but not high availability.

24.4.8.2 Using Microservices

If you are using Daml Enterprise, you can start the sync domain processes as separate microservices:

```
./bin/canton daemon -c config/[mediator|sequencer|manager].conf
```

Before the nodes work together, they need to be initialized and connected. Consult the detailed guide [on how to bootstrap a sync domain](#).

Generally, you can connect the nodes using either the embedded console (if they run in the same process) or through the remote console:

```
./bin/canton -c config/remote/mediator.conf,config/remote/manager.conf,config/  
↪remote/sequencer.conf
```

Subsequently, just run the bootstrap command:

```
manager.setup.bootstrap_domain(sequencers.all, mediators.all)
```

Connect the Participant

The final step is to connect the participant to the sync domain. Refer to [the connectivity guide](#) for detailed instructions. In the simplest case, you just need to run the following command in the participant's console:

```
participant.domains.connect("domain", "https://localhost:10018", certificatesPath=
↳ "config/tls/root-ca.crt")
```

The certificate is explicitly provided, as the self-signed test certificates are not trusted by default.

24.4.8.3 Secure the APIs

1. As with the participant node, all APIs bind by default to localhost. If you want to connect to your node from other machines, you need to bind to the right interface or to 0.0.0.0.
2. The administration API should be secured using client certificates as described in [TLS documentation section](#).
3. The public API needs to be properly secured using TLS. Please follow the [corresponding instructions](#).

24.4.8.4 Next Steps

The above configuration provides you with an initial setup. Without going into details, the next steps would be:

1. Control who can join the sync domain by [configuring the sync domain to be permissioned](#) (default is everyone can join).
2. Create high availability setups for [your sync domain](#) or [your participants](#).

24.4.9 Multi-Node Setup

If desired, you can run many nodes in the same process. This is convenient for testing and demonstration purposes. You can either do this by listing several node configurations in the same configuration file or by invoking the Canton process with several separate configuration files (which get merged together).

```
./bin/canton -c config/participant.conf -c config/sequencer.conf,config/mediator.
↳ conf -c config/manager.conf
```

24.5 Work With the Docker Containers

Note: Please note that the images have moved from `digitalasset-canton-enterprise-docker.jfrog.io/digitalasset/canton-enterprise` to `digitalasset-docker.jfrog.io/canton-enterprise` as per version 2.8.0. The old images will remain, but new versions won't be added to the old repository. The open source Canton Docker image is no longer available.

24.5.1 Obtaining the Docker Images

The Canton Docker images are available for the Daml Enterprise. You can download them using

```
docker login digitalasset-docker.jfrog.io
docker pull digitalasset-docker.jfrog.io/canton-enterprise[:version]
```

The version is optional, and the latest version is used by default. The version `dev` is the the current main build.

24.5.2 Starting Canton

The `canton` executable is the default image entry point so all examples using `bin/canton` can simply substitute that with `docker run digitalasset/canton`.

For example, to run a command in interactive console mode, defining a participant on the fly:

```
docker run --rm -it digitalasset-docker.jfrog.io/canton-enterprise:latest \
  --no-tty -C canton.participants.p.ledger-api.port=1234
```

The `--rm` option ensures that the container is removed when the `canton` process exits. The `-it` options start the container interactively and provide access to our running console. The `-no-tty` option deactivates the `tty` mode, as the console is not usable with that mode engaged.

By default Docker will pull the `latest` tag containing the latest Canton release. As Docker will only automatically pull `latest` once, ensure you have the latest version by periodically running `docker pull digitalasset-docker.jfrog.io/canton-enterprise`.

24.5.3 Configuring Logging and Health Probes

The default convention with logging of containers is to have the process to log to `stdout`. The logging behaviour of Canton can be changed, using appropriate [command line flags](#), such as `--log-profile=container`. The Docker images include a gRPC health probe `/usr/local/bin/grpc_health_probe`, which can be used to setup health checks for Kubernetes.

24.5.4 Administrating the Running Node

In a Docker based environment, Canton should be run in `daemon` mode, while a [remote console](#) can be used to interact with the node.

24.5.5 Exposing the Ledger API or Admin API to the host machine

Applications using Canton typically need access to the Ledger or Admin API to read from and write to the ledger. Each participant binds the Ledger API to the port specified at the configuration key: `ledger-api.port`. For `participant1` in the simple topology example this is set to port 5011.

To expose the Ledger API to port 5011 on the host machine, run Docker with the following options:

```
docker run --rm -it \
  -p 5011:5011 \
  digitalasset-docker.jfrog.io/canton-enterprise --no-tty \
  -C canton.participants.participant1.ledger-api.address=0.0.0.0 \
  -C canton.participants.participant1.ledger-api.port=5011 \
```

The Ledger API port for each participant needs to be mapped separately. The same applies to the Admin API.

24.5.6 Supplying custom configuration and DARs

To expose files to the Canton container, you must specify a volume mapping from the host machine to the container.

For example, if you have the local directory `my-application` containing your custom Canton configuration and DAR:

```
docker run --rm -it \
  --volume "$PWD/my-application:/canton/my-application" \
  digitalasset-docker.jfrog.io/canton-enterprise daemon \
  --config /canton/my-application/my-config.conf
```

DARs can be loaded using the same container local path or by using the remote console access.

24.5.7 Running Postgres in Docker

Canton requires an appropriate database to persist data. For this purpose, such a database can also be run in a Docker container using the following, helpful command:

```
docker run -d --rm --name canton-postgres --shm-size=256mb --publish 5432:5432 -e \
  POSTGRES_USER=test-user \
  -e POSTGRES_PASSWORD=test-password postgres:14.8-bullseye postgres -c max_ \
  connections=500
```

Please note that the `--publish` command allows us to pick the target port which we have to define in the Canton configuration file. The `--rm` will delete the data store once the Docker container is killed. This is useful for short-term tests. The `--shm-size 256mb` is necessary as Docker will allocate only 64mb of shared memory by default which is insufficient for the way Canton uses Postgres.

Note that you also need to create the databases yourself, which for Postgres you can do using `psql`

```
PGPASSWORD=test-password psql -h localhost -U test-user << EOF
CREATE DATABASE participant1;
GRANT ALL ON DATABASE participant1 TO CURRENT_USER;
EOF
```

The tables will be managed automatically by Canton. The `psql` solution works also if you run multiple nodes on one Postgres database which all require separate databases. If you run just one node against one database, you can avoid using `psql` by adding `--POSTGRES_DB=participant1` to above Docker command.

24.6 Set Configuration Options

Canton differentiates between static and dynamic configuration. Static configuration is immutable and therefore has to be known from the beginning of the process. For a static configuration, examples would be the connectivity parameters to the local persistence store or the port the admin-apis should bind to. On the other hand, connecting to a sync domain or adding parties are not matters of static configuration and therefore are not set via the config file but through [console commands](#) (or the [administration APIs](#)).

The configuration files themselves are written in [HOCON](#) format with some extensions:

Durations are specified scala durations using a `<length><unit>` format. Valid units are defined by [scala](#) directly, but behave as expected using `ms`, `s`, `m`, `h`, `d` to refer to milliseconds, seconds, minutes, hours and days. Durations have to be non-negative in our context.

Canton does not run one node, but any number of nodes, be it sync domains or participant nodes in the same process. Therefore, the root configuration allows to define several instances of sync domains and participant nodes together with a set of general process parameters.

A sample configuration file for two participant nodes and a single sync domain can be seen below.

```
canton {
  participants {
    participant1 {
      storage.type = memory
      admin-api.port = 5012
      ledger-api.port = 5011
    }
    participant2 {
      storage.type = memory
      admin-api.port = 5022
      ledger-api.port = 5021
      ledger-api.synchronize-vetting-on-upload = true
    }
  }
  domains {
    mydomain {
```

(continues on next page)

(continued from previous page)

```

    init.domain-parameters.protocol-version = 7
    storage.type = memory
    public-api.port = 5018
    admin-api.port = 5019
  }
}
// enable ledger_api commands for our getting started guide
features.enable-testing-commands = yes
}

```

24.6.1 Configuration reference

The Canton configuration file for static properties is based on [PureConfig](#). PureConfig maps Scala case classes and their class structure into analogue configuration options (see e.g. the [PureConfig quick start](#) for an example). Therefore, the ultimate source of truth for all available configuration options and the configuration file syntax is given by the appropriate scaladocs of the [CantonConfig](#) classes.

When understanding the mapping from scaladocs to configuration, please keep in mind that:

- CamelCase Scala names are mapped to lowercase-with-dashes names in configuration files, e.g. `domainParameters` in the scaladocs becomes `domain-parameters` in a configuration file (dash, not underscore).

- `Option[<scala-class>]` means that the configuration can be specified but doesn't need to be, e.g. you can specify a JWT token via `token=token` in a [remote participant configuration](#), but not specifying `token` is also valid.

24.6.2 Configuration Compatibility

The enterprise edition configuration files extend the community configuration. As such, any community configuration can run with an enterprise binary, whereas not every enterprise configuration file will also work with community versions.

24.6.3 Advanced Configurations

Configuration files can be nested and combined together. First, using the `include required` directive (with relative paths), a configuration file can include other configuration files.

```

canton {
  domains {
    include required(file("domain1.conf"))
  }
}

```

The `required` keyword will trigger an error, if the included file does not exist; without the `required` keyword, any missing files will be silently ignored. The `file` keyword instructs the configuration parser to interpret its argument as a file name; without this keyword, the parser may interpret the given name as a URL or classpath resource. By using the `file` keyword, you will also get the most intuitive semantics and most stable semantics of `include`. The precise rules for resolving relative paths can be found [here](#).

Second, by providing several configuration files, we can override configuration settings using explicit configuration option paths:

```
canton.participants.myparticipant.admin-api.port = 11234
```

If the same key is included in multiple configurations, then the last definition has highest precedence.

Furthermore, HOCON supports substituting environment variables for config values using the syntax `key = ${ENV_VAR_NAME}` or optional substitution `key = ${?ENV_VAR_NAME}`, where the key will only be set if the environment variable exists.

24.6.4 Configuration Mixin

Even more than multiple configuration files, we can leverage [PureConfig](#) to create shared configuration items that refer to environment variables. A handy example is the following, which allows for sharing database configuration settings in a setup involving several sync domains or participant nodes:

```
# Postgres persistence configuration mixin
#
# This file defines a shared configuration resources. You can mix it into your
# configuration by
# refer to the shared storage resource and add the database name.
#
# Example:
#   participant1 {
#     storage = ${_shared.storage}
#     storage.config.properties.databaseName = "participant1"
#   }
#
# The user and password is not set. You want to either change this configuration
# file or pass
# the settings in via environment variables POSTGRES_USER and POSTGRES_PASSWORD.
#
_shared {
  storage {
    type = postgres
    config {
      dataSourceClass = "org.postgresql.ds.PGSimpleDataSource"
      properties = {
        serverName = "localhost"
        # the next line will override above "serverName" in case the
#environment variable POSTGRES_HOST exists
        # which makes it optional
        serverName = ${?POSTGRES_HOST}
        portNumber = "5432"
        portNumber = ${?POSTGRES_PORT}
        # user and password are required
        user = ${POSTGRES_USER}
        password = ${POSTGRES_PASSWORD}
      }
    }
  }
  parameters {
    # If defined, will configure the number of database connections per
#node.
```

(continues on next page)

(continued from previous page)

```

        # Please note that the number of connections can be fine tuned for
        ↪participant nodes (see participant.conf)
        max-connections = ${?POSTGRES_NUM_CONNECTIONS}
        # If true, then database migrations will be applied on startup
        ↪automatically
        # Otherwise, you will have to run the migration manually using
        ↪participant.db.migrate()
        migrate-and-start = false
        # If true (default), then the node will fail to start if it can not
        ↪connect to the database.
        # The setting is useful during initial deployment to get immediate
        ↪feedback when the
        # database is not available.
        # In a production setup, you might want to set this to false to allow
        ↪uncoordinated startups between
        # the database and the node.
        fail-fast-on-startup = true
    }
}

```

Such a definition can subsequently be referenced in the actual node definition:

```

canton {
  domains {
    mydomain {
      storage = ${_shared.storage}
      storage.config.properties.databaseName = ${CANTON_DB_NAME_DOMAIN}
    }
  }
}

```

24.6.5 Multiple Synchronization Domains

A Canton configuration allows you to define multiple sync domains. Also, a Canton participant can connect to multiple sync domains. This is however only supported as a preview feature and not yet suitable for production use.

In particular, contract key uniqueness cannot be enforced over multiple sync domains. In this situation, we need to turn contract key uniqueness off by setting

```

canton {
  domains {
    alpha {
      // subsequent changes have no effect and the mode of a node can never be
      ↪changed
      init.domain-parameters {
        unique-contract-keys = false
        protocol-version = 7
      }
    }
  }
}

participants {

```

(continues on next page)

(continued from previous page)

```
participant1 {  
  // subsequent changes have no effect and the mode of a node can never be ☐  
  ↪changed  
  init.parameters.unique-contract-keys = false  
}  
}
```

Please note that the setting is final and cannot be changed subsequently. We will provide a migration path once multi-sync-domain functionality is fully implemented.

24.6.6 Fail Fast Mode

By default, Canton will fail to start if it cannot access some external dependency such as the database. This is preferable during initial deployment and development, as it provides instantaneous feedback, but can cause problems in production. As an example, if Canton is started with a database in parallel, the Canton process would fail if the database is not ready before the Canton process attempts to access it. To avoid this problem, you can configure a node to wait indefinitely for an external dependency such as a database to start. The config option below will disable the `fail fast` behavior for `participant1`.

```
canton.participants.participant1.storage.parameters.fail-fast-on-startup = "no"
```

This option should be used with care as, by design, it can cause infinite, noisy waits.

24.6.7 Init Configuration

Some configuration values are only used during the first initialization of a node and cannot be changed afterwards. These values are located under the `init` section of the relevant configuration of the node. Below is an example with some init values for a participant config

```
participant1 {  
  init {  
    // example settings  
    ledger-api.max-deduplication-duration = 1 minute  
    parameters.unique-contract-keys = false  
    identity.node-identifier.type = random  
  }  
}
```

The option `ledger-api.max-deduplication-duration` sets the maximum deduplication duration that the participant's [ledger configuration service](#) reports and uses for [command deduplication](#).

Important: [Daml Enterprise license](#) required

24.7 Set Up A Daml Domain With Enterprise Drivers

The Daml Enterprise edition of the Canton ledger provides the following drivers in addition to the PostgreSQL-based sync domain in the open-source edition.

Important: [Daml Enterprise license](#) required

24.7.1 Oracle Synchronization Domain

In Daml Enterprise, you can run a Canton sync domain (sequencer, mediator, sync domain manager nodes) based on an Oracle enterprise database.

Refer to the following section on how to set up Oracle for Canton as well as how to configure Canton to use an Oracle database.

[Installation and Configuration of Canton on Oracle](#)

Important: [Daml Enterprise license](#) required

24.7.2 Fabric Synchronization Domain

The Canton-on-Fabric integration runs a Canton sync domain where events are sequenced using the [Hyperledger Fabric](#) ledger.

24.7.2.1 Tutorial

To run the demo Canton Fabric deployment, you will need access to the following:

- a Daml Enterprise release for access to the example files and the Canton binary
- [Canton Enterprise docker repository](#) access, to obtain the Canton docker image

Also make sure to have docker and docker-compose installed.

The following example explains how to set up Canton on Fabric using a topology with 2 sequencer nodes, (belonging to two different organizations) a sync domain manager, a mediator, and two participant nodes.

The demo can be found in the examples directory of the Canton Enterprise release. Unpack the Canton Enterprise release and then `cd` into `examples/e01-fabric-domain/canton-on-fabric`.

Run the script `./run.sh full`.

The script will start the following:

1. A Fabric ledger with 2 peers and one orderer node.
2. Two Canton Sequencer nodes that interact with the Fabric ledger.
3. A Canton process running a Canton sync domain manager, a mediator, and 2 participants. The configuration for this Canton process is in `config/canton/demo.conf`

Once the script has finished setting up (you should see the `canton` service print `Successfully initialized Canton-on-Fabric` together with the Canton console startup message), you will be able to interact with the two participants using the config at `config/remote/demo.conf`.

You can start an instance of the Canton console to connect to the two remote participants (provided you have also installed Canton):

```
<<canton-release>>/examples/e01-fabric-domain/canton-on-fabric$ ../../../../bin/  
↪canton -c config/remote/demo.conf
```

You can then perform various commands in the Canton console:

```
@ remoteParticipant1.id  
res1: ParticipantId = PAR::participant1::012c7af9...  
  
@ remoteParticipant1.domains.list_connected  
res2: Seq[(com.digitalasset.canton.DomainAlias, com.digitalasset.canton.  
↪DomainId)] = List((Domain 'myDomain', myDomain::01dafa04...))  
  
@ remoteParticipant1.health.ping(remoteParticipant2)  
res3: concurrent.duration.Duration = 946 milliseconds
```

24.7.2.2 User Manual

The example files located at `examples/e01-fabric-domain/canton-on-fabric` provide you with more flexibility than running the basic demo just shown.

You will find our main script called `run.sh` in this directory. If you run the script, it will show you the help instructions with all the options that you can choose to run the deployment.

The demo deployment will by default use the Canton version from the release. If you wish to use a different version, you can specify it with the `CANTON_VERSION` environment variable. For example, `export CANTON_VERSION=2.5.1` to use Canton v2.5.1. You can choose `dev` for the latest main build of Canton.

Depending on which options you choose, it will run a docker-compose command using a different subset of the following docker-compose files below:

`docker-compose-ledger.yaml`: Sets up the Fabric ledger. You can see that there is a service called `ledger-setup` that is a service responsible for creating the crypto materials, setting up the channel and deploying the chaincode. It uses a customized and simplified version of the test-network from [fabric-samples](#) inside a docker container.

`docker-compose-blockchain-explorer.yaml`: Runs a [blockchain explorer](#) that allows visualizing the Fabric ledger on the browser.

`docker-compose-canton.yaml`: Runs all Canton components: a sync domain manager, a mediator, the two Fabric sequencer(s) and two participants.

The bootstrapping process of the distributed sync domain is done by the `docker-compose-canton.yaml` docker-compose file which uses the `config/canton/demo.canton` script. If you wish to learn more about this process please refer to [sync domain bootstrapping](#).

Run with Docker Compose

The script `run.sh` works by running `docker-compose` using a different combination of the `docker-compose` files shown above, depending on the arguments given to the script.

As was shown, to run Canton with two Fabric Sequencers in a multi-sequencer setup, run `./run.sh full`. That is equivalent to running the following `docker-compose` command:

```
<<canton-release>>/examples/e01-fabric-domain/canton-on-fabric$ COMPOSE_PROJECT_
↪NAME="fabric-sequencer-demo" docker-compose -f docker-compose-ledger.yaml -f
↪docker-compose-canton.yaml up
```

Note that you can at this point connect the remote participants to this setup just like in the demo from the tutorial.

Cleanup

When you're done running the sequencer, make sure to run `./run.sh down`. This will clean up all `docker` resources so that the next run can happen smoothly.

Using the Canton Binary instead of Docker

To run the full Canton setup separately outside of Docker (with the Canton binary or jar):

```
<<canton-release>>/examples/e01-fabric-domain/canton-on-fabric$ ./run.sh ledger
```

After a few seconds you should see the two peers and one orderer nodes are up by running `docker ps` and seeing two `hyperledger/fabric-peer` containers exposing ports 9051 and 7051 and one `hyperledger/fabric-orderer` exposing the port 7050. Next run the following:

```
<<canton-release>>/examples/e01-fabric-domain/canton-on-fabric$ ../../bin/
↪canton -c config/self-contained/demo.conf --bootstrap config/canton/demo.canton
```

To run the jar file instead of the Canton binary, simply replace `../../bin/canton` above with `java -jar ../../lib/canton-enterprise-*.jar`.

Blockchain Explorer

If you wish to start the [Hyperledger Blockchain Explorer](#) to browse activity on the running Fabric Ledger, add the `-e` flag when running `./run.sh`.

Alternatively you can use `docker-compose` as shown before and add `-f docker-compose-blockchain-explorer.yaml`.

You will then be able to see the explorer web UI in your browser if you go to `http://localhost:8080`.

You can start the explorer separately after the ledger has been started by simply running the following command:

```
<<canton-release>>/examples/e01-fabric-domain/canton-on-fabric$ COMPOSE_PROJECT_
↪NAME="fabric-sequencer-demo" docker-compose -f docker-compose-blockchain-
↪explorer.yaml up
```

(continues on next page)

Note that even when the explorer is working perfectly, it might output some error messages like the following which can be safely ignored:

```
[ERROR] FabricGateway - Failed to get block 0 from channel undefined : □  
↳ TypeError: Cannot read property 'toString' of undefined
```

24.7.2.3 Fabric Setup

The Fabric Sequencer operates on top of the Fabric Ledger and uses it as the source of truth for the state of the sequencer (all the messages and the order of them).

In order for The Fabric Sequencer to successfully operate on a given Fabric Ledger, that ledger must have been set up with at least one channel where the Canton Sequencer chaincode has been installed and the sequencer needs to be configured properly to have access to the ledger.

As mentioned previously, for our demo setup we use a slightly modified version of the `test-network` scripts from [fabric-samples](#) inside a docker container to setup a simple local docker-based Fabric network. This script uses many of the [Fabric CLI commands](#) to set up this network, such as [configtxgen](#), [peer channel](#), [peer chaincode](#), and [peer lifecycle](#). In a real-life scenario one might use this CLI to set up the ledger or some specific UI provided by a cloud service provider that hosts Blockchain services.

Regarding the chaincode setup, the Fabric Sequencer expects that the chaincode is initialized by calling the function `init` (no arguments needed) and with the `--isInit` flag turned on. You can find the chaincode source at `/ledger-setup/chaincode/src/github.com/digital-asset/sequencer`.

In order to configure a Fabric Sequencer in Canton, make sure to set `canton.sequencers.<your sequencer>.sequencer.type = "fabric"`. The rest of the Fabric sequencer-specific config will be under `canton.sequencers.<your sequencer>.sequencer.config`. Within this subconfig, you'll need to set the `user` key with Fabric client details so that the sequencer can invoke chaincode functions and read from the ledger. You'll also need to set `organizations` details which include peers and orderers connection details that the sequencer will have access to. You must define at least one peer that is from the same organization as your user.

The sequencer needs access to at least enough peers to fulfil the [chaincode endorsement policy](#). An endorsement policy that requires a single peer is enough and is what we recommend (more at [Endorsement Policies](#)).

It is possible to indicate the channel name with the `channel.name` key and the chaincode name with the `channel.chaincode.name` key (defaults to `sequencer`). This is all exemplified, including extensive commentary, in the config file used for the first sequencer of the demo, which you can find at `examples/e01-fabric-domain/canton-on-fabric/config/fabric/fabric-config-1.conf`.

By default, the sequencer application will start reading blocks from the ledger from the genesis block. We can signal a later starting point by setting `channel.chaincode.start-block-height` to a specific number in case the chaincode has been deployed much later than genesis.

Block Cutting Parameters and Performance

It is possible to configure the block cutting parameters of the ledger by changing the file at `ledger-setup/configtx/configtx.yaml`.

The relevant parameters are the following:

`Orderer.BatchTimeout`: The amount of time to wait before creating a block.
`Orderer.BatchSize.MaxMessageCount`: The maximum number of transactions to permit in a block (block size).

Note: In other kinds of Fabric Ledger setups, one should be able to configure these parameters in different ways.

If your use case operates under high traffic, you may benefit from increasing the block size in order to increase your throughput at the expense of latency. If you care more about latency and don't need to support high traffic, then decreasing block size will be of help.

Currently, we have set the values of 200ms for batch timeout and 50 for block size as it has empirically shown to be a good tradeoff after some rounds of long-running tests, but feel free to pick parameters that fit your use case best.

Note: See slide 17 of <http://www.mscs.mu.edu/~mascots/Papers/blockchain.pdf> for a discussion on block size influence on throughput and latency.

Authorization

When operating the Fabric infrastructure to support the Fabric Sequencer one may want to authorize only certain organizations to determine the sequencer's behavior.

Only the organizations included in the [Fabric Channel](#) will be able to operate on the ledger.

Fabric [Policies](#) can also be used to limit how the capabilities of organizations in the channel. See more on that under [Endorsement Policies](#) below.

Endorsement Policies

Fabric [Policies](#) can be used to define how members come to an agreement on accepting or rejecting changes to the network, a channel or a smart contract.

Versatile policies can be written using combinations of AND, OR and NOutOf ([more detail here](#)).

The most relevant kinds of policies for our purposes here are the [channel configuration policy](#) (defined at the channel level) and [endorsement policies](#) (defined at the chaincode level).

See other kinds of policies [here](#).

We recommend setting up a single peer endorsement policy.

We do not benefit from the chaincode endorsements because there is no mutable state in the chaincode or special logic that needs to be endorsed. We care more about correct ordering of blocks, which is taken care of by the ordering service. Because of that, there is no point in using more complex endorsement policies. A single peer endorsement policy also simplify configuration and increases availability. The demo we ship is configured like this (at `ledger-setup/configtx/configtx.yaml`, under `Application.Policies.Endorsement`.)

High Availability

When configuring the Fabric sequencer, make sure to provide access to at least enough peers to fulfill the [chaincode endorsement policy](#) that has been configured.

Access to additional peers may also be configured, to make the setup more highly available and to avoid a scenario where the crash of one peer would cause transactions to stop going through due to lack of enough endorsements.

If a client is connected to more than one Fabric Sequencer and each sequencer defines a different set of connections to Fabric peers (and orderers), the client will benefit from another level of availability. If of the sequencers is not healthy, the client will simply fail over to the ones that are still healthy.

Important: [Daml Enterprise license](#) required

24.7.3 Ethereum Synchronization Domain

24.7.3.1 Introduction

Daml Enterprise includes a Canton Ethereum Sequencer integration, which interacts via an Ethereum client with a smart contract `Sequencer.sol` deployed on an external Ethereum network. It uses the blockchain as a source of truth for sequenced events and is currently tested with the Ethereum client [Hyperledger Besu](#). The [architecture document](#) contains more details on the architecture of the integration.

24.7.3.2 The Ethereum Demo

Prerequisites

To run the demo, you will need access to a Daml Enterprise release, the [Canton docker repository](#), as well as having docker, docker-compose, and Hyperledger Besu ([instructions here](#)) installed.

Introduction

The demo Ethereum deployment can be found inside the examples directory of the Canton Enterprise release. Unpack the Canton Enterprise release and then `cd` into `examples/e03-ethereum-sequencer`.

The script `./run.sh` from the folder `examples` will create a new Besu testnet for the demo deployment and then start the demo. It has two scenarios: a simple and an advanced scenario. Both scenarios will start several dockerised services:

- An Ethereum testnet, using four Besu nodes with the QBFT consensus protocol. This is the same for the simple and advanced scenario.

- An instance of Canton. This includes two participants and a sync domain with one Ethereum sequencer for the simple scenario and two Ethereum sequencers for the advanced scenario. The respective Canton configurations are in `canton-conf/simple` and `canton-conf/advanced`.

The environment variable `CANTON_VERSION` is used to select the version of Canton to use for the demo deployment. This should normally be set to the version of Canton being used, but can alternatively be set to a different version or `dev` for the latest main build of Canton.

Simple Scenario

The simple scenario uses one Canton sequencer whose corresponding `Sequencer.sol` contract is deployed using a script before startup. It uses mutual TLS between Canton and Besu.

Advanced Scenario

The advanced scenario uses two Canton sequencers, mutual TLS, Ethereum wallets and uses the same script deploying `Sequencer.sol`.

Running a scenario

To start the simple or advanced demo scenario run:

```
<<canton-release>>/examples/e03-ethereum-sequencer$ CANTON_VERSION=<your version>
➔ ./run.sh simple
```

or

```
<<canton-release>>/examples/e03-ethereum-sequencer$ CANTON_VERSION=<your version>
➔ ./run.sh advanced
```

A new Besu testnet will be created and the demo will begin running with the created testnet. Once the demo is initialized and running, it will print out

```
*****
Successfully initialized Canton-on-Ethereum
*****
```

You will then be able to interact with the two participants via their ledger APIs (or their admin APIs) respectively running on ports 5011 and 5021 (or 5012 and 5022).

For example, you can start an instance of the Canton console to connect to the two remote participants. You can find the Canton binary in `bin/canton` of the Canton Enterprise release artifact.

```
<<canton-release>>/examples/e03-ethereum-sequencer$ ../../bin/canton -c canton-
➔ conf/remote.conf
```

You can then perform various commands in the Canton console:

```
@ remoteParticipant1.id
res5: ParticipantId = ParticipantId(
  UniqueIdentifier(Identifier("participant1"), Namespace(Fingerprint(
➔ "01e69a39e2c821fc98eae22994b47084162122a01ebcb16dfb2514ccafcedd43d")))
)
@ remoteParticipant2.id
```

(continues on next page)

(continued from previous page)

```
res6: ParticipantId = ParticipantId(
  UniqueIdentifier(Identifier("participant2"), Namespace(Fingerprint(
    ↪ "014aeb29dddf83678bc6f1194c363c6f0d18d3a6c9655927a7fb5adc84ec0532c")))
)

@ remoteParticipant1.domains.list_connected
res7: Seq[(com.digitalasset.canton.DomainAlias, com.digitalasset.canton.
  ↪ DomainId)] = List(
  (Domain 'mydomain', mydomain::01537eb8...)
)

@ remoteParticipant1.health.ping(remoteParticipant2)
res8: concurrent.duration.Duration = 968 milliseconds
```

To shutdown and remove all Docker containers, you can execute `stop-with-purge.sh`:

```
<<canton-release>>/examples/e03-ethereum-sequencer$ ./stop-with-purge.sh
```

Generating a Clean Testnet

The directory `examples/e03-ethereum-sequencer/qbft-testnet` contains the script `generate-testnet.sh`. This automatically generates a clean Besu network in a `testnet` directory, including new randomized private keys. `generate-testnet.sh` is automatically called by `run.sh` but you may want to understand and edit it to create your own custom Besu deployment.

When `generate-testnet.sh` is run:

- The state from any previous runs of `generate-testnet.sh` is deleted and a new directory `testnet` is created.

- A genesis file, a set of keys for four Besu nodes and TLS certificates for Canton and Besu are automatically generated. These can be found in the folders `testnet/nodei` (where *i* has values 1 to 4) and `testnet/tls`, respectively.

- The four Besu nodes are started via calling `start-node.sh`.

If the script finds Besu keys or TLS certificates in the same directory as the script, it will attempt to reuse them. This significantly reduces startup time if you want to test different network configurations.

The generated Besu testnet has been configured largely following these tutorials:

- <https://besu.hyperledger.org/en/stable/private-networks/tutorials/qbft/>
- and <https://besu.hyperledger.org/en/stable/HowTo/Configure/FreeGas/>

Note that the RPC HTTP APIs `ETH`, `TXPOOL`, and `WEB3` of Besu need to be enabled when using the Besu driver.

Customization of the Besu network

The parameters of the generated testnet can be changed by modifying the `genesis.json` file defined inline in `generate-testnet.sh`. Similarly, the CLI options with which the Besu nodes are started can be configured by modifying `start-node.sh`

Customization of the Demo Configuration

You can also modify the Canton configurations and bootstrap scripts for the demo if, for example, you want to [add persistence to the participants](#). The Canton configurations are found in

```
canton-conf/simple and
canton-conf/advanced
```

for the simple and advanced scenarios, respectively. If you want to change Ethereum-specific configuration options, (e.g. to configure a different wallet) please refer to the documentation section on this page and the corresponding [scaladoc configuration option](#).

Note that if you change port mappings in the Canton config file you may also need to update the corresponding docker compose files in directory `docker-compose/`.

24.7.3.3 Error Codes

The Ethereum Sequencer application auto-detects many common configuration and deployment issues and logs them as warnings or errors with [error codes](#). If you see such a warning or error, please refer to the [respective error code explanation and resolution](#).

24.7.3.4 TLS Configuration

Canton supports mutual TLS between Canton and Ethereum client nodes and the demo contains an example of how to configure this. Concretely, the TLS configuration for Canton expects a key store and the path to the Ethereum TLS certificates:

```
_tls {
  canton-key-store {
    path="/canton/testnet-working/tls/canton_store.p12"
    password="password"
  }
  ethereum-certificate-path = "/canton/testnet-working/tls/besu_cert.pem"
}

canton.sequencers.ethereumSequencer1.sequencer.config.tls = ${_tls}
```

The demo also contains the utility script `qbft-testnet/generate-tls.sh` which is called by `generate-testnet.sh` and writes the TLS certificates to `qbft-testnet/testnet/tls`. These certificates are then used by `start-node.sh`.

If Canton is not configured to use TLS with an Ethereum node, it will attempt to communicate via a HTTP endpoint on the Ethereum node (and HTTPS for TLS).

For more details on the Canton configuration, please see the scaladocs of the [TLS configuration](#). For more details on how to configure Besu to accept TLS connections (as done in the demo, see especially file `start-node.sh`), please see the [Besu documentation](#).

24.7.3.5 Ethereum Accounts and Wallets

Canton allows you to configure an Ethereum wallet (and therefore an Ethereum account) to be used by an Ethereum sequencer application. The configured Ethereum account is used for all interactions of the Ethereum sequencer with the Ethereum blockchain. If no Ethereum account is explicitly configured, a random Ethereum account is used.

Note: When multiple Ethereum sequencer applications interact with the same `Sequencer.sol` instance, each Ethereum Sequencer process needs to use a separate Ethereum account. Otherwise, transactions may get stuck due to nonce mismatches.

Canton allows configuring a wallet in [UTC JSON](#) and [BIP 39 format](#).

The Ethereum demo includes examples of mix-in wallet configuration files for both formats; the UTC JSON-based wallet mix-in looks as follows:

```
canton.sequencers.ethereumSequencer2.sequencer.config.wallet {  
  type = "utc-json-wallet"  
  password = "password"  
  wallet-path = "/canton/advanced/utc-wallet.json"  
}
```

with following `utc-wallet.json`:

```
canton.sequencers.ethereumSequencer2.sequencer.config.wallet {  
  type = "utc-json-wallet"  
  password = "password"  
  wallet-path = "/canton/advanced/utc-wallet.json"  
}
```

The BIP39-based wallet mix-in looks as follows:

```
canton.sequencers.ethereumSequencer2.sequencer.config.wallet {  
  type = "utc-json-wallet"  
  password = "password"  
  wallet-path = "/canton/advanced/utc-wallet.json"  
}
```

For more details, please refer to the [Canton scaladoc documentation](#).

24.7.3.6 Deployment of the Sequencer Contract

Manual deployment

If you want to manually deploy `Sequencer.sol` to your Ethereum network, the file `<<canton-release/examples/e03-ethereum-sequencer/qbft-testnet/Sequencer-binary` contains the compiled Solidity code you need to deploy. For Besu, for example, you will need to specify the contents of `Sequencer-binary` in `"code": "..."` as documented [here](#).

24.7.3.7 Requirements for the Ethereum Network

The Canton Ethereum integration is currently tested with the [QBFT consensus protocol](#) as illustrated in the demo. Other setups are possible, but they should fulfill the following requirements:

- The Ethereum client [Hyperledger Besu](#) (version in release notes tested, but any sibling sub-minor version should be OK) should be used and expose the RPC HTTP APIs `ETH`, `TXPOOL`, and `WEB3`.

- Currently, a free gas network is required. This means setting the gas price to zero.

- The block size limit (often measured in gas, and sometimes referred to as the ‘gas limit’) must be larger than any message to be sequenced. It is recommended to set this parameter as high as possible.

- The contract size limit must be big enough for the Canton Ethereum sync domain to store all required states for sequencing messages. It is recommended to set this parameter as high as possible.

- Proof of authority protocols are recommended over proof of work.

- Currently, consensus protocols must have [immediate finality](#). This means that ledger forks should not occur with the chosen consensus protocol.

Furthermore, we also have some suggestions to improve throughput and latency irrespective of the choice of Ethereum client.

Throughput

Generally, the throughput of a Canton system using Ethereum-based sequencers is limited by the throughput of the Ethereum client. Thus, if an Ethereum-based sequencer does not deliver the desired throughput, the throughput and deployment of the Ethereum clients should be optimized in the first instance. For Besu performance optimization, some recommendations can be found [in the Besu documentation](#) - in particular, it is crucial to use a fast storage media.

Latency

Within a Canton transaction, there are three sequential sequencing steps, that is, a single Canton transaction leads to at least three sequential messages sent to the sequencer. This is illustrated, e.g., in the *message sequence diagram* of the Canton 101 section. As a result, a Canton transaction also leads to at least three Ethereum transactions within three different blocks. Thus, to achieve relatively low latencies, the Ethereum network networks must be configured with a frequent block mining frequency (configured via `blockperiodseconds` in Besu) and ideally co-located with the Canton sequencer node. A block mining frequency of at least one block per second is recommended.

24.7.3.8 Trust Properties of the Ethereum Sequencer Integration

The demo integration uses two participants and two different Ethereum Sequencer nodes. Each participant chooses its preferred Ethereum Sequencer node, and this node performs reads and writes on behalf of the participant. Therefore, each participant must trust its chosen Ethereum Sequencer node. Additionally, each participant must trust some proportion of the nodes in the Ethereum network as determined by the consensus protocol.

24.7.3.9 High Availability

The Ethereum sequencer currently supports connecting to just one Ethereum client node. The sequencer node monitors its dependencies and signals to its users any potential issue that would prevent it from operating correctly.

The health information is exposed as a [Grpc Health service](#); sequencer clients use this in order to determine whether a sequencer is usable or not. The health state is also included in the sequencer status accessible on the Admin API. In order to benefit from higher availability, clients must connect to multiple sequencers such that they can fail over automatically to healthy sequencers once some of them become unhealthy.

The following health checks are implemented:

- Can the sequencer node connect and read from the Ethereum RPC API by calling the [eth_syncing](#) method and check whether a result can be obtained?
- Can the sequencer node connect to its database?

Chapter 25

High Availability (HA)

The following sections cover how High Availability (HA) is implemented in Daml solutions.

25.1 Intro to HA in Canton

This section provides an overview of High Availability (HA) in Canton, how participant nodes are replicated, and how HA is implemented on the sync domain.

25.1.1 Overview

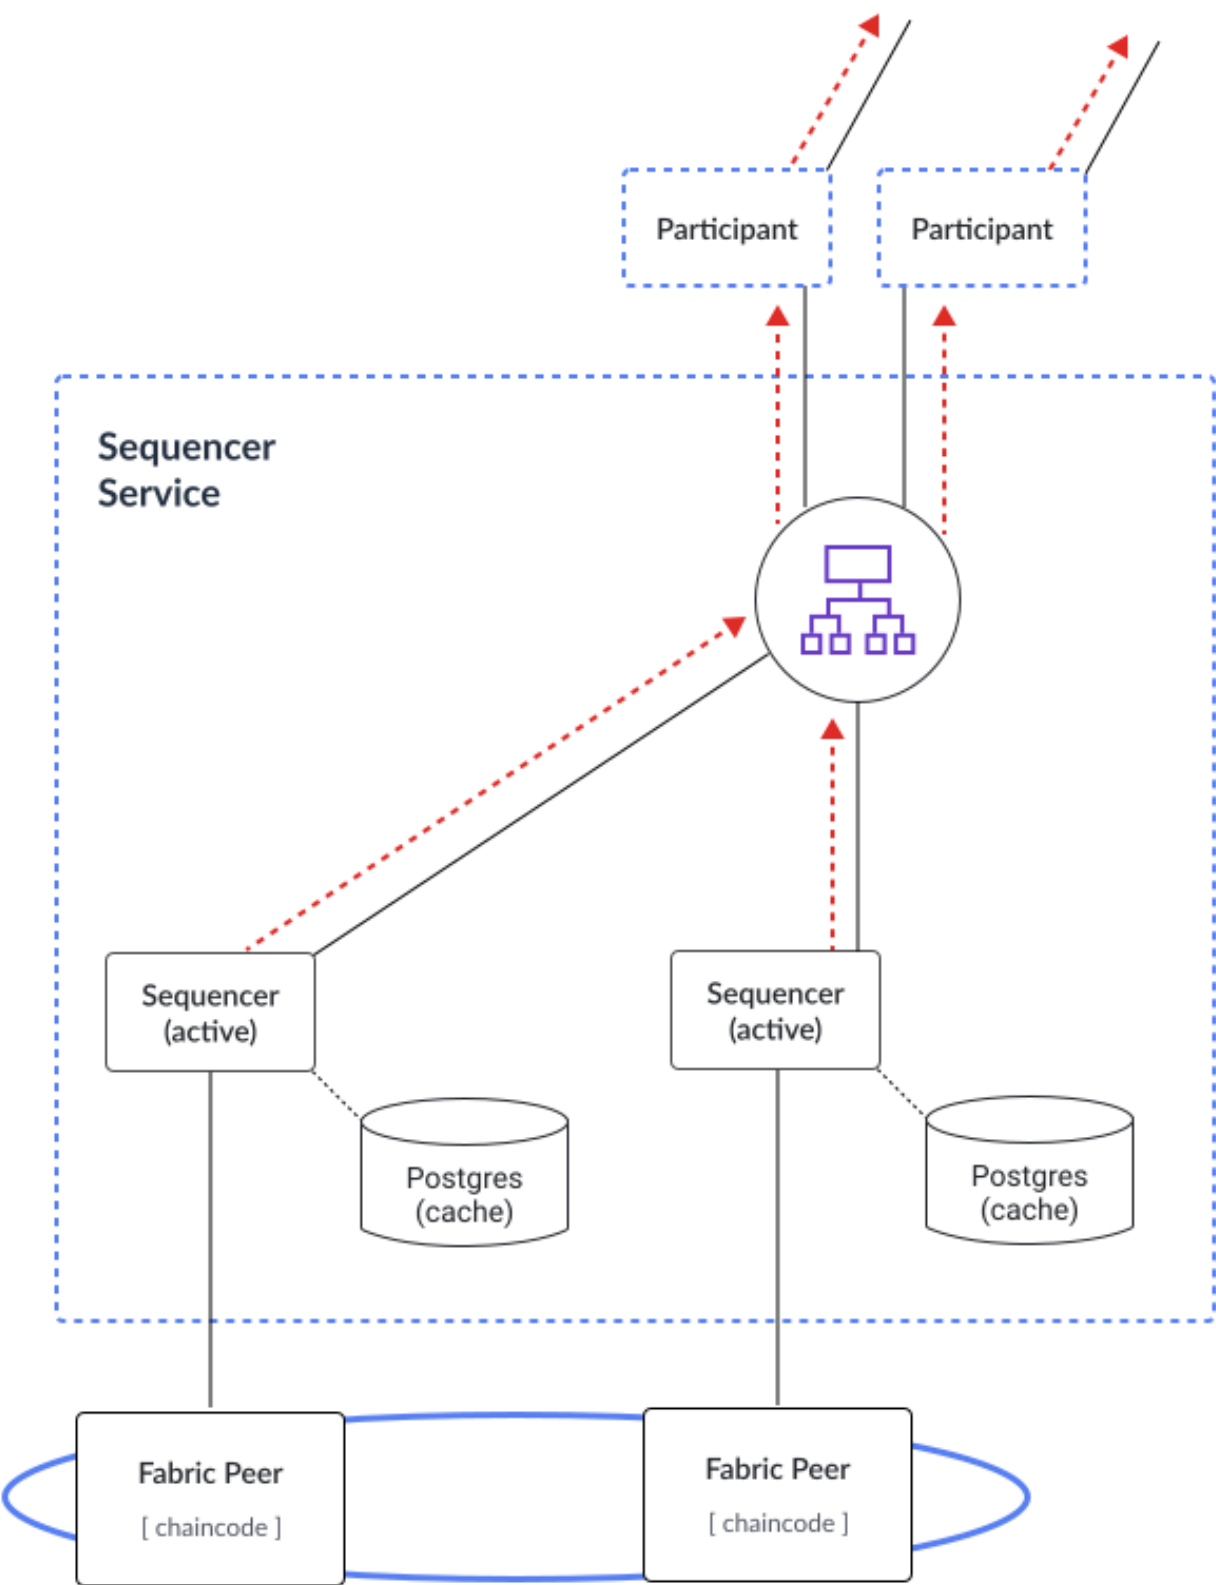

High Availability (HA) is the elimination of single points of failure to ensure that applications continue to operate when a component they depend on, such as a server, fails.

In Daml solutions, HA focuses on the following components running in separate processes:

Participant nodes

Sync domains:

- Sequencer
- Mediator
- Sync Domain Topology Manager

25.1.1.1 Participant Nodes

The availability of a participant node shouldn't affect the availability of another participant node, except for the following workflows:

1. Where they are both involved.
2. When they have distinct visibility configurations, i.e. they manage different parties involved in the workflow.

For example, if they both host the same party, transactions involving the party can continue as long as either of them is available.

Note: An application operating on behalf of a party cannot transparently failover from one participant node to another due to the difference in offsets emitted on each participant.

25.1.1.2 Synchronization Domains

A participant node's availability is not affected by the availability of the sync domain, except for workflows that use the sync domain. This allows participant nodes and sync domains to take care of their HA separately.

25.1.1.3 Replication

To achieve HA, components replicate. All replicas of the same component have the same trust assumptions, i.e. the operators of one replica must trust the operators of the other replicas.

25.1.1.4 Databases

In general, when a component is backed by a database/ledger, the component's HA relies on the HA of the database/ledger. Therefore, the component's operator must handle the HA of the database separately.

All database-backed components are designed to be tolerant of temporary database outages. During the database failover period, components halt processing until the database becomes available again, resuming thereafter.

Transactions that involve these components may time out if the failover takes too long. Nevertheless, they can be safely resubmitted, as command deduplication is idempotent.

25.1.1.5 Health Check

Canton components expose a [health endpoint](#), for checking the health of the components and their subcomponents.

Important: [Daml Enterprise license](#) required

25.1.2 Active-Passive Participant Node Configuration

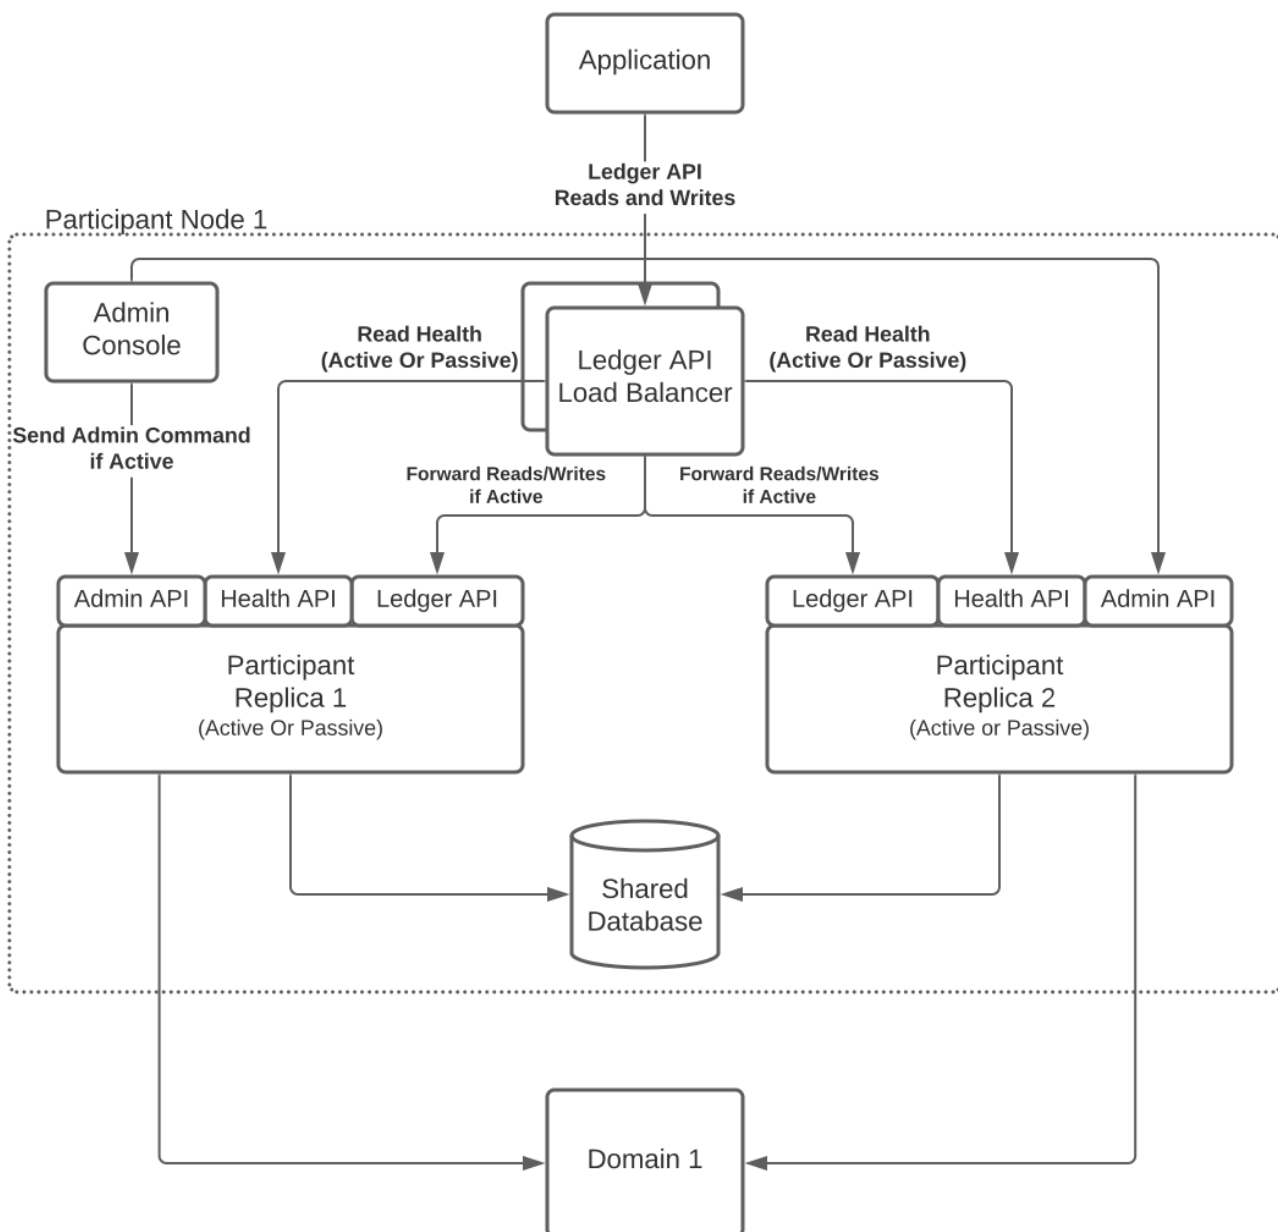

Participant nodes are configured in an active-passive configuration with a shared database.

The active node services requests while a passive node waits in warm-standby mode, ready to take over if the active node fails.

25.1.2.1 High-Level System Design

A logical participant node - shown below - contains an active and passive physical participant node with a shared database.

Each participant node exposes its own Ledger API although these can be hidden by a single Ledger API endpoint running on a highly available load balancer.

The load balancer configuration contains details of all Ledger API server addresses and the ports for

the participant node replicas. Nodes expose their active or passive status via a health endpoint. The load balancer can also detect when the backend port becomes unreachable, i.e. when the ledger API server is shut down as a node goes from active to passive.

Periodically polling the health API endpoint, the load balancer identifies a node as offline if it is passive. Requests are then *only* sent to the active participant node.

Important: The health endpoint polling frequency can affect the failover duration.

During failover, requests may still go to the former active node; which rejects them. The application retries until the requests are forwarded to the new active node.

Shared Database

The nodes require a shared database for the following reasons:

1. To share the command ID deduplication state of the Ledger API command submission service. This prevents double submission of commands in case of failover.
2. To obtain consistent ledger offsets without which the application cannot seamlessly failover. The database stores ledger offsets in a non-deterministic manner based on the insertion order of publishing events in the multi-sync-domain event log.

25.1.2.2 Leader Election

A leader election establishes the active node. The participant node sets the chosen active node as the single writer to the shared database.

Exclusive, application-level database locks - tied to the database connection lifetime - enforce the leader election and set the chosen node as the single writer.

Note: Alternative approaches for leader election, such as Raft, are unsuitable because the leader status can be lost between the leader check and the use of the shared resource, i.e. writing to the database. Therefore, we cannot guarantee a single writer.

Exclusive Lock Acquisition

A participant node uses a write connection pool that is tied to an exclusive lock on a main connection, and a shared lock on all pool connections. If the main lock is lost, the pool's connections are ramped down. The new active node must wait until all the passive node's pool connections are closed, which is done by trying to acquire the shared lock in exclusive mode.

Note: Using the same connection for writes ensures that the lock is active while writes are performed.

Lock ID Allocation

Exclusive application-level locks are identified by a 30-bit integer lock ID which is allocated based on a scope name and counter.

The lock counter differentiates locks used in Canton from each other, depending on their usage. The scope name ensures the uniqueness of the lock ID for a given lock counter. The allocation process generates a unique lock ID by hashing and truncating the scope and counter to 30 bits.

Note: On Oracle, the lock scope is the schema name, i.e. user name. On PostgreSQL, it is the name of the database.

Participant nodes must allocate lock IDs and counters consistently. It is, therefore, crucial that nodes are configured with the same storage configuration, e.g. for Oracle using the correct username to allocate the lock IDs within the correct scope.

25.1.2.3 Prevent Passive Node Replica Activity

Important: A passive node replica does not hold the exclusive lock and cannot write to the shared database.

To avoid passive node replicas attempting to write to the database - any such attempt fails and produces an error - we use a coarse-grained guard on sync domain connectivity and API services.

To prevent the passive node from processing sync domain events, and ensure it rejects incoming Ledger API requests, we keep the passive node disconnected from the sync domains as coarse-grained enforcement.

Lock Loss and Failover

If the active node crashes or loses connection to the database, the lock is released and a passive node can claim the lock and become active. Any pending writes in the formerly active node fail due to losing the underlying connection and the corresponding lock.

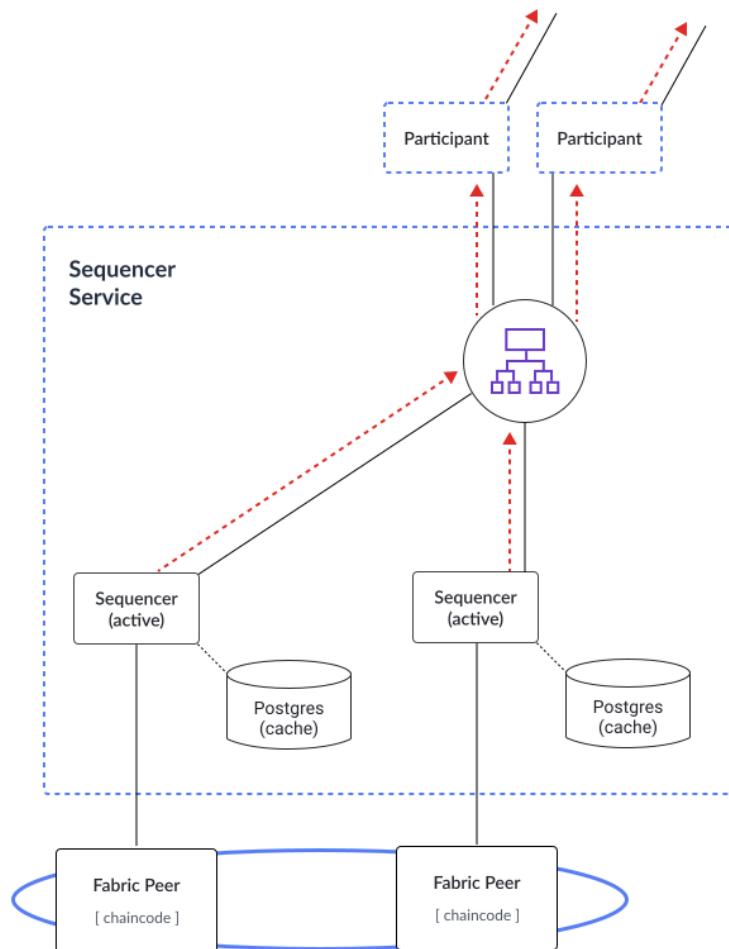

The active node has a grace period in which it may rebuild the connection and reclaim the lock, due to the higher frequency of health checks on the lock in the active node vs. the passive node trying to acquire the lock at a lower frequency.

The passive node continuously attempts to acquire the lock within a configurable interval. Once the lock is acquired, the participant node's replication manager sets the state of the successful node to active.

When a passive node becomes active, it connects to previously connected sync domains to resume event processing. The new active node accepts incoming requests, e.g. on the Ledger API which starts when the node becomes active. The former active node, which is now passive, shuts down its Ledger API to stop accepting incoming requests.

25.1.3 HA on the Synchronization Domain

The diagram shows a sync domain containing the topology manager, mediator, and sequencer components.

A sync domain is fully available only when all components are available. However, transaction processing still runs even when only the mediator and the sequencer are available.

As all of the sync domain components run in separate processes, HA is architected per component. This means that in an HA deployment, the sync domain is not deployed as a node (which would run the mediator, sequencer, and manager in a single process).

25.1.3.1 Sequencer

Sequencer HA depends on the chosen implementation. For example, when using a ledger such as [Hyperledger Fabric](#), HA is already set up. Multiple sequencer nodes must be deployed.

The sync domain exposes multiple sequencer endpoints, any of which can be used to submit sequencing requests or read events.

Database Sequencer

The database sequencer has an active-active setup over a shared database.

The sequencer relies on the database for both HA and consistency. The database ensures that events are sequenced in a consistent order.

Many sequencer nodes can be deployed. Each node has concurrent read and write components when accessing the database. The load balancer evenly distributes requests between sequencer nodes.

Note: The system stops sending requests to an unhealthy node.

Consistency and the Database Sequencer

Each node is assigned a distinct index from the total number of sequencer nodes. The index is included in event timestamps to ensure that sequencer nodes never use duplicate event IDs/timestamps.

Events are written to the `events` table in ascending timestamp order. Readers need to know the point at which events can be read without the risk of an earlier event being inserted by a write process. To do this, writers regularly update a `watermark` table into which they publish their latest event timestamp. Readers take the minimum timestamp from the table as the point from which they can safely query events.

Failing Sequencer Nodes and the Database Sequencer

If a sequencer node fails, it stops updating its `watermark` value and, when the value reaches the minimum timestamp, all readers pause as they cannot read beyond this point.

When sequencer writers update their `watermark`, they also check that other sequencer watermarks are updated promptly. If a sequencer node has not updated its watermark within a configurable interval, it is marked as offline and the watermark is no longer included in the query for the minimum event timestamp. Future events from the offline sequencer are ignored after this timestamp.

Note: For this process to operate optimally, the clocks of the hosts of the sequencer nodes should be synchronized. This is considered reasonable for co-located sequencer hosts which use NTP.

Recovering Sequencer Nodes

When a failed sequencer recovers and resumes operation, it deletes all events that arrived past its last known watermark. This avoids incorrectly re-inserting them, as readers may have seen them already.

It is safe to do this and it does not affect events that have already been read. Any events written by the sequencer while it is offline are ignored by readers. The sequencer then replaces its old watermark with a new timestamp and resumes normal operation.

After resuming operation, there is a short pause in reading from other sequencers due to updates to the watermark table. However, requests to the other sequencer nodes continue successfully, and any events written during this period are available for reading as soon as the pause is over.

The recovered sequencer has likely lost any send requests that were in process during failure. These can be safely retried, without the risk of creating duplicate events, once their `max-sequencing-time` is exceeded.

25.1.3.2 Mediator

Like the [participant node](#), the mediator is replicated and only one replica node is active.

All replicas of the same mediator node share the same database to access the state and coordinate with the active mediator node.

25.2 HA for Production Systems

This section covers how to implement High Availability (HA) in production systems.

25.2.1 HA and Horizontal Scaling

25.2.1.1 Introduction

This section describes how to deploy a complete Daml solution in an HA configuration with horizontal scaling characteristics.

The distributed solution uses Daml v2.x Enterprise with Canton services, HTTP JSON API server, Trigger services (deprecated), and OAuth 2.0 middleware components. In this document we primarily discuss a SQL sync domain that uses PostgreSQL as the synchronization mechanism for the sequencer backend. We also describe a blockchain synchronizer.

Information in this section is useful for the following:

- Production deployment planning.
- Understanding HA architectures.
- Understanding Daml application scalability.
- Building Kubernetes deployments.
- HA/scalability deployments in the cloud or on-premises.

Target audience

1. A distributed application provider who runs a sync domain and their own participant service.
2. Distributed application users who run a participant service.
3. Infrastructure operators or site reliability engineers (SREs).

Important: A distributed application build engineer persona acts as a combination of all three target audiences as they need to validate that the distributed application works as part of the CI/CD activity.

25.2.2 High Availability From a Business Perspective

Important: This section contains information for those unfamiliar with HA and how it is fundamental to operational efficiency. We look at how business goals drive the configuration and operational aspects of the HA deployment.

Those familiar with these principles may skip this page.

Definition¹

High availability (HA) is a characteristic of a system which aims to ensure an agreed level of operational performance, usually [uptime](#), for a higher than normal period.

There are three principles of [systems design](#) in [reliability engineering](#) which can help achieve high availability.

¹ https://en.wikipedia.org/wiki/High_availability as retrieved 02/22/2023

1. Elimination of [single points of failure](#). This means adding or building redundancy into the system so that failure of a component does not mean failure of the entire system.
2. Reliable crossover. In [redundant systems](#), the crossover point itself tends to become a single point of failure. Reliable systems must provide for reliable crossover.
3. Detection of failures as they occur. If the two principles above are observed, then a user may never see a failure - but the maintenance activity must.

Daml solution design honors these principles by:

1. Eliminating single points of failure through redundant components.
2. Executing reliable crossover through networking best practices, in conjunction with the Canton transaction consensus protocol, to eliminate partially processed requests.
3. Ensuring automated failover when a single failure is detected.

[Multi-Region fundamental 1: Understanding the requirements.](#)
[Availability Table.](#)
[Embracing Risk.](#)
[What is an error budget—and why does it matter?.](#)
[Available or not? That is the question—CRE life lessons.](#)

25.2.2.1 Availability

Availability defines whether a system is able to fulfill its intended function over a period of time, i.e. the system works as intended 99.5% or 99.999% of the time.

The inverse is the percentage of time it is expected to fail, such as 0.5% or 0.001%.

Time-based availability

Availability is usually measured in whole system uptime percentage, rather than the uptime percentages of separate components.

A refinement of this metric is *unplanned downtime*, i.e. the amount of time that the system is unexpectedly unavailable. This is because well-published maintenance activities have no business impact whereas unplanned downtime can cause lost revenue, reputational harm, customers switching to a competitor, etc.

The general formula is:

$$availability = uptime / (uptime + downtime)$$

This formula calculates how many minutes of downtime are allowed in a given period. For example, a system with an availability target of 99.99% can be down for up to 52.56 minutes in an entire year and stay within its availability level.

The table below shows estimated downtimes for a number of given availability levels.

Avail-ability level	Down-time per year	Down-time per quarter	Down-time per month	Down-time per week	Downtime per day Downtime per hour	
90%	36.52 days	9.13 days	3.04 days	16.80 hours	2.40 hours 6.00 minutes	
95%	18.26 days	4.57 days	1.52 days	8.40 hours	1.20 hours	3.00 minutes
99%	3.65 days	21.91 hours	7.30 hours	1.68 hours	14.40 minutes	36.00 seconds
99.5%	1.83 days	10.96 hours	3.65 hours	50.40 minutes	7.20 minutes	18.00 seconds
99.9%	8.77 hours	2.19 hours	43.83 minutes	10.08 minutes	1.44 minutes	3.60 seconds
99.95%	4.38 hours	1.10 hours	21.91 minutes	5.04 minutes	43.20 seconds	1.80 seconds
99.99%	52.59 minutes	13.15 minutes	4.38 minutes	1.01 minutes	8.64 seconds	0.36 seconds
99.999%	5.26 minutes	1.31 minutes	26.30 seconds	6.05 seconds	0.86 seconds	0.04 seconds

Note: For a custom availability percentage, use the [availability calculator](#).

Data like this helps a business define an error budget or the maximum amount of time that a technical system can fail without contractual consequences. ² which may also be a KPI for SREs.

For example, over a 30 day (43,200 minutes) time-window, with an availability target of 99.9%, the system must not be down for more than 43.2 minutes. This 43.2 minute figure is a concrete target to plan around, and is often referred to as the error budget. If you exceed 43.2 minutes of downtime over 30 days, you fail to meet your availability goal.

Aggregate request availability

In contrast to time-based availability, the fine-grained aggregate request availability metric considers the number of failed requests i.e. x% of total failed requests.

This metric is most useful for services that may be partially available or whose load varies over the course of a day or week rather than remaining constant, or to monitor specific, business-critical endpoints.

The general formula is:

$$availability = \frac{successfulRequests}{totalRequests}$$

Although not all requests have equal business value, this metric is often calculated over all requests made to the system. For example, a system that serves 2.5M requests per day, with a daily availability target of 99.99%, can serve up to 250 errors and still hit the target.

² <https://www.atlassian.com/incident-management/kpis/error-budget>

Note: If a failing request retries and succeeds, it is not considered failed since the end-user sees no failure.

25.2.2.2 Resiliency

Resiliency is related to availability. Resiliency is the capability to handle partial failures while continuing to execute and not crash. In modern application architectures – whether it be microservices running in containers on-premises or applications running in the cloud – failures are going to occur. For example, applications that communicate over networks (like services talking to a database or an API) are subject to transient failures. These temporary faults cause lesser amounts of downtime due to timeouts, overloaded resources, networking hiccups, and other problems that come and go and are hard to reproduce. These failures are usually self-correcting. ³

Resiliency and availability are enhanced by best practice patterns, such as the retry pattern. When a customer submits a request and receives a success response, they expect that request to succeed. If they receive an error response instead, then the user does not expect it to succeed and knows that they need to retry the request.

Retries can be an effective way to handle transient failures that occur with cross-component communication in a system. [?] A retry pattern is often coupled with the circuit breaker pattern, which effectively shuts down all retries on an operation after a set number of retries have failed. This allows the system to recover from failed retries after hitting a known limit and gives it a chance to react in another way, like falling back to a cached value or returning a message to the user to try again later. [?]

The Daml solution's client application needs to add this type of resiliency to increase availability of the overall system consisting of platform and application.

25.2.2.3 Other Common Metrics / RTO and RPO

Recovery Time Objective (RTO) is the maximum acceptable delay between the interruption of service and restoration of service. This value determines an acceptable duration over which the service is impaired. It is a slice of the error budget but for a single instance of downtime.

Recovery Point Objective (RPO) is the maximum acceptable amount of time since the last data recovery point. This determines the acceptable data loss between the latest recovery point and a service interruption.

Financial systems often require support for an RPO of zero.

³ <https://azure.microsoft.com/en-us/blog/using-the-retry-pattern-to-make-your-cloud-application-more-resilient/>

25.2.2.4 HA Cost Trade-Offs

High availability can be costly and thus require trade-offs.

To illustrate, extreme events that are highly improbable and costly to guard against - such as an asteroid strike that wipes out a continent's data centers - may not need consideration. This highlights the trade-off between the cost of avoiding an outage, the probability of a single failure (single component redundancy), and the probability of multiple simultaneous failures (multiple component, integrated redundancy).

We can analyze the trade-offs by deriving the cost of loss of availability using unplanned downtime as follows:

$$\text{cost} = \text{errorBudget} * \text{revenueLostPerMinuteOfDowntime}$$

where the revenue lost per minute of downtime is a projected or measured statistic.

Use this formula in different configurations to compare increasing cost against availability to determine an appropriate trade-off for your business goals.

25.2.3 Use Cases By Role

25.2.3.1 Distributed Application Provider

The distributed application provider is also the sync domain owner and the sync domain administrator. Their deployment activities come first since all other activities require a sync domain.

Deploy a synchronization domain

The distributed application provider deploys the following components:

- The sync domain manager.

- The mediator.

- The sequencer.

- The HA-configured PostgreSQL managed service¹ that is the sequencer's backend.

¹ The PostgreSQL managed service could also be a PostgreSQL server running on hardware that was deployed by the user.

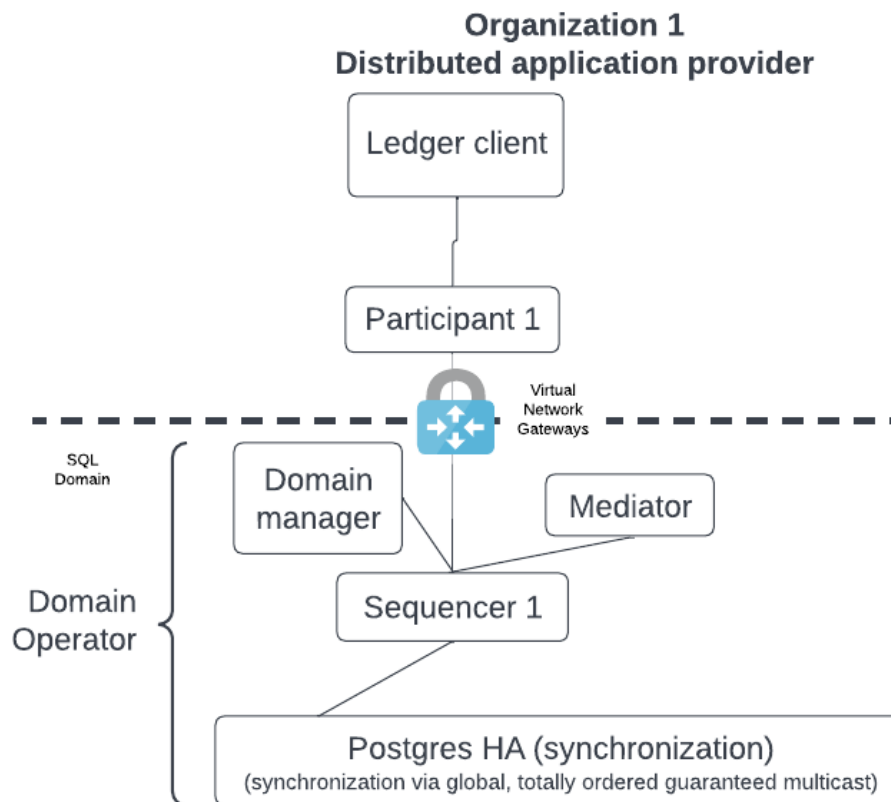

**Note:**

The sync domain manager, mediator, and sequencer all have internal databases - not shown here - which should be HA-configured.

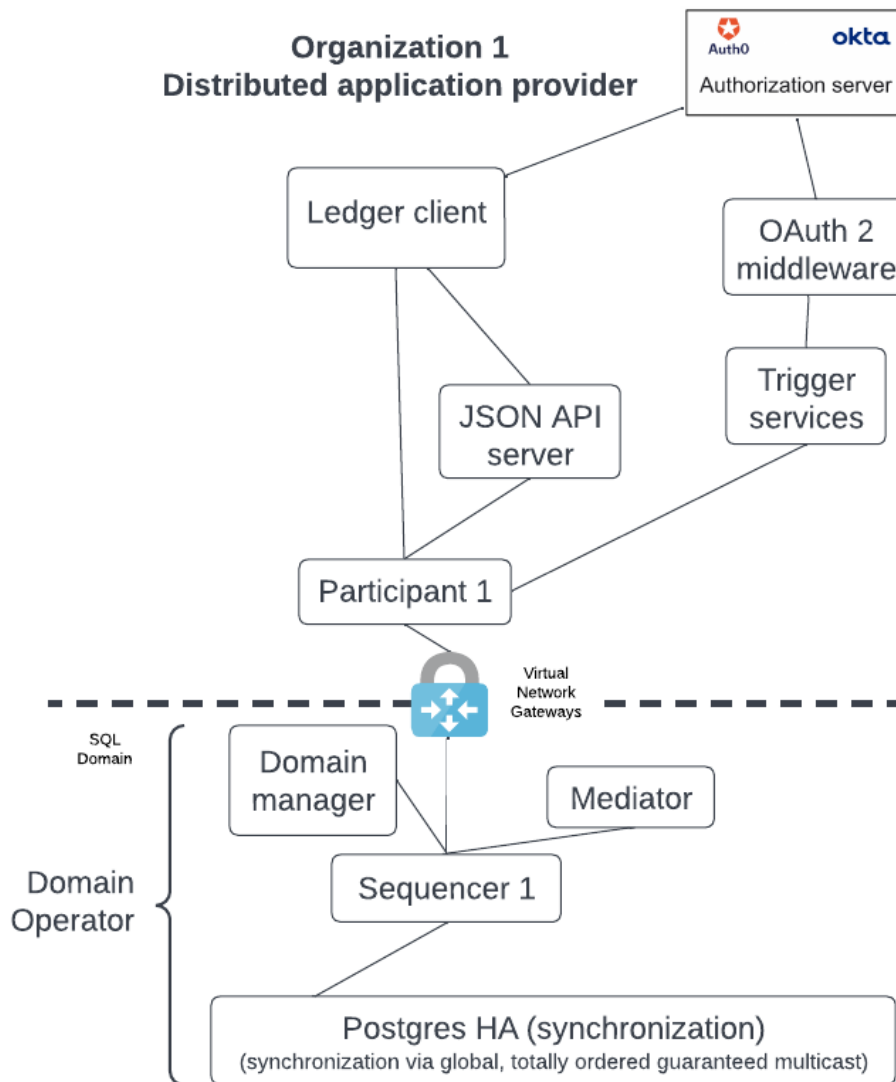

Also not shown, a bastion host (e.g. [Azure bastion host](#)) can be configured for accessing the sync domain components. This provides an additional layer of security by limiting access to the sync domain. Additional production access controls may be needed.

The distributed application provider may choose to isolate the sync domain from their participant node as a security measure using a Virtual Network Gateway as shown. If this additional isolation is not required then the Virtual Network Gateway is not needed. A different type of networking component may be more appropriate - e.g. HAProxy, NGINX, etc.

The figure below shows the participant node and its ledger client.

As mentioned, the distributed sync domain owner can add additional components which interact with the participant node. These components are normally deployed shortly after deploying the participant node.

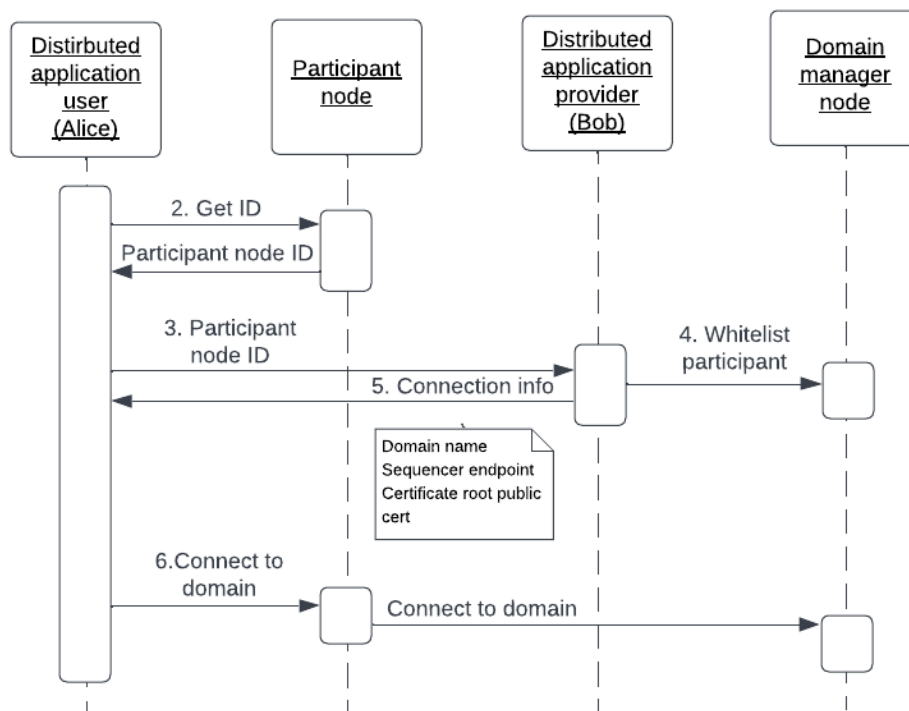

Connect a new participant node

We expect the sync domain to run in permissioned mode with allow-listing² enabled to only include participant nodes whose identities have been registered with the sync domain manager. This involves a data exchange between the distributed application provider and the distributed application user.

The distributed application provider communicates specific information to a new distributed application user so that the user's participant node can join the application's sync domain. The figure below illustrates this exchange, with **Bob** as the application provider and **Alice** as the new application user.

² The default mode is an open mode which is less secure.

1. Alice deploys a participant node - not shown.
2. Alice extracts the participant node's unique identifier into a string. The ID includes the display name for the participant plus a hash of the public identity signing key.
3. Alice makes her participant ID known to Bob through an external mechanism, e.g. email.
4. Bob runs a console command which adds Alice's participant ID to the sync domain allowlist and configures the appropriate node's permissions. An example command which gives default permissions is shown here:

```
domainManager1.participants.set_state(participantIdFromString, □
↳ ParticipantPermission.Submission, TrustLevel.Ordinary)
```

5. **Bob passes Alice the following information, which allows her to connect to the sync domain:**

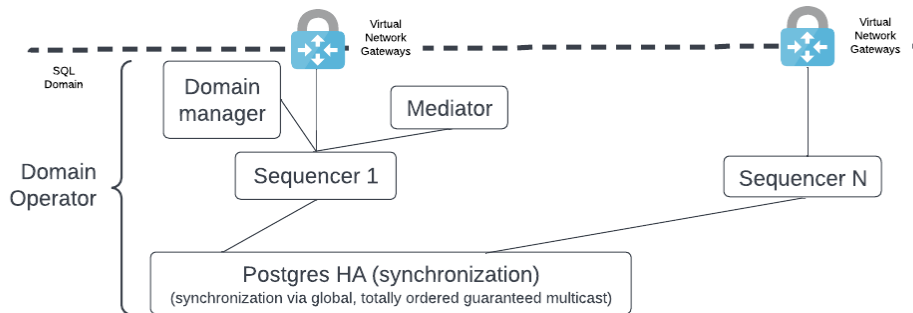

- a. One, or more, sequencer endpoints - https URLs.
- b. Certificate root public cert, if it's not a publicly signed CA.
6. Alice picks a unique name for the synchronizer that is local to her participant. This will be used in the connection command.
7. Alice enters the information into the connection command `connect_multi` and connects to Bob's synchronizer - not shown.

```
participantAlise.domains.connect_multi("AliceDomainName", Seq(sequencer1, □
↳ sequencer2))
```

Prepare synchronization domain infrastructure for adding new participant nodes

A distributed application provider expands the use of their application by allowing more participant nodes to join their sync domain. A sequencer node is the gateway to the sync domain for all participant nodes. It follows that the policy on when to add a new sequencer is important and must be clearly defined.

As shown below, a sync domain may start with a sequencer node and then add more sequencer nodes as required.

There are two options for adding a new participant node.

1. Deploy a sequencer for each participant node to introduce more isolation between the events each participant sees. For example, Coke may want to avoid cross-contamination of events with Pepsi, and vice-versa, so each organization wants its own sequencer. The Coke sequencer sees all the Coke and Pepsi messages through the shared database; the sequencer backend is a broadcast. However, Coke's sequencer node provides a multicast to Coke's participant node with only Coke's events. Pepsi's setup functions similarly.
2. Avoid the additional isolation and focus on high resource utilization of the sequencer by having several participant nodes use the same sequencer; i.e. a single sequencer handles multiple distributed application users. This option produces a lighter load on the joint HA PostgreSQL database.

25.2.3.2 Distributed Application User

The distributed application user deploys their own participant node and connects to the provider's public sequencer endpoint. There is some similarity here with the distributed application provider. However, the distributed application user's DAR files (i.e. business logic) may be a subset of the DAR files deployed by the distributed application provider.

This setup is extendable. For example, the distributed application user may be interested in several distributed applications, and so connect their participant node to the related sync domains by deploying multiple DARs for the different applications' business logic. They may also write their own extensions that include additional DARs. These extensions do not impact the use cases described here.

The simple configuration shown above, like that of the sync domain owner, can expand into a more capable deployment such as shown below by adding the HTTP JSON API server, trigger services (deprecated), and OAuth2 middleware.

Upload the distributed application DAR files

Check the documentation for information on how to [upload DAR files](#).

25.2.3.3 Site Reliability Engineer (SRE)

Monitor systems

The SRE's primary use case is monitoring. Monitoring is required on both the sync domain and participant nodes, although the scope is slightly different.

Monitoring normally consists of the following activities:

- Export logs.
- Expose metrics via Prometheus endpoint.
- Parse out trace IDs from the log files.
- Keep logs for audit.

Check the documentation for more information on [monitoring](#).

25.2.4 Implementing HA and Scaling Deployments

25.2.4.1 Basic Daml Deployment

The diagram below illustrates the most basic multi-party Daml deployment possible.

Each logical box in the diagram contains multiple internal components in an HA production configuration. The following sections expand on each of these logical boxes to show how they are configured for production.

The diagram shows the following components:

A **Ledger client** that uses the Ledger API; the client entry point to execute business logic.

Participant nodes which expose the public Ledger API. They execute the Daml business logic of the distributed application based on an API request or as part of the Canton transaction consensus protocol.

A **Mediator** which acts as a transaction manager for the Canton consensus protocol. Ensures that either all of the parts of a transaction succeed or there is no change.

The **Sync domain manager** which manages the sync domain with transactions that update the topology and make public keys available.

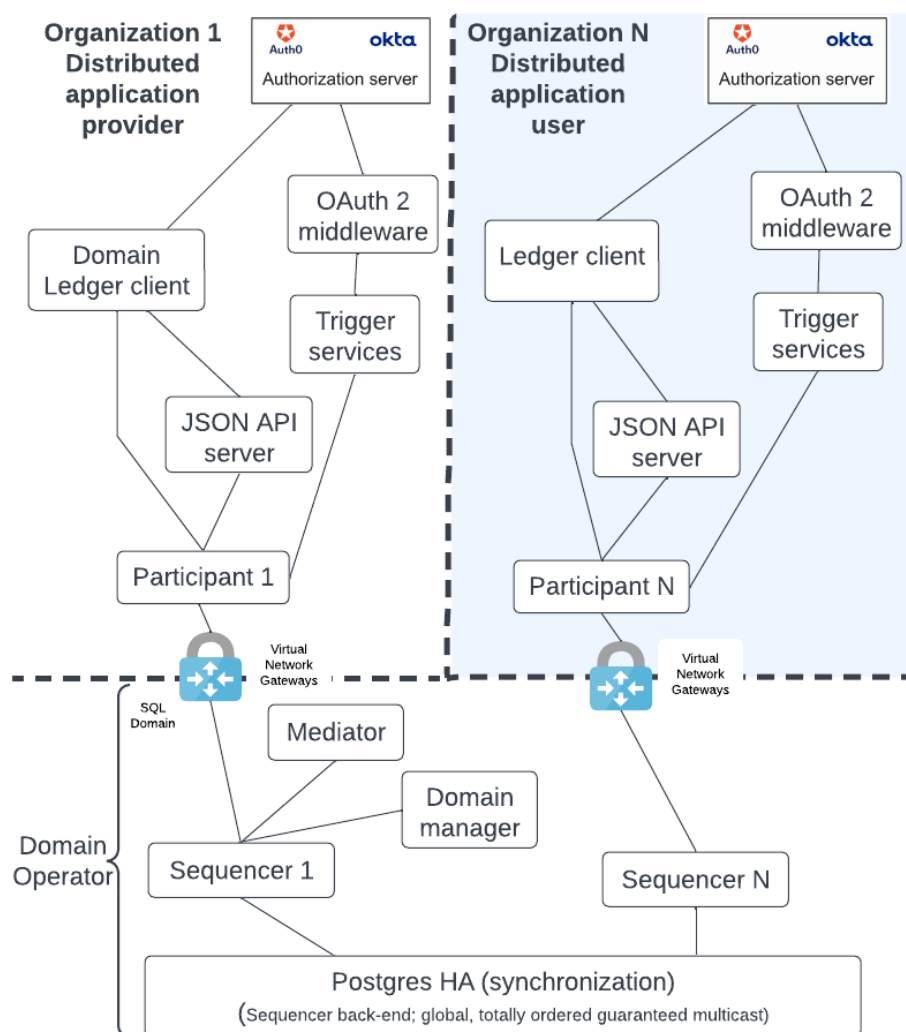

Sequencers expose the Canton API so that all clients see events as ordered by a guaranteed, multicast communication mechanism. A sequencer has a backend component that is hidden from its clients. Depending on the backend component, the solution supports either a SQL or blockchain sync domain.

Note: The term **node** may refer to a logical box with multiple components or a single JVM process depending on context.

The distributed application **provider** deploys several components: the sync domain (sync domain manager¹, mediator, and sequencer) and their own participant node(s).

The distributed application **user** only has to deploy a participant node and connect that node (from their own private network) to the private network of the sync domain via communication with a sequencer.²

A typical Daml deployment has additional components which are shown in the figure below:

The diagram shows the following components:

¹ The sync domain manager can also be referred to as the 'topology manager'. For a production deployment, the sync domain manager can be thought of as containing the topology manager with some additional capabilities.

² Although there are multiple sequencers shown, this is just for illustration purpose. As little as a single sequencer is needed. For example, Organization N's participant node could connect to Sequencer 1 and not Sequencer N.

An HTTP **JSON API server** which supplements the gRPC API endpoints of the participant node by providing an HTTP REST (HTTP JSON API) endpoint. It also has an internal cache so that it can be more responsive to queries.

Trigger services (deprecated) that listen to the ledger event stream for events that trigger business logic.

OAuth2 middleware that supports a refresh of the Trigger services JWT token and manages the background requests for a refresh token for the Trigger services.

The *Identity Provider (IDP)* is the authentication entity that provides the JWT token. The IDP is outside of the Daml solution but nevertheless a necessary component. Different organizations may use different IDPs for their participant nodes.

Note: We expect the sync domain owner to implement additional business logic for managing the distributed application in both their participant node and trigger service nodes.

25.2.4.2 Architecture for HA and Scaling

As a production system becomes busier, it is necessary to scale up the components.

Vertical scaling is the easiest way to handle more load, but there are limits to its benefits. Vertical scaling is not discussed here since this is a well-known technique. Instead, this document focuses on horizontal scaling where backup/redundant components are deployed to different availability zones as part of the HA configuration.

Note: For clarity the diagrams follow these conventions:

Solid, black boxes for individual instances, processes, and containers.

Databases may be identified as shared and highly available with an **HA** in the disk figure.

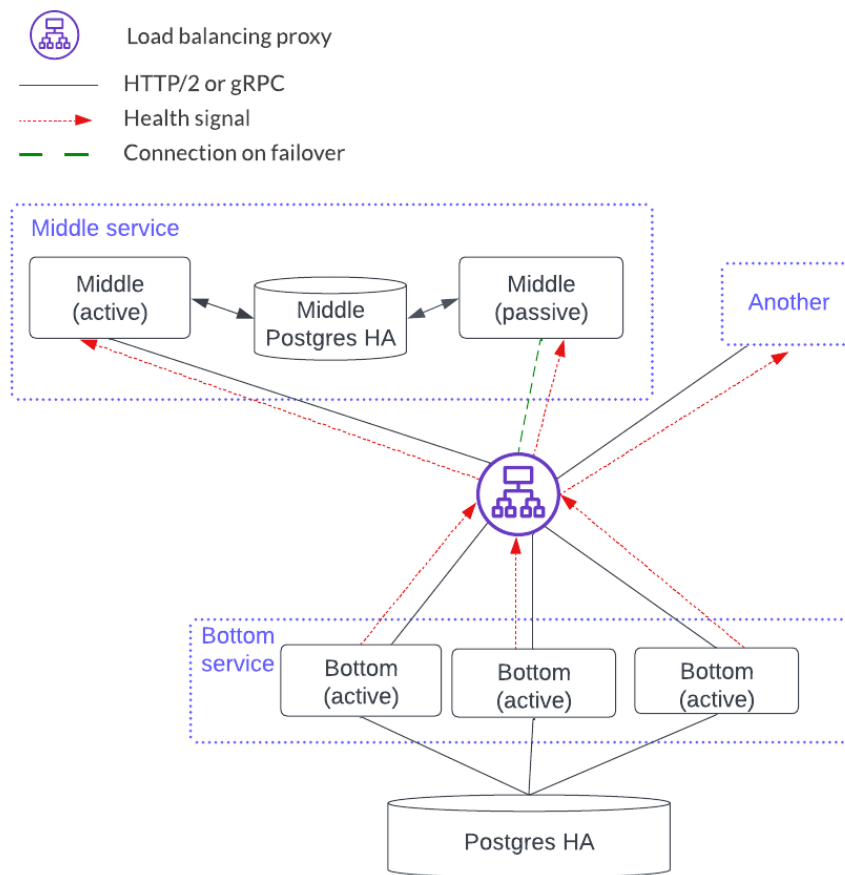

Distinguishing between a single instance and the HA variant is done by using the term **service** for HA. There is also a blue dashed line around the components that make up an HA service. The word **service** is chosen because it looks like a single endpoint which is highly available, like a managed service in the cloud.

For simplicity, a blue dashed box with a name is shorthand for the HA variant of that component.

Health signals are a dashed red line that point to the instance that is a recipient of that signal.

Communication channels that are passive but become active upon failover are bordered by a dashed green line.

Thus, in the figure below, the **Middle service** blue box encompasses all the components that make up that service. Middle services instances are in black boxes with solid lines. The blue box **Another** is short form for a service called Another. There is a load balancer between the middle and bottom services.

Each component can scale using a stateless or stateful horizontal scaling pattern. In this diagram, the bottom service has instances that are independent and considered stateless. Stateless horizontal scaling is achieved by adding another bottom instance. This also increases the availability because there are more redundant instances. The middle service is stateful since the instances share a local database so the HA model is active-passive. Scaling the stateful middle service is achieved by replicating the entire middle service: i.e. add two instances connected by a PostgreSQL HA database.

25.2.4.3 HTTP JSON API and Participant Node Services

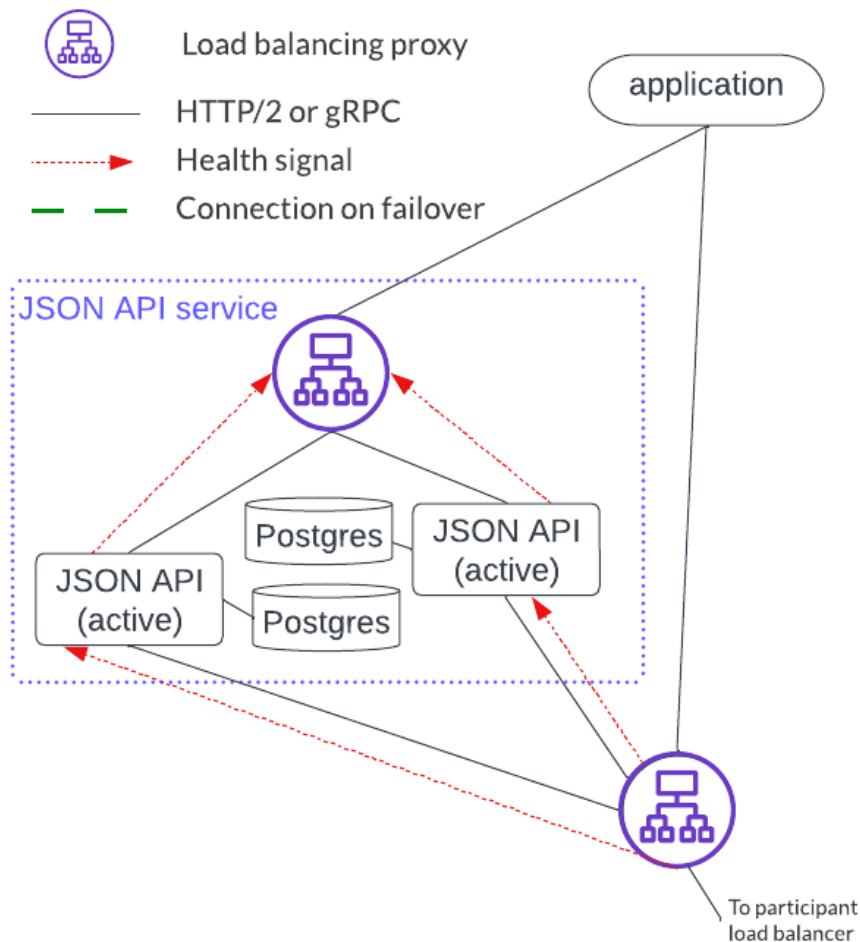

In cases where there is a single participant service (and corresponding HTTP JSON API service) that all the client requests go to, the HTTP JSON API and participant services need to be considered together since there are some state dependencies between the two. In particular, users and related parties are configured on a participant node so they will be handled by a particular participant service. This means that the HTTP JSON API service that is connected to a participant service also serves those same users and parties.

However, if there is more than one participant service (e.g. with horizontal scaling) then it is the application's responsibility to understand which participant service to send a request to (and the corresponding HTTP JSON API service), based on the user(s) or parties of the request. Another way to describe this is that users and parties are sharded across the participant and HTTP JSON API services and the application is responsible for targeting the right instance.

As shown below, an HTTP JSON API service is an endpoint that has four components. Each HTTP JSON

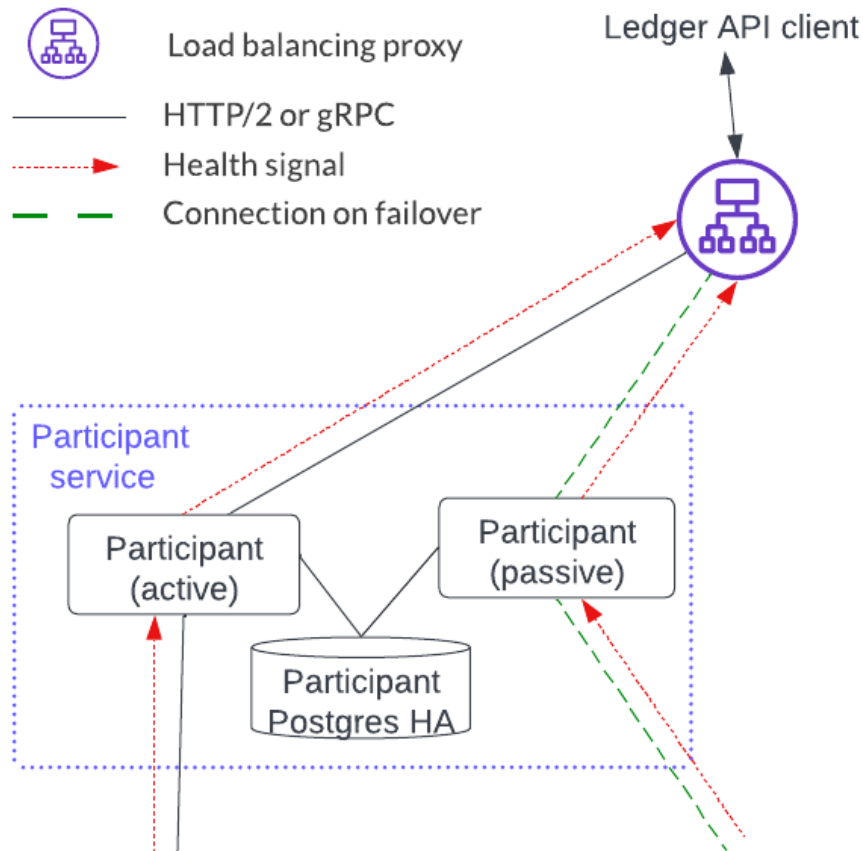

API instance emits a health signal that the load balancer uses to direct traffic. The HTTP JSON API's database acts as a cache that is local to the instance, meaning it does not need to be HA since the cache can be reconstructed at any time.

Note: The HTTP JSON API server does not currently support mTLS from client applications. mTLS is supported between the load balancer and participant node.

There are a couple of important distinctions between the participant service and the HTTP JSON API service setup:

A single participant service can have several HTTP JSON API servers. However, a given HTTP JSON API server should only connect to a single participant service. The HTTP JSON API component operates in an active-active mode while participant nodes operate in an active-passive mode.

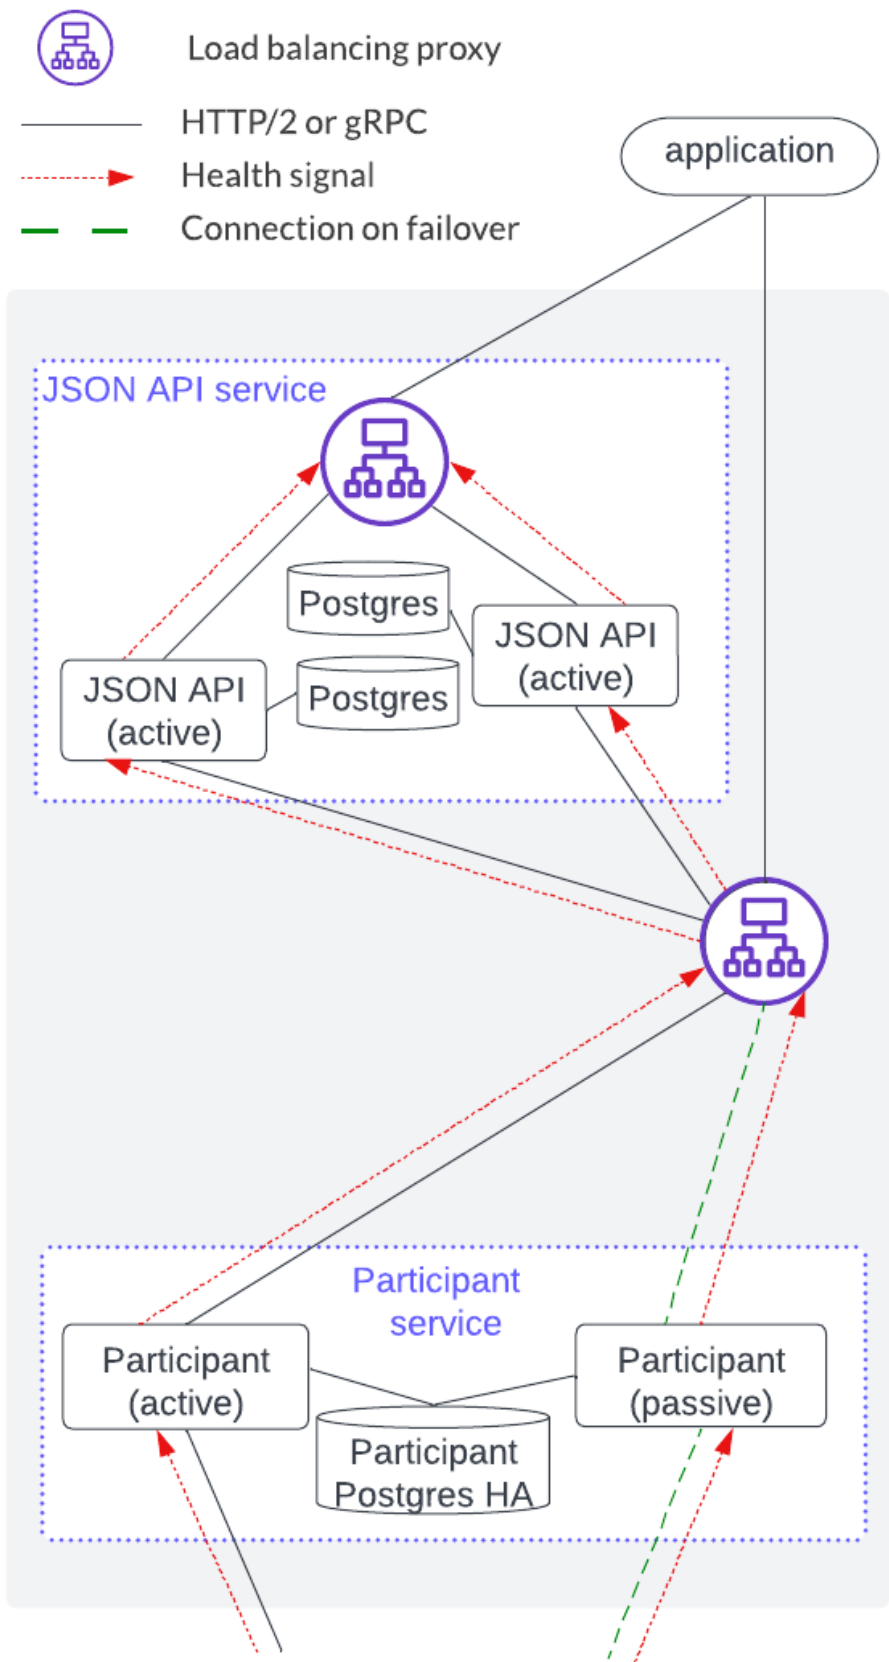

The deployment below shows a single HTTP JSON API service and participant service. There are some hidden state dependencies that include:

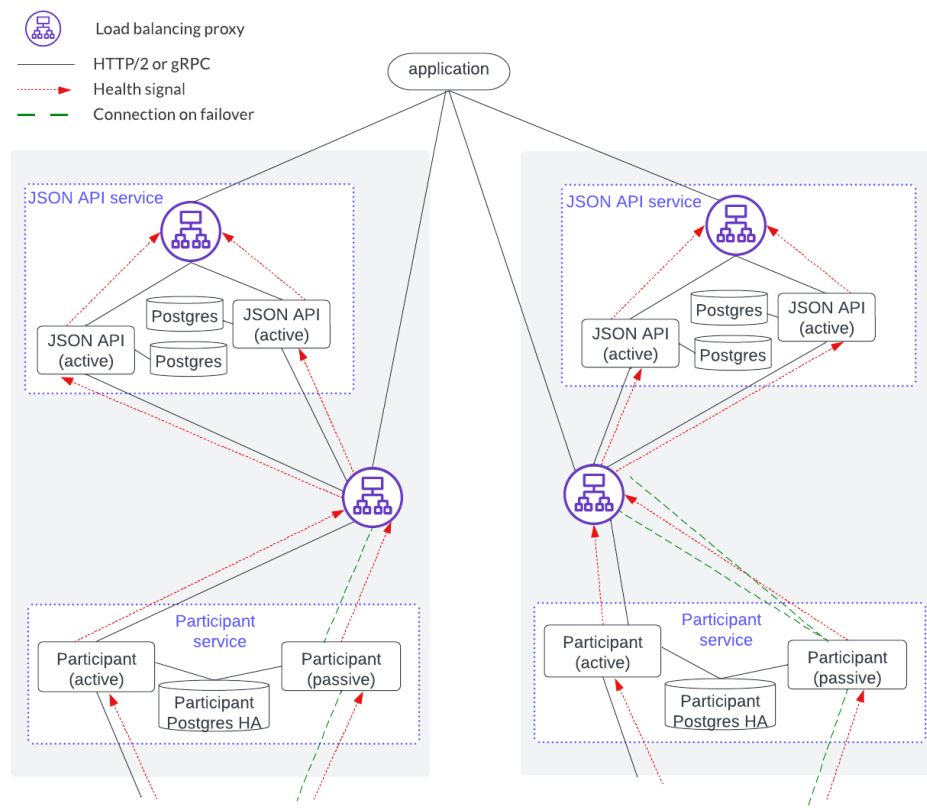

A ledger offset that requires the HTTP JSON API server to be associated with a single participant service.

[Command deduplication](#) functions on a single participant service alone.

Shared users and parties for both the HTTP JSON API service and the participant service.

Horizontal scaling is accomplished by sharding application users and parties across a joint HTTP JSON API and participant service, and adding another HTTP JSON API and participant stack, as shown below.

25.2.4.4 Sequencer Service

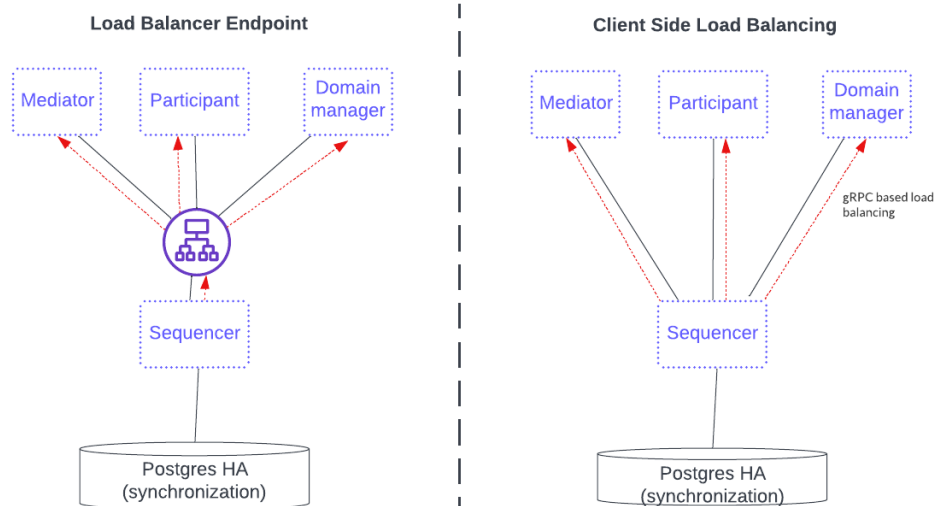

The sequencer service operates in active-active mode, which means that all sequencer instances can accept and process Canton protocol API requests. This has benefits for both scaling and availability.

Deploying a sequencer depends on business requirements which may impact deployment configurations such as load balancing configurations and whether the sync domain is fully or only partially decentralized.

Sequencer service load balancing options

The sequencer service has several clients: participant, mediator, and sync domain manager. mTLS between these clients is unavailable at the time of writing.

The two available load-balancing options are shown in the diagram below.

The first option, on the left, fronts the sequencer service with a load balancer that all sequencer clients use. This option simplifies configuration and connectivity but adds the complexity of configuring the load balancer.

The option on the right is a gRPC java client library providing a round-robin selection mechanism for load balancing that automatically round-robins through multiple sequencer connections and includes the healthy ones. This setup requires the distributed application provider and distributed application users to maintain the configuration information of all the available sequencers in the sequencer client. The sequencer client continuously monitors the health of each sequencer endpoint when selecting a possible node in a round-robin fashion.

See the Canton documentation on [connection to high availability sequencers](#) and [client load balancing](#) for more information.

Blockchain synchronization domains

A blockchain sync domain has a fully decentralized data path and is used when there is no trust between the distributed application providers and users. Whereas the sequencer queries the PostgreSQL backend directly in a SQL sync domain, this cannot be done in a blockchain sync domain. Instead, a local database to the sequencer is added to speed things up. The sequencer backend then uses the blockchain to provide a guaranteed ordered multicast of events.

The figure below shows a HyperLedger Fabric blockchain example. Notice that each sequencer has an independent local cache running on a PostgreSQL database. This local cache ensures efficiency because the sequencer avoids having to scan the entire blockchain when it starts up or reconnects after a temporary interruption. It also reduces the performance load on the blockchain.

This figure has a load balancer fronting the sequencer nodes, but client-side load balancing would also work. There are several benefits to using a load balancer:

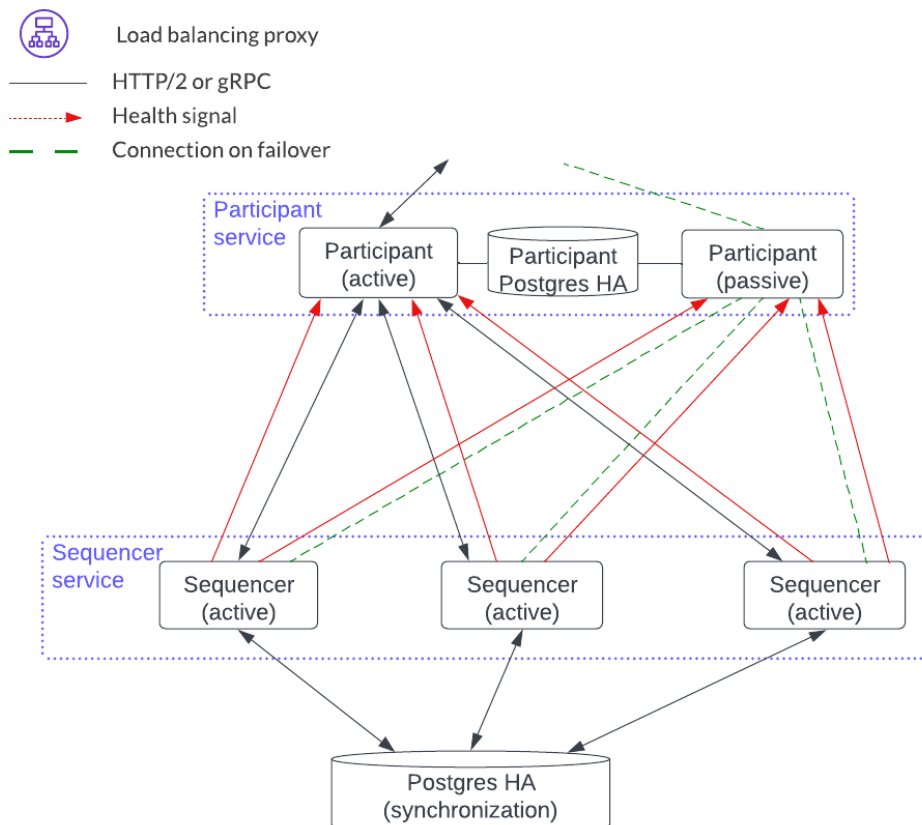

- Clients have a single endpoint that consolidates the health signals, simplifying setup and troubleshooting.
- Adding a sequencer does not require updating the configuration information in each client.
- Additional security.

Since sequencer nodes are always active, horizontal scaling for a blockchain sequencer service is achieved by adding a new sequencer along with its associated local cache database and enabling it for client use.

SQL synchronization domains

The SQL sync domain is only partially decentralized and is used when the sequencer's backend data is stored in a single PostgreSQL database managed by a centralized distributed application provider. This option requires participant users to have some trust in the application provider.

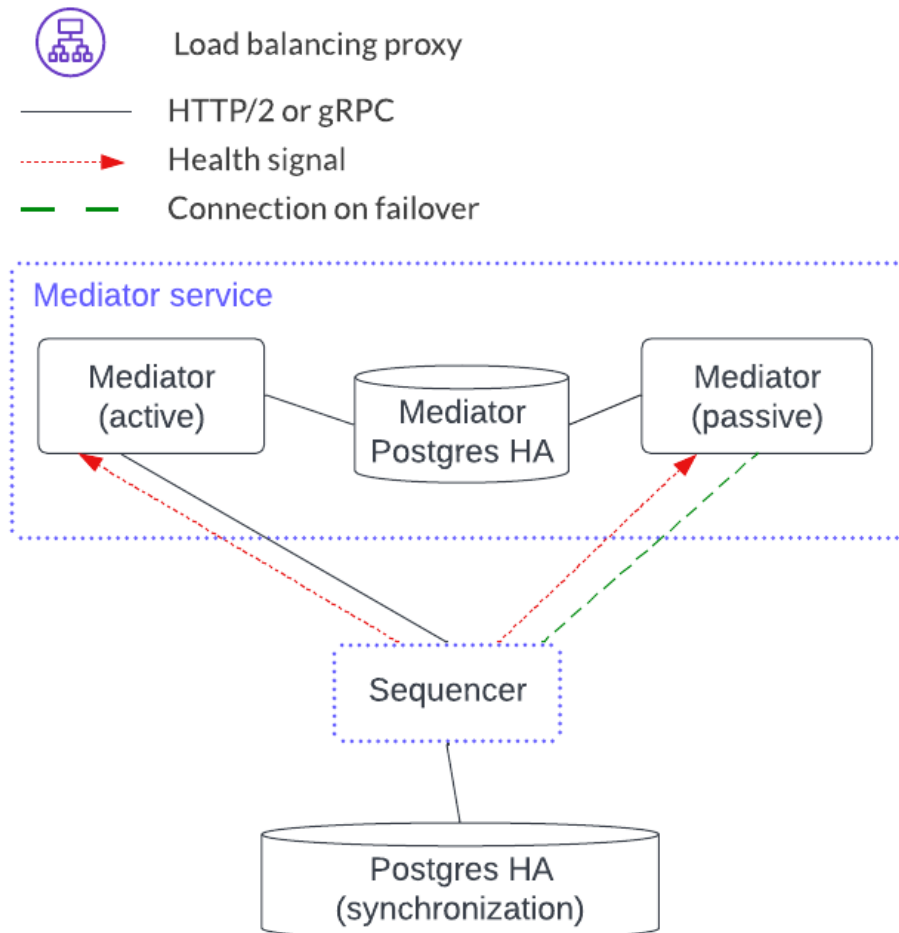

A sequencer needs no local cache because it queries the backend database directly with no performance penalty.

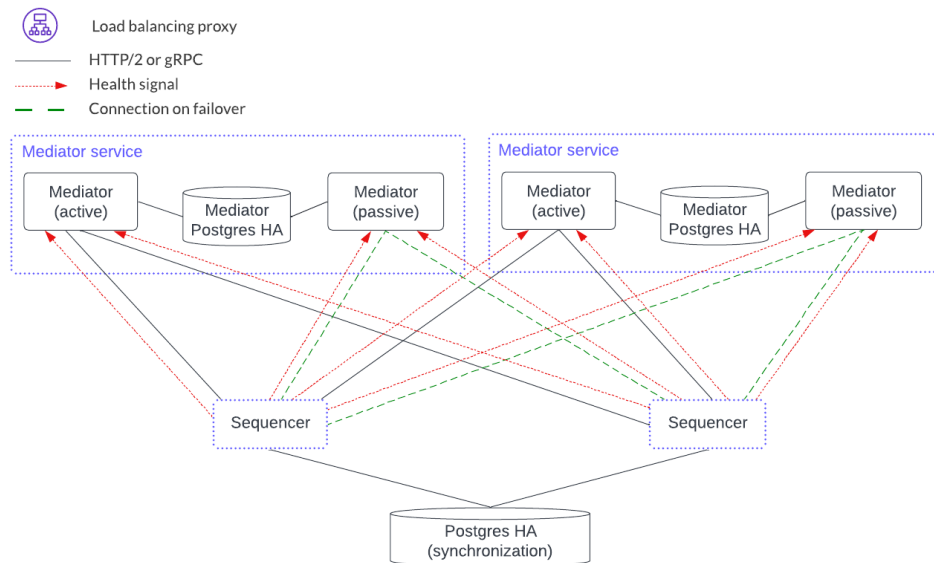

Since sequencer nodes are always active, horizontal scaling for the SQL sync domain sequencer service is achieved by adding a new sequencer and enabling the clients to use it.

25.2.4.5 Mediator Service

The mediator service has no client-facing ingest. It also has no load-balancing proxy or health endpoints. Instead, it uses client-side load balancing based on the gRPC infrastructure. It is like the participant node in that it has a PostgreSQL database in an HA configuration. The mediator components, however, act in an active-passive configuration.

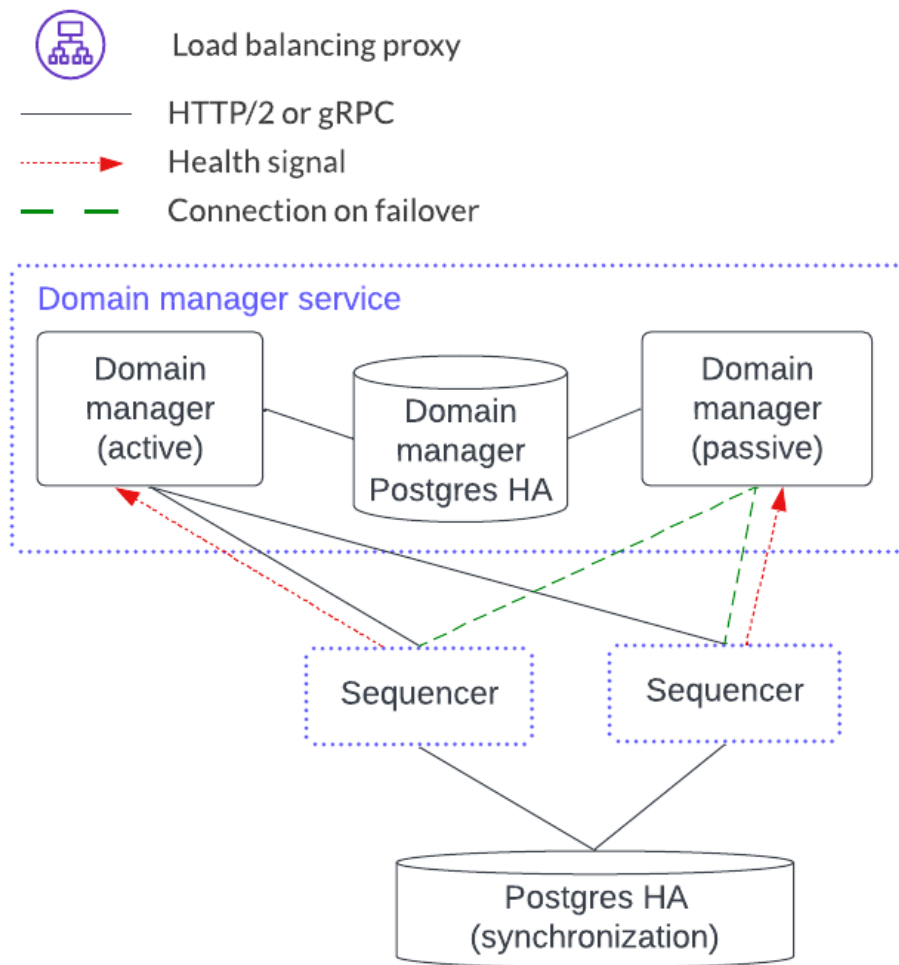

Horizontal scaling is achieved by adding another mediator service.

25.2.4.6 Synchronization Domain Manager Service

The sync domain manager service also has no client-facing ingest point. Like the mediator services, the sync domain manager is in an active-passive configuration. There is, however, only a single sync domain manager service per sync domain. This means that there is no horizontal load-balancing model for the sync domain manager. This is feasible because the sync domain manager is not in the transaction processing path and so it manages topology transactions which are orders of magnitude less frequent than the DamI transactions that the mediators manage.

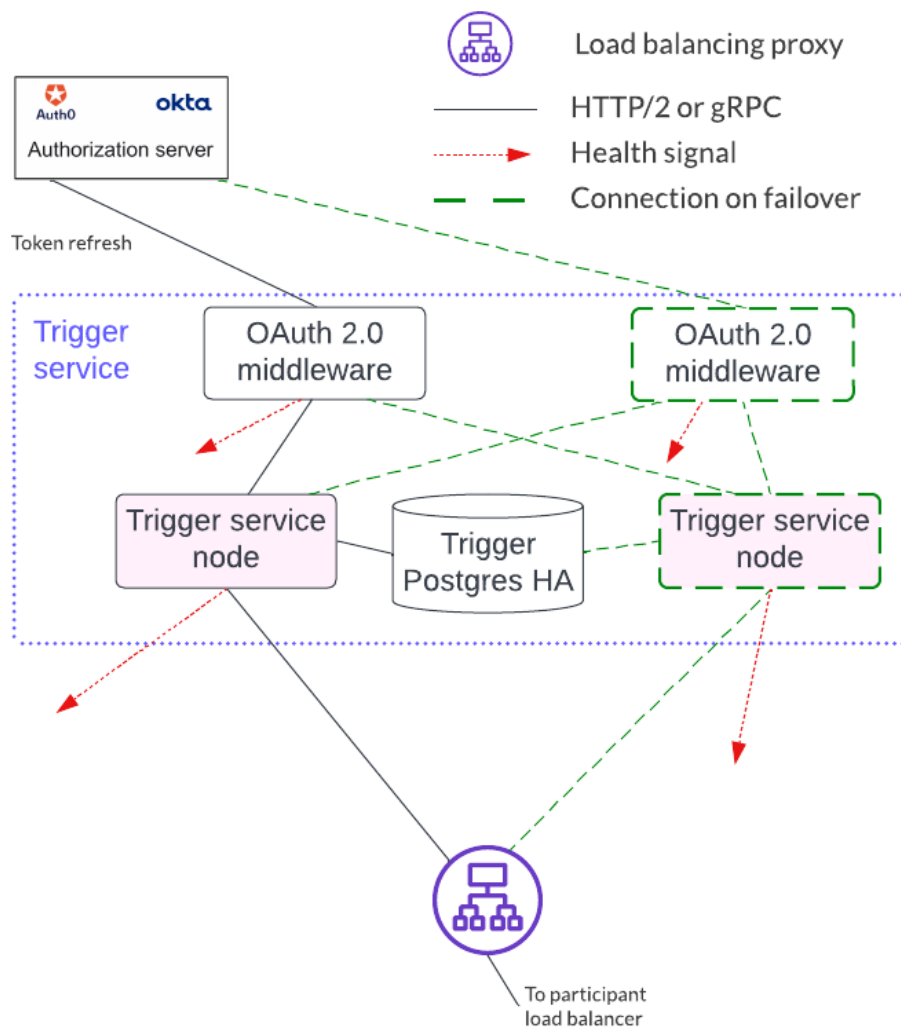

As of [v2.5.0](#), the synchronizer manager uses PostgreSQL in an HA configuration for HA support.

25.2.4.7 Trigger Service (Deprecated)

The trigger service includes the OAuth 2.0 middleware and trigger service nodes. As shown below, it does not operate in an HA configuration that supports a single failure. Instead, it requires a monitoring system to detect if the trigger service node or OAuth 2.0 middleware is unhealthy and mitigate any issues by doing one of the following:

1. Restarting the failed item.
2. Stopping the unhealthy instance and then starting another instance.

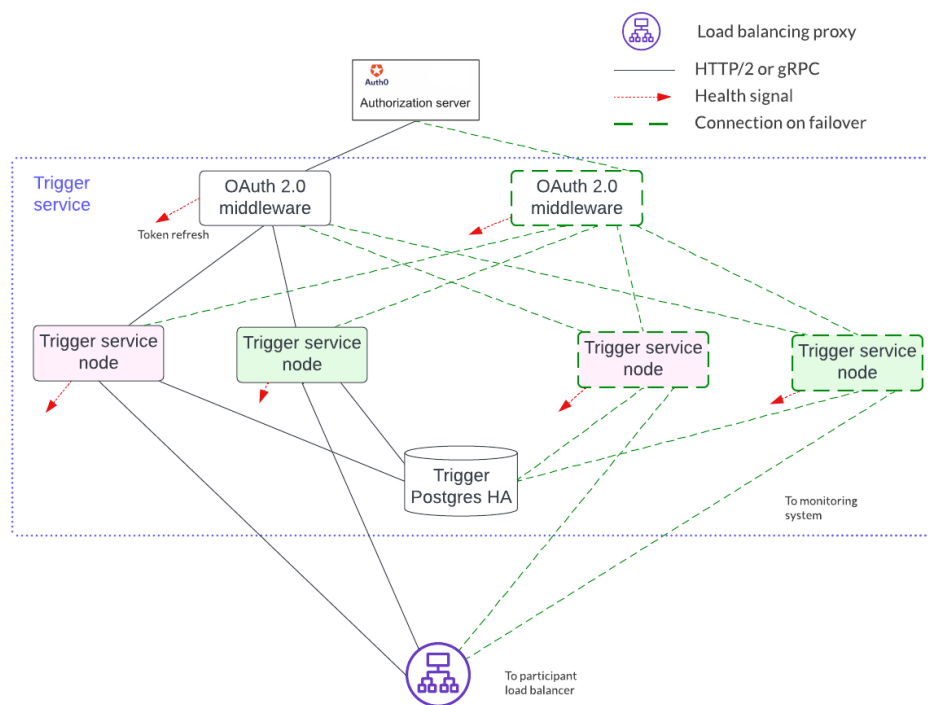

A shared PostgreSQL database is needed for the trigger service node. As shown below, the OAuth 2.0 middleware connects to an OAuth provider.

Horizontal scaling is achieved by deploying additional trigger service nodes. For example, in the figure below, there are two pairs of trigger service nodes (pink and green) which use the same OAuth 2.0 middleware node that is connected to a single OAuth provider.

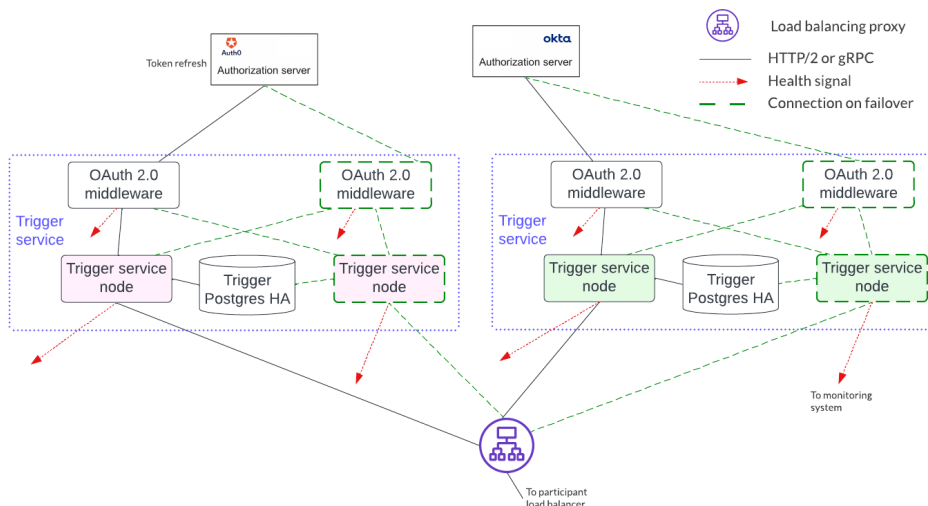

Running the same trigger rule on multiple live trigger service instances is not allowed. In this example the pink rules are running in a single live trigger service node, just like the green rules are running in a single live trigger service node.

Remember, the box with the dashed lines indicates that the node is started when the active node is identified as unhealthy.

Each trigger service node is limited to a single OAuth provider and is unable to support queries against multiple OAuth providers. For example, the pink and green trigger services in the figure above cannot query against both a Google OAuth provider and an Apple OAuth provider - each trigger service must be configured to use exactly one of these providers.

If access to more than a single OAuth provider is needed, distinct pairs of trigger service nodes and OAuth 2.0 middleware servers are configured. This is shown below. Please note running the same trigger rule on multiple live trigger service instances is not allowed in this configuration either.

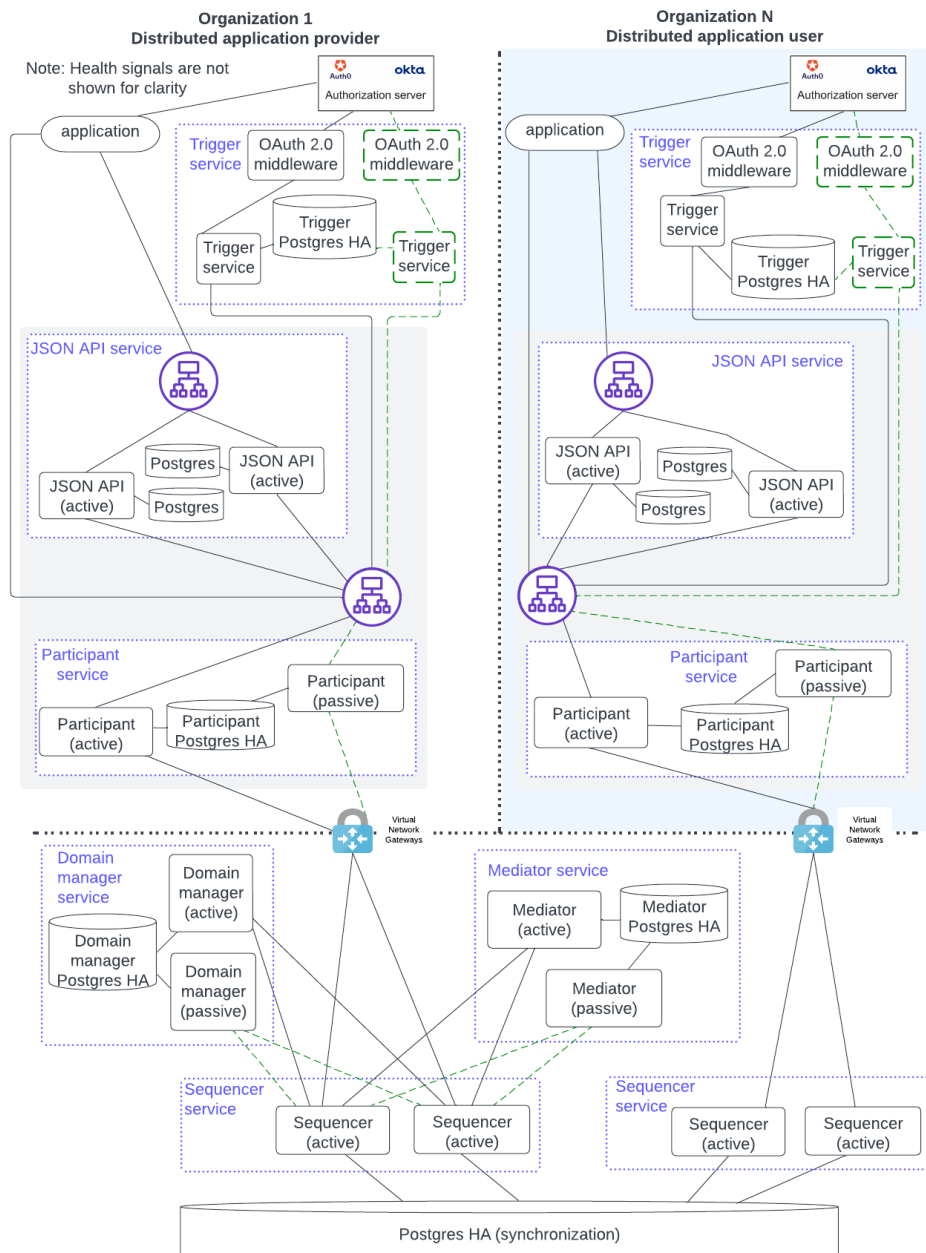

25.2.5 HA Deployment Solution for Production

The figure below assembles the components already described using the single-endpoint load balancer option. Although this setup may look complex, each service is independent and deployed separately.

The figure below uses client-side load balancing for the sync domain owner's sequencer access. Separate sequencer nodes are shown for the distributed application user's connectivity.

The diagrams maximize the independence between components by showing them as running on independent hosts. However, for actual deployment scenarios, some simplification and cost reduction is possible. For example, combining components on the same host is a decision that reduces complexity and cost but may impact availability if one component impacts another (e.g. when one component uses 100% of the CPU and starves the other components).

Distinct service instances should, in principle, run on different hosts to avoid a single point of failure at the infrastructure level. However, business goals always drive the HA requirements and how things are deployed.

25.2.6 HA in the Cloud

The HA deployment and horizontal scaling models already discussed are generic by design and focus on handling single-component failures automatically and transparently. Cloud deployment, along with orchestration tools, adds additional HA capabilities and options for more complex failure modes.

The figure below shows a minimal, high-level, AWS-based HA solution. The active nodes are green and the passive nodes are gray. Different availability zones can house different instances of the components within a service to provide location resiliency. For example, if the active participant node in US-EAST-1 fails then the passive node in US-EAST-2 becomes the active node.

Note: Network connectivity between the relevant components is not shown.

Having redundant components in different regions creates additional location resiliency. For example, in the figure above, an active participant node is deployed in the USA EAST region and a passive participant node in the USA WEST region. The redundant, passive participant may not even be running depending on how the HA solution has been architected to satisfy the business requirements, such as:

- The entire Daml solution stack may switch over to a different region all at once with a global load balancer redirecting the requests to the newly activated region. This can address the situation where a normally active region becomes unavailable.

- Single components may be started in different regions for a finer-grained HA approach. This introduces additional network latency for cross-region traffic.

- Directing a switchover from one region to another is atypical and adds complexity so this may be manually initiated, or require manual approval, to avoid flapping from one region to another when a problem is intermittent.

The sequencer backend is an HA database that can work across regions. The options are discussed below. Sequencers in an availability zone can be running since they act in an active-active mode.

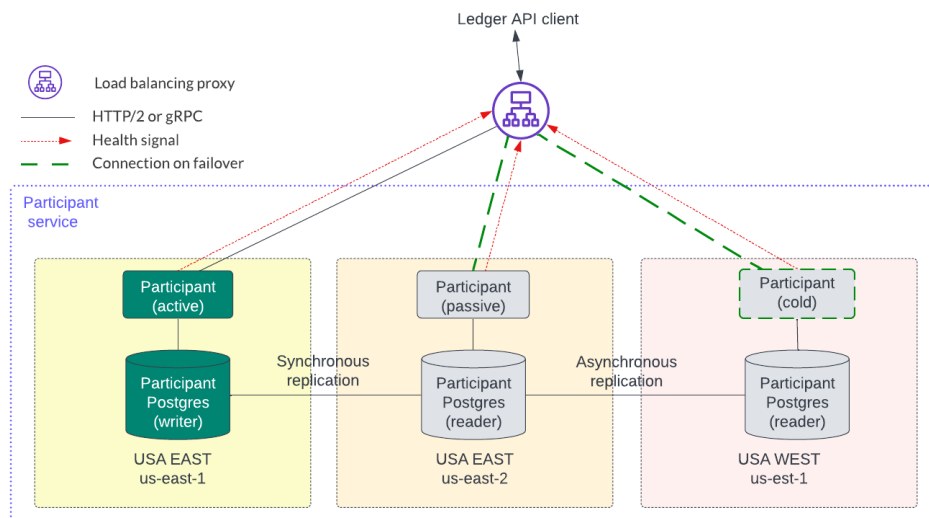

A redundant sequencer in a different region may be cold and need to be started if the PostgreSQL database it is connected to is read-only. The sequencer backend database in the example is PostgreSQL operating in a highly available manner with a single write node and read-only replicas. However, the read-only replicas and write nodes use synchronous replication to avoid data loss - the sequencer backend can look like a ledger fork to participant nodes if there is data loss.

Per AWS:

When writes involve synchronous replication across multiple Regions to meet strong consistency requirements, write latency increases by an order of magnitude. A higher write latency is not something that can typically be retrofitted into an application without significant changes.¹

Synchronous replication impacts latency and throughput so tuning and testing are needed.

Although not shown in the figure above, the databases for each service may need to be highly available and shared across availability zones and regions. To illustrate this, the participant service is expanded into three regions in the figure below. The latencies within a region are expected to be low so synchronous replication within a region provides an RPO of zero for single failures. Asynchronous replication for a participant node can be used across regions but it can incur some data loss as described in the [restore caveats documentation](#).

The initial block diagram in this section expands into the larger figure below which shows all the services acting in HA mode. The sequencer backend, participant, mediator, and sync domain manager nodes all have replicated databases ensuring no data loss.

By leveraging the elasticity of the cloud, the orchestration tool may provide possible cost reduction, at the expense of additional recovery time, by not running the passive node instances in the background. Instead, the orchestration tool starts a passive node when it detects the active node is unhealthy or has failed. In general, the node startup time is typically several seconds. However, additional time may be needed for additional data synchronization. Passive nodes can also be running

¹ <https://docs.aws.amazon.com/whitepapers/latest/aws-multi-region-fundamentals/multi-region-fundamental-2-understanding.html>

in standby mode but this incurs the cost of running those nodes.

When there is a failover in the Daml solution, some requests may not succeed. Specifically, with the Canton transaction consensus protocol either a request completes in its entirety or there are no changes. This means that, although there is no cleanup required for failed requests, the application is responsible for retrying the failed request that did not complete during a failover event. The application needs to be designed to handle this scenario (which is a common requirement for web-based applications).

See the documentation on the metrics [RTO](#) and [RPO](#) for more information.

25.2.6.1 Database Options

Each cloud vendor chooses from several PostgreSQL options. Selection is ultimately driven by business requirements, which drive the HA requirements fulfilled by selecting the appropriate PostgreSQL option. A managed database selection allows for trade-offs in availability if choosing between an Aurora DB cluster or an Aurora global database. Amazon RDS for PostgreSQL is a self-managed option which is more flexible than the managed service. Each of these options is introduced below to explore what each can provide in an HA context. Each option has a different cost profile so make sure that you are using the least costly option that matches your requirements.

Note: Multiple versions of PostgreSQL are tested for compatibility with Canton and PQS in traditional deployment configurations. PostgreSQL comes in many varieties that allow NFR trade-offs

to be made (e.g., latency Vs. read operation scaling Vs. HA Vs. cost). Not all of these variants are tested for compatibility but all are expected to work with Canton and PQS. However, sufficient application testing is required to ensure that the SLAs of the ledger API and PQS clients are met. In particular, serverless PostgreSQL has transient behaviors which require a robust application testing process to verify that application SLAs are met (e.g., transaction latency is not greatly impacted by auto-scaling).

Although the examples presented here are for AWS, other cloud vendors have similar technologies that are compatible with PostgreSQL. Please consult the relevant cloud vendors documentation.

Amazon RDS for PostgreSQL, Multi-AZ with two readable standbys²

This is a self-managed option for deploying:

highly available, durable MySQL or PostgreSQL databases in three AZs using Amazon RDS Multi-AZ with two readable standbys. Gain automatic failovers in typically under 35 seconds, up to 2x faster transaction commit latency compared to Amazon RDS Multi-AZ with one standby, additional read capacity, and a choice of AWS Graviton2 - or Intel-based instances for compute.²

Amazon Aurora database provides RPO zero at the storage level by requiring at least four of the six storage nodes to acknowledge receipt before confirming the transaction. Aurora splits the six storage nodes across Availability Zones (AZs) in an AWS Region. Amazon Relational Database Service (Amazon RDS) Multi-AZ (except SQL Server) provides close to RPO zero at the storage level independently of the database. It writes each block synchronously to two Amazon Elastic Block Storage (Amazon EBS) volumes in two different AZs.³

Amazon Aurora DB cluster⁴

This option:

consists of one or more DB instances and a cluster volume that manages the data for those DB instances. An Aurora cluster volume is a virtual database storage volume that spans multiple Availability Zones, with each Availability Zone having a copy of the DB cluster data.⁴

Additionally,

An Aurora Replica is an independent endpoint in an Aurora DB cluster, best used for scaling read operations and increasing availability. An Aurora DB cluster can include up to 15 Aurora Replicas located throughout the Availability Zones of the Aurora DB cluster's AWS Region.⁵

² <https://aws.amazon.com/rds/features/multi-az/>

³ <https://aws.amazon.com/blogs/publicsector/a-pragmatic-approach-to-rpo-zero/>

⁴ <https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/Aurora.Overview.html>

⁵ <https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/AuroraMySQLReplication.html>

Aurora global database⁶

This database:

consists of one primary AWS Region where your data is written, and up to five read-only secondary AWS Regions. You issue write operations directly to the primary DB cluster in the primary AWS Region. Aurora replicates data to the secondary AWS Regions using dedicated infrastructure, with latency typically under a second. An Aurora global database supports two different approaches to failover. ⁶

Recovery from Region-wide outages - The secondary clusters allow you to make an Aurora global database available in a new primary AWS Region more quickly (lower RTO) and with less data loss (lower RPO) than traditional replication solutions.⁶

Important: [Daml Enterprise license](#) required

25.3 High Availability Usage

This section looks at some of the components already mentioned and supplies useful Canton commands.

25.3.1 Synchronization Domain Manager

As explained in [Synchronization Domain Architecture and Integrations](#), a sync domain internally comprises a sequencer, a mediator, and a topology manager. When running a simple sync domain (configured with `canton.domains`, as shown in most of the examples), this node will be running a topology manager, a sequencer, and a mediator all internally.

It is possible to run sequencer(s) and mediator(s) as standalone nodes, as will be explained in the next topics. But to complete the sync domain setup, it is also necessary to run a sync domain manager node (configured with `canton.domain-managers`), which takes care of the bootstrapping of the distributed sync domain setup and runs the topology manager.

The sync domain bootstrapping process is explained in [Manual vs Automatic Initialization](#).

The sync domain manager can be made highly available by running an active node and an arbitrary number of replicated passive nodes on hot standby, similar to the mediator HA mechanism (see below). The only requirement is shared storage between all the sync domain manager instances, which must be either Postgres or Oracle. Nodes automatically handle their state and become active/passive whenever the active instance fails, such that from a configuration perspective this is entirely transparent.

An example configuration of a standalone HA sync domain manager node could therefore look like this:

```
canton {  
  domain-managers {  
    domainManager1 {  
      admin-api.port = 5016
```

(continues on next page)

⁶ <https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/aurora-global-database.html>

(continued from previous page)

```

    // The storage needs to be either Postgres or Oracle to support replicated
    ↪domain managers nodes
    // See the persistence section of the documentation for how to set these up
    // https://docs.daml.com/canton/usermanual/persistence.html
    storage = ${_shared.storage}
  }
}
}

```

In a replicated setup, only the active sync domain manager can be used to issue topology transactions (for instance bootstrapping a sync domain or onboarding new mediators/sequencers). To find out if a sync domain manager is active, one can run *domainManager1.health.active* in the Canton console (for a sync domain manager node named *domainManager1*). Another way to avoid this manual check is to place a load balancer in front of the sync domain managers and let it pick the active instance. See [Load Balancer Configuration](#) for more information.

Commands that indirectly use the sync domain manager (for instance connecting a participant to a sync domain) will automatically be picked up by the active sync domain manager, so this is only relevant when issuing commands directly against a specific sync domain manager.

25.3.2 HA Setup on Oracle

The HA approach that is used by the participant, mediator, and sequencer nodes requires additional permissions to be granted on Oracle to the database user.

All replicas of a node must be configured with the same DB user name. The DB user must have the following permissions granted:

```

GRANT EXECUTE ON SYS.DBMS_LOCK TO $username
GRANT SELECT ON V_$LOCK TO $username
GRANT SELECT ON V_$MYSTAT TO $username

```

In the above commands the *\$username* must be replaced with the configured DB user name. These permissions allow the DB user to request application-level locks on Oracle, as well as to query the state of locks and its own session information.

For a high-availability deployment the underlying Oracle store must be set up in a highly available manner (for example, using Oracle RAC or Veritas VCS).

Oracle high availability is supported only when the database presents to the Canton nodes as a single, logical Oracle database. There is no support for horizontal scaling through sharding or other multi-database RAC features beyond simple HA clustering.

25.3.3 Mediator

The mediator service uses a hot standby mechanism with an arbitrary number of replicas. During a mediator fail-over, all in-flight requests get purged. As a result, these requests will timeout at the participants. The applications need to retry the underlying commands.

25.3.3.1 Running a Stand-Alone Mediator Node

A sync domain may be statically configured with a single embedded mediator node or it may be configured to work with external mediators. Once the sync domain has been initialized further mediators can be added at runtime.

By default, a sync domain will run an embedded mediator node itself. This is useful in simple deployments where all sync domain functionality can be co-located on a single host. In a distributed setup where sync domain services are operated over many machines, you can instead configure a sync domain manager node and bootstrap the sync domain with mediator(s) running externally.

Mediator nodes can be defined in the same manner as Canton participants and sync domains.

```
mediators {  
  mediator1 {  
    admin-api.port = 5017  
  }  
}
```

When the sync domain starts it will automatically provide the embedded mediator information about the sync domain. External mediators have to be initialized using runtime administration in order to complete the sync domain initialization.

25.3.3.2 HA Configuration

HA mediator support is only available in the Daml Enterprise version of Canton and only PostgreSQL and Oracle-based storage are supported for HA.

Mediator node replicas are configured in the Canton configuration file as individual stand-alone mediator nodes with two required changes for each mediator node replica:

- Using the same storage configuration to ensure access to the shared database.
- Set `replication.enabled = true` for each mediator node replica.

Note: Starting from canton 2.4.0, mediator replication is enabled by default when using supported storage.

Only the active mediator node replica has to be initialized through the sync domain bootstrap commands. The passive replicas observe the initialization via the shared database.

Further replicas can be started at runtime without any additional setup. They remain passive until the current active mediator node replica fails.

25.3.4 Sequencer

The database-based sequencer can be horizontally scaled and placed behind a load balancer to provide high availability and performance improvements.

Deploy multiple sequencer nodes for the sync domain with the following configuration:

All sequencer nodes share the same database so ensure that the storage configuration for each sequencer matches.

All sequencer nodes must be configured with `high-availability.enabled = true`.

Note: Starting from Canton 2.4.0, sequencer high availability is enabled by default when using supported storage.

```
canton {
  sequencers {
    sequencer1 {
      sequencer {
        type = database
        high-availability.enabled = true
      }
    }
  }
}
```

The sync domain node only supports embedded sequencers, so a distributed setup using a sync domain manager node must then be configured to use these sequencer nodes by pointing it at these external services.

Once configured the sync domain must be bootstrapped with the new external sequencer using the [bootstrap_sync_domain](#) operational process. These sequencers share a database so just use a single instance for bootstrapping and the replicas will come online once the shared database has a sufficient state for starting.

As these nodes are likely running in separate processes you could run this command entirely externally using a remote administration configuration.

```
canton {
  remote-domains {
    da {
      # these details are provided to other nodes to use for how they should
      ↪connect to the embedded sequencer
      public-api {
        address = da-domain.local
        port = 1234
      }
      admin-api {
        address = da-domain.local
        port = 1235
      }
    }
  }

  remote-sequencers {
    sequencer1 {
      # these details are provided to other nodes to use for how they should
      ↪connect to the sequencer
      public-api {
```

(continues on next page)

(continued from previous page)

```

    address = sequencer1.local
    port = 1235
  }
  # the server used from running administration commands
  admin-api {
    address = sequencer1.local
    port = 1235
  }
}
}
}

```

There are two methods available for exposing the horizontally scaled sequencer instances to participants.

25.3.4.1 Total node count

The `sequencer.high-availability.total-node-count` parameter is used to divide up time among the database sequencers. The parameter should not be changed once a set of sequencer nodes has been deployed. Because each message sequenced must have a unique timestamp, a sequencer node will use timestamps *modulo* the `total-node-count` plus its own index to create timestamps that do not conflict with other sequencer nodes while sequencing the messages in a parallel database insertion process. Canton uses microseconds, which yields a theoretical max throughput of 1 million messages per second per sync domain. Now, this theoretical throughput is divided equally among all sequencer nodes (`total-node-count`). Therefore, if you set `total-node-count` too high, then a sequencer might not be able to operate at the maximum theoretical throughput. We recommend keeping the default value of 10, as all above explanations are only theoretical and we have not yet seen a database/hard disk that can handle the theoretical throughput. Also note that a message might contain multiple events, such that we are talking about high numbers here.

25.3.4.2 External load balancer

Using a load balancer is recommended when you have a `http2+grpc` supporting load balancer available, and can't/don't want to expose details of the backend sequencers to clients. An advanced deployment could also support elastically scaling the number of sequencers available and dynamically reconfigure the load balancer for this updated set.

An example [HAProxy](#) configuration for exposing GRPC services without TLS looks like:

```

frontend domain_frontend
  bind 1234 proto h2
  default_backend domain_backend

backend domain_backend
  option httpchk
  http-check connect
  http-check send meth GET uri /health
  balance roundrobin
  server sequencer1 sequencer1.local:1234 proto h2 check port 8080
  server sequencer2 sequencer2.local:1234 proto h2 check port 8080
  server sequencer3 sequencer3.local:1234 proto h2 check port 8080

```

Please note that for quick failover, you also need to add HTTP health checks, as otherwise, you have to wait for the TCP timeout to occur before failover happens. The public API of the sequencer exposes the standard [GRPC health endpoints](#), but these are currently not supported by HAProxy, hence you need to fall back on the HTTP/health endpoint.

25.3.4.3 Client-side load balancing

Using client-side load balancing is recommended where an external load-balancing service is unavailable (or lacks http2+grpc support), and the set of sequencers is static and can be configured at the client.

To simply specify multiple sequencers use the `domains.connect_multi` console command when registering/connecting to the sync domain:

```
myparticipant.domains.connect_multi(  
  "my_domain_alias",  
  Seq("https://sequencer1.example.com", "https://sequencer2.example.com", "https://  
↪sequencer3.example.com")  
)
```

See the [sequencer connectivity documentation](#) for more details on how to add many sequencer URLs when combined with other sync domain connection options. The sync domain connection configuration can also be changed at runtime to add or replace configured sequencer connections. Note the sync domain will have to be disconnected and reconnected at the participant for the updated configuration to be used.

25.3.5 Participant

High availability of a participant node is achieved by running multiple participant node replicas that have access to a shared database.

Participant node replicas are configured in the Canton configuration file as individual participants with two required changes for each participant node replica:

- Using the same storage configuration to ensure access to the shared database. Only PostgreSQL and Oracle-based storage is supported for HA. For Oracle it is crucial that the participant replicas use the same username to access the shared database.

- Set `replication.enabled = true` for each participant node replica.

Note: Starting from Canton 2.4.0, participant replication is enabled by default when using supported storage.

25.3.5.1 Synchronization domain connectivity during fail-over

During fail-over from one replica to another, the new active replica re-connects to all configured sync domains for which `manualConnect = false`. This means if the former active replica was manually connected to a sync domain, this sync domain connection is not automatically re-established during fail-over but must be performed manually again.

25.3.5.2 Manual trigger of a fail-over

Fail-over from the active to a passive replica is done automatically when the active replica has a failure, but one can also initiate a graceful fail-over with the following command:

```
activeParticipantReplica.replication.set_passive()
```

The command succeeds if there is at least another passive replica that takes over from the current active replica, otherwise the active replica remains active.

25.3.5.3 Load balancer configuration

Many replicated participants can be placed behind an appropriately sophisticated load balancer that will by health checks determine which participant instance is active and direct ledger and admin api requests to that instance appropriately. This makes participant replication and failover transparent from the perspective of the ledger-api application or canton console administering the logical participant, as they will simply be pointed at the load balancer.

Participants should be configured to expose an `IsActive` health status on our health HTTP server using the following monitoring configuration:

```
canton {
  monitoring {
    health {
      server {
        address = 0.0.0.0
        port = 8000
      }

      check.type = is-active
    }
  }
}
```

Once running this server will report a http 200 status code on a http/1 GET request to `/health` if the participant is currently the active replica. Otherwise, an error will be returned.

To use a load balancer it must support http/1 health checks for routing requests on a separate http/2 (GRPC) server. This is possible with [HAProxy](#) using the following example configuration:

```
global
  log stdout format raw local0

defaults
  log global
  mode http
```

(continues on next page)

(continued from previous page)

```

option httplog
# enabled so long running connections are logged immediately upon connect
option logasap

# expose the admin-api and ledger-api as separate servers
frontend admin-api
  bind :15001 proto h2
  default_backend admin-api

backend admin-api
  # enable http health checks
  option httpchk
  # required to create a separate connection to query the load balancer.
  # this is particularly important as the health HTTP server does not support h2
  # which would otherwise be the default.
  http-check connect
  # set the health check uri
  http-check send meth GET uri /health

  # list all participant backends
  server participant1 participant1.lan:15001 proto h2 check port 8080
  server participant2 participant2.lan:15001 proto h2 check port 8080
  server participant3 participant3.lan:15001 proto h2 check port 8080

# repeat a similar configuration to the above for the ledger-api
frontend ledger-api
  bind :15000 proto h2
  default_backend ledger-api

backend ledger-api
  option httpchk
  http-check connect
  http-check send meth GET uri /health

  server participant1 participant1.lan:15000 proto h2 check port 8080
  server participant2 participant2.lan:15000 proto h2 check port 8080
  server participant3 participant3.lan:15000 proto h2 check port 8080

```

Chapter 26

Disaster Recovery (DR)

Disaster recovery (DR) is the process of maintaining or reestablishing vital infrastructure and systems following a natural or human-induced disaster, such as a storm or battle. It employs policies, tools, and procedures. This section presents an overview of DR. See [Repairing Nodes](#) for the steps to recover Canton nodes in a DR situation.

Disaster recovery assumes that the primary site is not immediately recoverable and restores data and services to a secondary site.¹

DR is only briefly introduced here because it includes business-related recovery processes and mechanisms that are beyond the Daml solution. The previously introduced metrics of Recovery Point Objective (RPO) and Recovery Time Objective (RTO) are important. Recovery from disaster is typically measured using values for RTO and RPO.

In an Aurora global database used for DR, RTO can be in the order of minutes whereas RPO is typically measured in seconds. With an Aurora PostgreSQL-based global database, you can use the `rds.global_db_rpo` parameter to set and track the upper bound on RPO, but doing so might affect transaction processing on the primary cluster's writer node.

For more information, see the AWS documentation on [managing RPOs for Aurora PostgreSQL-based global databases](#).

The figure below expands on the HA AWS example by adding topology that addresses DR incidents.

¹ https://en.wikipedia.org/wiki/Disaster_recovery as retrieved 02/22/2023

DR is usually more costly to architect and deploy than an HA solution. DR is expected to occur less frequently than an HA incident so the RTO for DR is longer than HA, perhaps even allowing some data loss in a DR incident.

There are different approaches to keeping the backup databases in a DR solution as synchronized as possible to an active DB. One approach is to take frequent snapshots of the source and live database(s) and send them to the remote deployment that supports DR. The AWS documentation states the following:

You can restore a snapshot of an Aurora DB cluster or from an Amazon RDS DB instance to use as the starting point for your Aurora global database. You restore the snapshot and create a new Aurora-provisioned DB cluster at the same time. You then add another AWS Region to the restored DB cluster, thus turning it into an Aurora global database. Any Aurora DB cluster that you create using a snapshot in this way becomes the primary cluster of your Aurora global database.²

It's important to take care during and after a failover in a DR situation. AWS advises:

Make sure that application writes are sent to the correct Aurora DB cluster before, during, and after making these changes. Doing this avoids data inconsistencies among the DB clusters in the Aurora global database (split-brain issues).³

Alternatively, AWS says in Managing RPOs for Aurora PostgreSQL-based global databases:

With an Aurora PostgreSQL-based global database, you can manage the recovery point objective (RPO) for your Aurora global database by using PostgreSQL's `rds.global_db_rpo` parameter. RPO represents the maximum amount of data that can be lost in the event of an outage.

This parameter is supported by Aurora PostgreSQL. Valid values for `rds.global_db_rpo` range from 20 seconds to 2,147,483,647 seconds (68 years).⁴

Chapter 27

Persistence

Participant nodes and sync domains both require storage configurations. Both use the same configuration format and therefore support the same configuration options. There are three different configurations available:

1. `Memory` - Using simple, hash-map backed in-memory stores which are deleted whenever a node is stopped.
2. `Postgres` - To use with the open source relational database [Postgres](#).
3. `Oracle` - To use with Oracle DB (Enterprise only)

In order to set a certain storage type, we have to edit the storage section of the particular node, such as `canton.participants.myparticipant.storage.type = memory`. Memory storage does not require any other setting.

For the actual database driver, Canton does not directly define how they are configured, but leverages a third-party library ([slick](#)) for it, exposing all configuration methods therein. If you need to, please consult the [respective detailed documentation](#) to learn about all configuration options if you want to leverage any exotic option. Here, we will only describe our default, recommended and supported setup.

It is recommended to use a connection pool in production environments and [consciously choose the size of the pool](#).

Please note that Canton will create, manage and upgrade the database schema directly. You don't have to create tables yourselves.

Consult the reference `config` directory to get a set of configuration files to set your nodes up.

27.1 Postgres

Our reference driver-based definition for Postgres configuration is:

```
# Postgres persistence configuration mixin
#
# This file defines a shared configuration resources. You can mix it into your
# ↪ configuration by
# refer to the shared storage resource and add the database name.
#
# Example:
```

(continues on next page)

(continued from previous page)

```

# participant1 {
#   storage = ${_shared.storage}
#   storage.config.properties.databaseName = "participant1"
# }
#
# The user and password is not set. You want to either change this configuration
# file or pass
# the settings in via environment variables POSTGRES_USER and POSTGRES_PASSWORD.
#
_shared {
  storage {
    type = postgres
    config {
      dataSourceClass = "org.postgresql.ds.PGSimpleDataSource"
      properties = {
        serverName = "localhost"
        # the next line will override above "serverName" in case the
#environment variable POSTGRES_HOST exists
        # which makes it optional
        serverName = ${?POSTGRES_HOST}
        portNumber = "5432"
        portNumber = ${?POSTGRES_PORT}
        # user and password are required
        user = ${POSTGRES_USER}
        password = ${POSTGRES_PASSWORD}
      }
    }
    parameters {
      # If defined, will configure the number of database connections per
#node.
      # Please note that the number of connections can be fine tuned for
#participant nodes (see participant.conf)
      max-connections = ${?POSTGRES_NUM_CONNECTIONS}
      # If true, then database migrations will be applied on startup
#automatically
      # Otherwise, you will have to run the migration manually using
#participant.db.migrate()
      migrate-and-start = false
      # If true (default), then the node will fail to start if it can not
#connect to the database.
      # The setting is useful during initial deployment to get immediate
#feedback when the
      # database is not available.
      # In a production setup, you might want to set this to false to allow
#uncoordinated startups between
      # the database and the node.
      fail-fast-on-startup = true
    }
  }
}

```

You may use this configuration file with environment variables or adapt it accordingly. More detailed setup instructions and options are available in the [Slick reference guide](#). The above configurations are included in the reference config/storage folder and are sufficient to get started.

27.1.1 SSL

This snippet shows how SSL can be configured for Postgres. You can find more information about the settings in the ([postgres documentation](#)):

```
_shared {
  storage {
    type = postgres
    config {
      dataSourceClass = "org.postgresql.ds.PGSimpleDataSource"
      properties = {
        serverName = "localhost"
        serverName = ${?POSTGRES_HOST}
        portNumber = "5432"
        portNumber = ${?POSTGRES_PORT}
        user = ${POSTGRES_USER}
        password = ${POSTGRES_PASSWORD}
        # The following settings can be used to configure an SSL connection to
        ↪the Postgres DB
        ssl = true
        # Will verify that the server certificate is trusted
        sslmode= "verify-ca" # Other options and their meaning can be found
        ↪https://jdbc.postgresql.org/documentation/head/ssl-client.html

        # Optionally set with path to root certificate. Not necessary if the
        ↪server certificate can be verified using the JRE root certificates
        # sslrootcert = "path/to/root.cert"

        # For mTLS:
        # sslcert= "path/to/client-cert.pem"
        # sslkey= "path/to/client-key.pl2"
      }
    }
  }
}
```

Note that all configuration properties for the database will be propagated to the Ledger API JDBC URL.

27.1.2 Sizing and Performance

Note that your Postgres database setup requires appropriate tuning to achieve the desired performance. Canton is database-heavy. This section should give you a starting point for your tuning efforts. You may want to consult the [troubleshooting section](#) on how to analyze whether the database is a limiting factor.

This guide can give you a starting point for tuning. Ultimately, every use case is different and the exact resource requirements cannot be predicted, but have to be measured.

First, ensure that the database you are using is appropriately sized for your use case. The number of cores depends on your throughput requirements. The rule of thumb is:

- 1 db core per 1 participant core.
- 1 participant core for 30-100 ledger events per second (depends on the complexity of the commands).

The memory requirements depend on your data retention period and the size of the data you are

storing. Ideally, you monitor the database index cache hit/miss ratio. If your instance needs to keep on loading indexes from the disk, performance suffers. It might make sense to start with 128GB, run a long-running scale & performance test, and [monitor the cache hit/miss ratio](#).

Most Canton indexes are contract-id based, which means that the index lookups are randomly distributed. Solid state drives with high throughput perform much better than spinning disks for this purpose.

27.1.3 Predictability of Shared Environments

The throughput and latency of a Canton node depends on the performance of the database. Sharing hardware or software saves cost and better utilizes available resources, but it comes with some drawbacks: If the database is operated in a shared environment such as the Cloud, where other applications are using the same database or are operated on the same hardware, the performance of the Canton node varies due to contention on shared resources. This is a natural effect of shared environments and cannot be entirely avoided. It can be difficult to diagnose as a user of the shared environment due to lack of visibility into the other applications and the host system.

If you are operating in a shared environment, you should monitor the performance of the database and expect a higher variance in latency and throughput.

27.1.4 Postgres Configuration

For Postgres, [the PG Tune online tool](#) is a good starting point for finding reasonable parameters (use online transaction processing system), but you need to increase the settings of `shared_buffers`, `checkpoint_timeout` and `max_wal_size`, as explained below.

Beyond the initial configuration, note that most indexes Canton uses are hash based. Therefore, read and write access to these indexes is uniformly distributed. However, Postgres reads and writes indexes in pages of 8kb, while a simple index might only be a couple of writes. Therefore, it is very important to be able to keep the indexes in memory and only write updates to the disk from time to time; otherwise, a simple change of 32 bytes requires 8kb I/O operations.

Configuring the `shared_buffers` setting to hold 60-70% of the host memory is recommended, rather than the default suggestion of 25%, as the Postgres caching appears to be more effective than the host-based file access caching.

Also increase the following variables beyond their default: Increase the `checkpoint_timeout` so that the flushing to disk includes several writes and not just one per page, accumulated over time, together with a higher `max_wal_size` to ensure that the system does not prematurely flush before reaching the `checkpoint_timeout`. Monitor your system during load testing and tune the parameters accordingly to your use case. The downside of changing the checkpointing parameters is that crash recovery takes longer.

27.2 Oracle

Important: [Daml Enterprise license](#) required

An Oracle database can be used as the local persistence for the Canton nodes. The enterprise version of Canton comes with default configuration mixins using Oracle as a database backend.

Persistence using Oracle has the following dependencies:

- Oracle Database 19c - requires version 19.11 or later
- Oracle Text 19c - a plugin schema to oracle database
- Intel x86-64 architecture

27.2.1 Installation and Setup of Oracle

Assuming that Oracle has already been installed, the following configuration aspects and setup steps are required.

27.2.1.1 Default Character Set and Collations

The database must use the recommended Oracle defaults for character sets and collations:

```
AL32UTF8 encoding for NLS_CHARACTERSET
AL32UTF8 or AL16UTF16 for NLS_NCHAR_CHARACTERSET
BINARY for NLS_SORT and NLS_COMP
```

Otherwise, Canton will refuse to connect to the database and log an error message of the form

```
DatabaseConfigError(Oracle NLS database parameter ... is ..., but should be ...)
```

In addition to keeping the default database character set and collations configurations, the Java user language must be set to `en` and the user country to `US` (the default on most systems). This can be forced by setting the `JAVA_OPTS` options via the command line additions `-Duser.language=en` `-Duser.country=US` (see [JVM Arguments](#)). Otherwise the node at startup may complain about session `NLS_SORT` or `NLS_COMP` being different from `BINARY` by logging these strings:

```
DatabaseConfigError(Oracle NLS session parameter NLS_SORT is ..., but
should be BINARY)
DatabaseConfigError(Oracle NLS session parameter NLS_COMP is ..., but
should be BINARY)
```

27.2.1.2 Database Replication

To allow for recovery from data loss due to catastrophic events at data centers, database replication should be enabled. The technical details of setting up replication are out of scope of this manual. Canton on Oracle assumes that a database transaction is reported as committed only after it has been persisted to all database replicas. Please make sure this is the case to prevent data corruption / data loss in case of a data center failover.

27.2.1.3 Setup Oracle Schemas

For a simple Oracle-based Canton deployment with one sync domain and one participant the following Oracle schemas (i.e., users) are required:

Component	Schema name	Description	Authentication
Oracle sync domain	DD4ODRUN	Runtime user	Password configured per 2.2.7 Site administrator may change at will (i.e., default password is never hardcoded or assumed)
Participant	DD4OPRUN	Runtime user for Participant Canton component	
	DD4OPLEDG	Runtime user for Participant API ledger component	

The DD4ODRUN, DD4OPRUN, and DD4OPLEDG users all need the following schema privileges:

- Quota Unlimited
- Create table
- Create type
- Create session
- Create view
- Create procedure
- Create sequence

Run the following commands as the system user (e.g., for the runtime user (DD4OPRUN) provisioning using Oracle SQL*Plus from the command line):

```
SQL> CREATE USER DD4OPRUN IDENTIFIED BY securepass;
SQL> ALTER USER DD4OPRUN QUOTA UNLIMITED ON USERS;
SQL> GRANT CREATE TABLE, CREATE TYPE, CREATE SESSION, CREATE VIEW, CREATE
PROCEDURE, CREATE SEQUENCE, CREATE TRIGGER TO DD4OPRUN;
SQL> GRANT EXECUTE ON SYS.DBMS_LOCK TO DD4OPRUN;
SQL> GRANT SELECT ON V_$MYSTAT TO DD4OPRUN;
SQL> GRANT SELECT ON V_$LOCK TO DD4OPRUN;
SQL> GRANT SELECT ON V_$PARAMETER TO DD4OPRUN;
```

For additional sync domains or participant nodes create the corresponding schemas with one schema per node.

If you are getting an error message like:

```
ORA-65096: invalid common user or role name
```

you are most likely logged into the CDB instead of the PDB. Find the right PDB and change the session:

```
SQL> show pdbs
SQL> alter session SET container = ORCLPDB1;
```

You can then test whether creating the user worked using `sqlplus`:

```
sqlplus -L DD4OPRUN/securepass@ORCLPDB1
```

27.2.2 Configuring Canton Nodes for Oracle

The following is an example configuration for an Oracle-backed sync domain for the persistence of its sequencer, mediator, and topology manager nodes. The placeholders `<ORACLE_HOST>`, `<ORACLE_PORT>`, and `<ORACLE_DB>` will need to be replaced with the correct settings to match the environment and `<ORACLE_USER>` with a unique user for each node:

```
_shared {
  // Please note that this configuration only applies for domain nodes. Use
  ↪oracle-participant.conf to run a participant node with Oracle storage
  storage {
    type = oracle
    config {
      driver = "oracle.jdbc.OracleDriver"
      url = "jdbc:oracle:thin:@${ORACLE_HOST}:${ORACLE_PORT}/${ORACLE_DB}"
      password = ${ORACLE_PASSWORD}
      user = ${ORACLE_USER}
    }
  }
}
```

The environment variable for `ORACLE_PASSWORD` needs to be set and exported so that it is accessible for substitution in the configuration files.

The persistence configuration for the Participant is an extended version-based on the previous configuration for participant nodes with the addition of the Ledger API JDBC URL string:

```
include required("oracle.conf")
// note: the ledger api server (part of a canton system) requires a separate
↪schema (user) in oracle
// because of that, you need to set up a second user. here, we assume the second
↪user is set up on the same oracle db
// host using the same password as the participant schema
_shared.storage.parameters.ledger-api-jdbc-url = "jdbc:oracle:thin:${ORACLE_USER_
↪LAPI}/${ORACLE_PASSWORD}@${ORACLE_HOST}:${ORACLE_PORT}/${ORACLE_DB}"
```

27.2.3 Performance Tuning

The following configuration changes serve as an example to tune the performance of Oracle. **NOTE:** The configuration changes need to be reviewed and adapted to the specific application and environment.

27.2.3.1 Operating System Modifications

Runtime Kernel Parameters

The recommended Linux kernel is version 5.10 or later. For RHEL systems, a mainline kernel can be installed from ELRepo, as follows:

```
$ sudo dnf -y install https://www.elrepo.org/elrepo-release-8.el8.elrepo.noarch.  
↪rpm  
$ sudo rpm --import https://www.elrepo.org/RPM-GPG-KEY-elrepo.org  
$ sudo dnf makecache  
$ sudo dnf --disablerepo="*" --enablerepo="elrepo-kernel" install -y kernel-ml.  
↪x86_64
```

By default, the Linux kernel default settings are optimized for general-purpose applications, and as such these settings can be unsuitable or even detrimental to the performance and stability of I/O-heavy applications, like databases.

Make the following additions to `/etc/sysctl.conf`

```
vm.swappiness = 5  
vm.dirty_background_ratio = 5  
vm.dirty_background_bytes = 25  
vm.nr_hugepages = 200  
fs.file-max = 6815744  
kernel.sem = 250 32000 100 128  
kernel.shmni = 4096  
kernel.shmall = 1073741824  
kernel.shmmax = 4398046511104  
kernel.panic_on_oops = 1  
net.core.rmem_default = 262144  
net.core.rmem_max = 4194304  
net.core.wmem_default = 262144  
net.core.wmem_max = 1048576  
net.ipv4.conf.all.rp_filter = 2  
net.ipv4.conf.default.rp_filter = 2  
fs.aio-max-nr = 1048576  
net.ipv4.ip_local_port_range = 9000 65500
```

Either reboot the database server host or apply the changes to a running server by running the following command from the terminal: `sudo sysctl -p`. Upon successfully applying the new settings, `sysctl` will output the newly applied values to the console.

Shared Memory (SHM) Segments

Oracle database works best when it can keep as much working data in memory as possible, shared amongst the different subsystems, running in their own distinct OS-level processes. This memory space is used by the database System Global Area (SGA) for allocating the buffer cache pools, shared and large pools, Java process pools and stream pools, among other functions. To allocate 80% of

total system memory (RAM) to the database instance, you need to allocate fractionally more system memory to the shared memory area on the OS level.

Run this command to calculate the allocation size of the SHM:

```
$ printf "%.0f\n" `echo "(\`grep MemTotal /proc/meminfo | awk '{print $2}'\`/  
↪1024)*.82" | bc -s`  
105712
```

Next, update `/etc/fstab` to ensure the allocation:

```
$ grep shm /etc/fstab  
tmpfs          /dev/shm       tmpfs          rw,nosuid,nodev,size=105712m    0      0
```

Again, either reboot the database server host, or apply the changes to a running server by remounting the SHM tmpfs filesystem:

```
$ sudo mount -o remount /dev/shm  
Verify the new settings:  
$ df -h -BM -P /dev/shm  
Filesystem      1048576-blocks    Used Available Capacity Mounted on  
tmpfs           105712M 38912M      66800M      37% /dev/shm
```

27.2.3.2 System Container Configuration (CDB)

The System Container stores the system settings and metadata required to manage all user databases. Now modify some of the default performance settings, in multiple stages.

After each stage restart the service from within the `sqlplus` client, as follows:

```
SQL> SHUTDOWN;  
SQL> STARTUP;  
SQL> ALTER PLUGGABLE DATABASE ALL OPEN;  
SQL> ALTER SYSTEM REGISTER;
```

Stage 1: Increase Database Memory Allocation

Allocate 80% of total available system memory to the database instance. First, calculate the value on the command line, as follows:

```
$ printf "%.0f\n" `echo "(\`grep MemTotal /proc/meminfo | awk '{print $2}'\`/  
↪1024)*.8" | bc -s`  
103134
```

From the database client connected to the CDB, set the memory cap, and restart the database:

```
SQL> ALTER SYSTEM SET MEMORY_TARGET = 103134M SCOPE = SPFILE;
```

Stage 2: Set Runtime Values

Also allocate 40% of total available system memory to the database's Program Global Area (PGA). The PGA is a non-shared memory region that is allocated to the CDB when the server starts. The PGA regions are also allocated per-process in the user database, and you will allocate a total amount to be used by all processes.

Again calculate the value on the command line, as follows:

```
$ printf "%.0f\n" `echo "(\`grep MemTotal /proc/meminfo | awk '{print $2}'\`/
↳1024)*.4" | bc -s`
51462
```

From the database client connected to the CDB, set the following and restart the database:

```
SQL> ALTER SYSTEM SET PGA_AGGREGATE_TARGET = 51462M SCOPE = BOTH;
SQL> ALTER SYSTEM SET RESOURCE_LIMIT = FALSE SCOPE = BOTH;
SQL> ALTER SYSTEM SET OPEN_CURSORS = 16000 SCOPE = SPFILE;
SQL> ALTER SYSTEM SET JOB_QUEUE_PROCESSES = 2000 SCOPE = BOTH;
SQL> ALTER SYSTEM SET USE_LARGE_PAGES = TRUE SCOPE = SPFILE;
SQL> ALTER SYSTEM SET SESSION_MAX_OPEN_FILES = 50 SCOPE = SPFILE;
SQL> ALTER SYSTEM SET PARALLEL_DEGREE_POLICY = AUTO SCOPE = BOTH;
SQL> ALTER SYSTEM SET DB_BIG_TABLE_CACHE_PERCENT_TARGET = 20 SCOPE = SPFILE;
SQL> ALTER SYSTEM SET DB_CACHE_SIZE = 8G SCOPE = SPFILE;
SQL> ALTER SYSTEM SET JAVA_POOL_SIZE = 8G SCOPE = SPFILE;
SQL> ALTER SYSTEM SET OPTIMIZER_ADAPTIVE_REPORTING_ONLY = TRUE SCOPE = BOTH;
SQL> ALTER SYSTEM SET OPTIMIZER_ADAPTIVE_STATISTICS = TRUE SCOPE = BOTH;
SQL> ALTER SYSTEM SET OPTIMIZER_SESSION_TYPE = ADHOC SCOPE = SPFILE;
SQL> ALTER SYSTEM SET OPTIMIZER_USE_PENDING_STATISTICS = TRUE SCOPE = BOTH;
SQL> ALTER SYSTEM SET FILESYSTEMIO_OPTIONS = SETALL SCOPE = SPFILE;
SQL> ALTER SYSTEM SET DISK_ASYNC_IO = TRUE SCOPE = SPFILE;
SQL> ALTER SYSTEM SET PARALLEL_THREADS_PER_CPU = 8 SCOPE = BOTH;
SQL> ALTER SYSTEM SET PARALLEL_DEGREE_LIMIT = IO SCOPE = BOTH;

-- NOTE: The following setting is recommended, but optional; some users have
↳reported high memory usage when enabled.
SQL> ALTER SYSTEM SET OPTIMIZER_CAPTURE_SQL_PLAN_BASELINES = TRUE SCOPE = BOTH;
```

NOTE: Please avoid setting explicit process and session limits. Oracle will derive intelligent limits for you. If you still need to set explicit limits on your database, please ensure that the limits are sufficiently high for the nodes that you intend to run. We recommend configuring at least **6 times more connections per node** than actively used to give sufficient buffer for [delayed connection clean-up by Oracle](#). The max connection settings can be configured as explained in [Max Connection Settings](#).

If your database resource limits are lower than the database connections created by the nodes, the nodes will fail to properly start or operate. If you set the number of connections too low, the system will not perform at peak throughput.

Stage 3: Configure Pluggable Database (PDB) Runtime Values

A Pluggable Database (PDB) is a user-created set of schemas, objects, and related structures that appears logically to a client application as a separate database. Do some initial configuration of the PDB to ensure it can meet the performance requirements of the your application, after which you will create new user schemas in the PDB.

If your application requires significantly larger tablespace, Oracle will resize tablespaces on-the-fly, meaning persistence grows gradually over time to fit the size requirements of the application; however, this comes at the expense of performance, as the database regularly performs blocking I/O operations to resize tablespaces, resulting in a volatile system load profile and overall reduced transaction throughput.

Overcome this limitation by pre-allocating new TEMP, USERS and UNDO tablespaces:

```
SQL> CREATE BIGFILE TEMPORARY TABLESPACE temp_bigfile TEMPFILE '/opt/oracle/
↳oradata/ORCLCDB/ORCLPDB1/temp_bigfile_01.dbf' SIZE 1T AUTOEXTEND ON MAXSIZE
↳UNLIMITED;
```

(continues on next page)

(continued from previous page)

```
SQL> CREATE BIGFILE UNDO TABLESPACE undo_bigfile DATAFILE '/opt/oracle/oradata/
↳ORCLCDB/ORCLPDB1/undo_bigfile_01.dbf' SIZE 1T AUTOEXTEND ON MAXSIZE UNLIMITED
↳RETENTION GUARANTEE;
SQL> CREATE BIGFILE TABLESPACE users_bigfile DATAFILE '/opt/oracle/oradata/
↳ORCLCDB/ORCLPDB1/users_bigfile_01.dbf' SIZE 6T AUTOEXTEND ON MAXSIZE UNLIMITED;
```

And then reconfigure the PDB to use the new tablespaces by default:

```
SQL> ALTER DATABASE SET DEFAULT BIGFILE TABLESPACE;
SQL> ALTER DATABASE DEFAULT TEMPORARY TABLESPACE TEMP_BIGFILE;
SQL> ALTER DATABASE DEFAULT TABLESPACE USERS_BIGFILE;
SQL> ALTER SYSTEM SET UNDO_TABLESPACE = UNDO_BIGFILE SCOPE = BOTH;
```

Change the default retention to 30 minutes, giving better transaction rollback performance, after which you will restart the database:

```
SQL> ALTER SYSTEM SET UNDO_RETENTION = 1800 SCOPE = BOTH;
```

27.3 General Settings

27.3.1 Max Connection Settings

The storage configuration can further be tuned using the following additional setting:

```
canton.participants.<service-name>.storage.parameters.max-connections = X
```

This allows you to set the maximum number of DB connections used by a Canton node. If the value is None or non-positive, the value will be the number of processors. The setting has no effect if the number of connections is already set via slick options (i.e. `storage.config.numThreads`).

If you are unsure how to size your connection pools, [this article](#) may be a good starting point.

Generally, the number of connections should be up to two times the number of CPUs on the database machine.

The number of parallel indexer connections can be configured via

```
canton.participants.<participant-name>.parameters.ledger-api-server-parameters.
↳indexer.ingestion-parallelism = Y
```

The number Z of the connections used by the exclusive sequencer writer component is the final parameter that can be controlled.

```
canton.sequencers.<sequencer-name>.sequencer.high-availability.exclusive-storage.
↳max-connections = Z
```

A Canton participant node will establish up to $X + Y + 2$ permanent connections with the database, whereas a sync domain will use up to X permanent connections, except for a sequencer with HA setup that will allocate up to $2X$ connections. During startup, the node will use an additional set of at most X temporary connections during database initialisation.

The number X represents an upper bound of permanent connections and is divided internally for different purposes, depending on the implementation. Consequently, the actual size of the write

connection pool, for example, could be smaller. Some of the allotted connections will be taken by the *read* pool, some will be taken by the *write* pool, and a single additional connection will be reserved to a dedicated *main* connection responsible for managing the locking mechanism.

The following table summarizes the detailed split of the connection pools in different Canton nodes. *R* signifies a *read* pool, *W* a *write* pool, *A* a *ledger api* pool, *I* an *indexer* pool, *RW* a combined *read/write* pool, and *M* the *main* pool.

Node Type	Enterprise Edition with Replication	Enterprise Edition	Community Edition
Participant	$A = X / 2$ $R = X / 4$ $W = X / 4 - 1$ $M = 1$ $I = Y$	$A = X / 2$ $R = X / 4$ $W = X / 4 - 1$ $M = 1$ $I = Y$	$A = X / 2$ $RW = X / 2$ $I = Y$
Mediator	$R = X / 2$ $W = X / 2 - 1$ $M = 1$	N/A	N/A
Sequencer	$RW = X$	N/A	N/A
Sequencer writer	$R = X / 2$ $W = X / 2 - 1$ $M = 1$	N/A	N/A
Sequencer exclusive writer	$R = Z / 2$ $W = Z / 2$	N/A	N/A
Sync domain manager	$R = X / 2$ $W = X / 2 - 1$ $M = 1$	N/A	N/A
Sync domain	N/A	$RW = X$	$RW = X$

The results of the divisions are always rounded down unless they yield a zero. In that case, a minimal pool size of 1 is ascertained.

The values obtained from that formula can be overridden using explicit configuration settings for the *ledger API A*, the *read R*, the *write W* pools.

```
canton.participants.<participant-name>.storage.parameters.connection-allocation.  
↪ num-reads = R-overwrite
```

(continues on next page)

(continued from previous page)

```
canton.participants.<participant-name>.storage.parameters.connection-allocation.  
↳num-writes = W-overwrite  
canton.participants.<participant-name>.storage.parameters.connection-allocation.  
↳num-ledger-api = A-overwrite
```

Similar parameters exist also for other Canton node types:

```
canton.sequencers.sequencer.storage.parameters.connection-allocation...  
canton.mediators.mediator.storage.parameters.connection-allocation...  
canton.domain-managers.domain_manager.storage.parameters.connection-allocation...
```

Where a node operates a combined *read/write* connection pool, the numbers for *R* and *W* overwrites are added together to determine the overall pool size.

The effective connection pool sizes are reported by the Canton nodes at startup.

```
INFO c.d.c.r.DbStorageMulti$:participant=participant_b - Creating storage, num-  
↳reads: 5, num-writes: 4
```

27.3.2 Queue Size

Canton may schedule more database queries than the database can handle. As a result, these queries will be placed into the database queue. By default, the database queue has a size of 1000 queries. Reaching the queueing limit will lead to a `DB_STORAGE_DEGRADATION` warning. The impact of this warning is that the queuing will overflow into the asynchronous execution context and slowly degrade the processing, which will result in fewer database queries being created. However, for high-performance setups, such spikes might occur more regularly. Therefore, to avoid the degradation warning appearing too frequently, the queue size can be configured using:

```
canton.participants.participant1.storage.config.queueSize = 10000
```

27.4 Backup and Restore

It is recommended that your database is frequently backed up so that the data can be restored in case of a disaster.

In the case of a restore, a participant can replay missing data from the sync domain as long as the sync domain's backup is more recent than that of the participant's.

27.4.1 Order of Backups

It is important that the participant's backup is not more recent than that of the domain's, as that would constitute a ledger fork. Therefore, if you back up both participant and domain databases sequentially, the following constraints apply:

- If you run a composite domain node, always back up the participant database before the domain.

- If you run different nodes of the domain separately (sequencer, mediators, domain topology manager):

- Back up the mediators, the domain manager, and participants before the sequencer; otherwise, they may not be able to reconnect to the sequencer (`ForkHappened`). The relative order of mediators, domain topology manager, and participants does not matter.
- On a [permissioned domain](#), make sure no participant is registered with the domain topology manager between the backup of the domain topology manager and the backup of the sequencer. Otherwise, the participant may not work correctly after the recovery.

If you perform a complete system backup in a single step (for example, using a cloud RDS), make sure no component writes to the database while the backup is in progress.

If you are using a domain integration such as Fabric or Besu, back up the sequencer node before backing up the underlying domain storage (e.g. Besu files).

In case of a sync domain restore from a backup, if a participant is ahead of the sync domain the participant will refuse to connect to the sync domain (`ForkHappened`) and you must either:

- restore the participant's state to a backup before the disaster of the sync domain, or
- roll out a new sync domain as a repair strategy in order to [recover from a lost sync domain](#)

The state of applications that interact with a participant's ledger API must be backed up before the participant, otherwise the application state has to be reset.

27.4.2 Restore Caveats

When restoring Canton nodes from a backup, the following caveats apply due to the loss of data between the point of backup and latest state of the nodes.

27.4.2.1 Incomplete Command Deduplication State

After the restore, the participant's in-flight submission tracking will be out of sync with what the participant has sent to the sequencer after the backup was taken. If an application resubmits a duplicate command it may get accepted even though it should have been deduplicated by the participant.

This tracking will be in sync again when:

- the participant has processed all events from the sequencer, and
- no queue on the sequencer includes any submission request of a transfer/transaction request from before the restore that could be sequenced again

Such submission requests have a max sequencing time of the ledger time plus the ledger-time-record-time-tolerance of the sync domain. It should be enough to observe a timestamp from the sync domain that is after the time when the participant was stopped before the restore by more than the tolerance. Once such a timestamp is observed, the in-flight submission tracking is in sync again and applications can resume submitting commands with full command deduplication guarantees.

27.4.2.2 Application State Reset

If the application's state is newer than the participant's state, either because the application was backed up after the participant or because the application is run by a different organization and wasn't restored from a backup, then the application state has to be reset. Otherwise the application has already requested and processed transactions that were lost by the participant due to the gap between when the backup was taken and when the node disaster happened.

This includes all applications that are ledger API clients of the participant, including the JSON API server.

27.4.2.3 Private Keys

Assume a scenario in which a node needs to rotate its cryptographic private key, which is currently stored in the database of the node. If the key rotation has been announced in the system before a backup has been performed, the new key will not be available on a restore, but all other nodes in the system expect the new key to be used.

To avoid this situation, perform the key rotation steps in this order:

1. Generate the new private key and store it in the database
2. Back up the database
3. Once the backup is complete, revoke the previous key

27.4.3 Postgres Example

If you are using Postgres to persist the participant node or sync domain data, you can create backups to a file and restore it using Postgres's utility commands `pg_dump` and `pg_restore` as shown below:

Backing up Postgres database to a file:

```
pg_dump -U <user> -h <host> -p <port> -w -F tar -f <fileName> <dbName>
```

Restoring Postgres database data from a file:

```
pg_restore -U <user> -h <host> -p <port> -w -d <dbName> <fileName>
```

Although the approach shown above works for small deployments, it is not recommended for larger deployments. For that, we suggest looking into incremental backups and refer to the resources below:

[PostgreSQL Documentation: Backup and Restore](#)
[How incremental backups work in PostgreSQL](#)

27.5 Database Replication for Disaster Recovery

27.5.1 Synchronous Replication

We recommend that in production at least the sync domain should be run with offsite synchronous replication to ensure that the state of the sync domain is always newer than the state of the participants. However to avoid similar [caveats as with backup restore](#) the participants should either use synchronous replication too or as part of the manual disaster recovery failure procedure the caveats have to be addressed.

A database backup allows you to recover the ledger up to the point when the last backup was created. However, any command accepted after creation of the backup may be lost in case of a disaster. Therefore, restoring a backup will likely result in data loss.

If such data loss is unacceptable, you need to run Canton against a replicated database, which replicates its state to another site. If the original site is down due to a disaster, Canton can be started in the other site based on the replicated state in the database. It is crucial that there are no writers left in the original site to the database, because the database mechanism used in Canton to avoid multiple writers and thus avoid data corruption does not work across sites.

For detailed instructions on how to setup a replicated database and how to perform failovers, we refer to the database system documentation, e.g. [the high availability documentation](#) of PostgreSQL.

It is strongly recommended to configure replication as synchronous. That means, the database should report a database transaction as successfully committed only after it has been persisted to all database replicas. In PostgreSQL, this corresponds to the setting `synchronous_commit = on`. If you do not follow this recommendation, you may observe data loss and/or a corrupt state after a database failover. Enabling synchronous replication may impact the performance of Canton depending on the network latency between the primary and offsite database.

For PostgreSQL, Canton strives to validate the database replication configuration and fail with an error, if a misconfiguration is detected. However, this validation is of a best-effort nature; so it may fail to detect an incorrect replication configuration. For Oracle, no attempt is made to validate the database configuration. Overall, you should not rely on Canton detecting mistakes in the database configuration.

Chapter 28

Canton Administration Quickstart

28.1 Use the Canton Command Line

Canton supports a variety of command line arguments. Please run `bin/canton --help` to see all of them. Here, we explain the most relevant ones.

28.1.1 Selecting a Configuration

Canton requires a configuration file to run. There is no default topology configuration built in and therefore, the user needs to at least define what kind of node (sync domain or participant) and how many they want to run in the given process. Sample configuration files can be found in our release package, under the `examples` directory.

When starting Canton, configuration files can be provided using

```
bin/canton --config conf_filename -c conf_filename2
```

which will start Canton by merging the content of `conf_filename2` into `conf_filename`. Both options `-c` and `--config` are equivalent. If several configuration files assign values to the same key, the *last* value is taken. The section on [static configuration](#) explains how to write a configuration file.

You can also specify config parameters on the command line, alone or along with configuration files, to specify missing parameters or to overwrite others. This can be useful for providing simple short config info. Config parameters can be provided using `-C`:

```
bin/canton --config conf_filename -C canton.participants.participant1.storage.  
↪type=memory
```

28.1.2 Run Modes

Canton can run in three different modes, depending on the desired environment and task.

28.1.2.1 Interactive Console

The default method to run Canton is in the interactive mode. The process will start [a command line interface](#) (REPL) which allows to conveniently operate, modify and inspect the Canton application.

In this mode, all errors will be reported as `CommandExecutionException` to the console, but Canton will remain running.

The interactive console can be started together with a script, using the `--bootstrap-script=...` option. The script uses the same syntax as the console.

The interactive mode is useful for development, education and expert use.

28.1.2.2 Daemon

If the console is undesired such as in server operation, Canton can be started in daemon mode

```
bin/canton daemon --config ...
```

All configured entities will be automatically started and will resume operation.

A failure to connect to the database storage will lead the process to exit with a non-zero exit code. This can be turned off using:

```
canton.participants.participant1.storage.parameters.fail-fast-on-startup = "no"
```

Any failures encountered while running the bootstrap script will immediately shutdown the Canton process with a non-zero exit code.

Nodes started in daemon mode can be administrated by setting up a [remote console](#) that provides the interactive user experience, while the nodes run in a separate process.

28.1.2.3 Headless Script Mode

For testing and scripting purposes, Canton can also start in headless script mode:

```
bin/canton run <script-path> --config ...
```

In this case, commands are specified in a script rather than executed interactively. Any errors with the script or during command execution should cause the Canton process to exit with a non-zero exit code.

28.1.2.4 Interactive Server Process using Screen

In some situations, we find it convenient to run even a server process interactively. For server use on Linux / OSX, this can be accomplished by using the [screen](#) command:

```
screen -S canton -d -m ./bin/canton -c ...
```

will start the Canton process in a screen session named `canton` which does not terminate on user-logout and therefore allows to inspect the Canton process whenever necessary.

A previously started process can be joined using

```
screen -r canton
```

and an active screen session can be detached using CTRL-A + D (in sequence). Be careful and avoid typing CTRL-D, as it will terminate the session. The screen session will continue to run even if you log out of the machine.

28.1.3 Java Virtual Machine Arguments

The `bin/canton` application is a convenient wrapper to start a Java virtual machine running the Canton process. The wrapper supports providing additional JVM options using the `JAVA_OPTS` environment variable or using the `-D` command line option.

For example, you can configure the heap size as follows:

```
JAVA_OPTS="-Xmx2G" ./bin/canton --config ...
```

There are several log related options that can be specified. Refer to [Logging](#) for more details.

28.2 Canton Console

Canton offers a console (REPL) where entities can be dynamically started and stopped, and a variety of administrative or debugging commands can be run.

All console commands must be valid Scala (the console is built on [Ammonite](#) - a Scala-based scripting and [REPL](#) framework). Note that we also define [a set of implicit type conversions](#) to improve the console usability: notably, whenever a console command requires a [DomainAlias](#), [Fingerprint](#) or [Identifier](#), you can instead also call it with a `String` which will be automatically converted to the correct type (i.e., you can, e.g., write `participant1.domains.get_agreement("domain1")` instead of `participant1.domains.get_agreement(DomainAlias.tryCreate("domain1"))`).

The `examples/` sub-directories contain some sample scripts, with the extension `.canton`.

- [Node References](#)
- [Help](#)
- [Lifecycle Operations](#)

[Timeouts](#)[Code-Generation in Console](#)[Canton Administration APIs](#)

Commands are organized by thematic groups. Some commands also need to be explicitly turned on via configuration directives to be accessible.

Some operations are available on both types of nodes, whereas some operations are specific to either participant nodes or sync domains. For consistency, we organize the manual by node type, which means that some commands will appear twice. However, the detailed explanations are only given within the participant documentation.

28.2.1 Remote Administration

The Canton console works with both local in-process nodes and remote nodes. Once you've configured the network address, port, and authentication information, you can use a single Canton console to administer all the nodes in your system.

As an example, you might have previously started a Canton instance in daemon mode using something like the following:

```
./bin/canton daemon -c <some config>
```

You can then execute commands against this up-and-running participant using a `remote-participant` configuration such as:

```
// Example remote participant configuration

// Include TLS configuration
include required("../tls/mtls-admin-api.conf")
include required("../tls/tls-ledger-api.conf")
canton {
  remote-participants.participant {
    ledger-api {
      address = localhost
      address = ${?REMOTE_ADDRESS}
      port = 10001
      port = ${?LEDGER_API_PORT}
      tls = ${?_shared.ledger-api-client-tls}
    }
    admin-api {
      address = localhost
      address = ${?REMOTE_ADDRESS}
      port = 10002
      port = ${?ADMIN_API_PORT}
      tls = ${?_shared.admin-api-client-mtls}
    }
  }
}
```

Given a remote config file, start a local Canton console configured to execute commands on a remote Canton instance like this:

```
./bin/canton -c config/remote-participant1.conf
```

Additionally, you can use the remote configuration to run a script:

```
./bin/canton run <some-canton-script> -c config/remote-participant1.conf
```

Note that most Canton commands can be executed from a remote console. However, a few commands can only be called from the local console of the node itself.

Given a participant's config file, you can generate a skeleton remote config file using the `generate` command:

```
./bin/canton generate remote-config -c participant1.conf
```

Depending on your network, you might need to manually edit the auto-generated configuration to adjust the hostname. To access multiple remote nodes, consolidate the auto-generated configurations into a single remote configuration file or include all configuration files on the command line:

```
./bin/canton -c participant1.conf,participant2.conf,mydomain.conf
```

28.2.1.1 TLS and Authorization

For production use cases, in particular if the Admin API is not just bound to localhost, we recommend to enable [TLS](#) with mutual authentication. If an API is secured using certificates that are signed by a system-wide trusted CA and the TLS configuration is otherwise empty, TLS can be enabled for a remote node as following:

```
canton.remote-domains.mydomain.<api>.tls.enabled = true
```

The remote console can be used in installations that utilize authorization, so long as it has a valid access token. This can be achieved by modifying the configuration or by adding an option to the remote console's launch command as in the following snippet:

```
./bin/canton daemon \  
  -c remote-participant1.conf \  
  -C canton.remote-participants.<remote-participant-name>.token=""<encoded-and-signed-access-token-as-string>"" \  
  --bootstrap <some-script>
```

The remote console uses the token in its interactions with the ledger API of the target participant. It also extracts the user ID from the token and uses it to populate the `applicationId` field in the command submission and completion subscription requests. This affects the following console commands:

- ledger_api.commands.submit
- ledger_api.commands.submit_flat
- ledger_api.commands.submit_async
- ledger_api.completions.list
- ledger_api.completions.list_with_checkpoint
- ledger_api.completions.subscribe

Note: If you want to know more about the authorization please read the following article about the [authorization tokens](#)

28.2.2 Node References

To issue the command on a particular node, you must refer to it via its reference, which is a Scala variable. Named variables are created for all sync domain entities and participants using their configured identifiers. For example, the sample `examples/01-simple-topology/simple-topology.conf` configuration file references the sync domain `mydomain`, and participants `participant1` and `participant2`. These are available in the console as `mydomain`, `participant1` and `participant2`.

The console also provides additional generic references that allow you to consult a list of nodes by type. The generic node reference supports three subsets of each node type: local, remote or all nodes of that type. For the participants, you can use:

```
participants.local
participants.remote
participants.all
```

The generic node references can be used in a Scala syntactic way:

```
participants.all.foreach(_.dars.upload("my.dar"))
```

but the participant references also support some *generic commands* for actions that often have to be performed for many nodes at once, such as:

```
participants.local.dars.upload("my.dar")
```

The available node references are:

<console-topic-marker: Generic Node References>

28.2.3 Help

Canton can be very helpful if you ask for help. Try to type

```
help
```

or

```
participant1.help()
```

to get an overview of the commands and command groups that exist. `help()` works on every level (e.g. `participant1.domains.help()`) or can be used to search for particular functions (`help("list")`) or to get detailed help explanation for each command (`participant1.parties.help("list")`).

28.2.4 Lifecycle Operations

These are supported by individual and sequences of sync domains and participants. If called on a sequence, operations will be called sequentially in the order of the sequence. For example:

```
nodes.local.start()
```

can be used to start all configured local sync domains and participants.

If the node is running with database persistence, it will support the database migration command (`db.migrate`). The migrations are performed automatically when the node is started for the first time. However, new migrations added as part of new versions of the software must be by default run manually using the command. In some rare cases, it may also be necessary to run `db.repair_migration` before running `db.migrate` - please refer to the description of `db.repair_migration` for more details. If desired, the database migrations can be performed also automatically by enabling the `migrate-and-start` mode using the following configuration option:

```
canton.participants.participant1.storage.parameters.migrate-and-start = yes
```

Note that data continuity (and therefore database migration) is only guaranteed to work across minor and patch version updates.

The sync domain, sequencer and mediator nodes might need extra setup to be fully functional. Check [sync domain bootstrapping](#) for more details.

28.2.5 Timeouts

Console command timeouts can be configured using the respective console command timeout section in the configuration file:

```
canton.parameters.timeouts.console = {  
  bounded = 2.minutes  
  unbounded = Inf // infinity  
  ledger-command = 2.minutes  
  ping = 30.seconds  
}
```

The `bounded` argument is used for all commands that should finish once processing has completed, whereas the `unbounded` timeout is used for commands where we do not control the processing time. This is used in particular for potentially very long-running commands.

Some commands have specific timeout arguments that can be passed explicitly as type `NonNegativeDuration`. For convenience, the console includes by default the implicits of `scala.concurrent.duration._` and an implicit conversion from the Scala type `scala.concurrent.duration.FiniteDuration` to `NonNegativeDuration`. As a result, you can use [normal Scala expressions](#) and write timeouts as

```
participant1.health.ping(participant1, timeout = 10.seconds)
```

while the implicit conversion will take care of converting it to the right types.

Generally, there is no need to reconfigure the timeouts and we recommend using the safe default values.

28.2.6 Code-Generation in Console

The Daml SDK provides [code-generation utilities](#) which create **Java** or **Scala** bindings for Daml models. These bindings are a convenient way to interact with the ledger from the console in a typed fashion. The linked documentation explains how to create these bindings using the `daml` command. The **Scala** bindings are not officially supported, so should not be used for application development.

Once you have successfully built the bindings, you can then load the resulting `jar` into the Canton console using the magic **Ammonite** import trick within console scripts:

```
interp.load.cp(os.Path("codegen.jar", base = os.pwd))

@ // the at triggers the compilation such that we can use the imports subsequently

import ...
```

28.2.7 Canton Administration APIs

Canton provides the [console](#) as a builtin mode for administrative interaction. However, under the hood, all administrative console actions are effected using the administration [gRPC](#) API. Therefore, it is also possible to write your own administration application and connect it to the administration gRPC endpoints.

The `protobuf/` sub-directories in the release artifacts contain the gRPC underlying protocol buffers. In particular, the administrative gRPC APIs are located within the `admin` sub-directories.

For example, the Ping Pong Service which implements a simple workflow to smoke-test a deployment is defined with the protocol buffer `*/protobuf/*/admin/*/ping_pong_service.proto` (where `*` denotes intermediary directories). This service is then used by the console command [health.ping](#).

The protocol buffers are also available within the [repository](#) following a similar sub-directory structure as mentioned.

28.3 Console Commands

28.3.1 Top-level Commands

The following commands are available for convenience:

[exit](#)

Summary: Leave the console

[help](#)

Summary: Help with console commands; type `help(<command>)` for detailed help for `<command>`

[health.dump](#)

Summary: Generate and write a health dump of Canton's state for a bug report

Arguments:

- `outputFile`: `better.files.File`
- `timeout`: [com.digitalasset.canton.config.NonNegativeDuration](#)
- `chunkSize`: `Option[Int]`

Return type:

- String

Description: Gathers information about the current Canton process and/or remote nodes if using the console with a remote config. The `outputFile` argument can be used to write the health dump to a specific path. The `timeout` argument can be increased when retrieving large health dumps from remote nodes. The `chunkSize` argument controls the size of the byte chunks streamed back from remote nodes. This can be used if encountering errors due to gRPC max inbound message size being too low.

[health.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

[console.command_timeout](#)

Summary: Yields the timeout for running console commands

Return type:

- [com.digitalasset.canton.config.NonNegativeDuration](#)

Description: Yields the timeout for running console commands. When the timeout has elapsed, the console stops waiting for the command result. The command will continue running in the background.

[console.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

[console.set_command_timeout](#)

Summary: Sets the timeout for running console commands.

Arguments:

- `newTimeout`: [com.digitalasset.canton.config.NonNegativeDuration](#)

Description: Sets the timeout for running console commands. When the timeout has elapsed, the console stops waiting for the command result. The command will continue running in the background. The new timeout must be positive.

[logging.get_level](#)

Summary: Determine current logging level

Arguments:

- `loggerName`: String

Return type:

- `Option[ch.qos.logback.classic.Level]`

[logging.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

[logging.last_error_trace](#)

Summary: Returns log events for an error with the same trace-id

Arguments:

- `traceId`: String

Return type:

- `Seq[String]`

`logging.last_errors`

Summary: Returns the last errors (trace-id -> error event) that have been logged locally

Return type:

- `Map[String,String]`

`logging.set_level`

Summary: Dynamically change log level (TRACE, DEBUG, INFO, WARN, ERROR, OFF, null)

Arguments:

- `loggerName: String`
- `level: String`

`utils.auto_close (Testing)`

Summary: Register `AutoCloseable` object to be shutdown if Canton is shut down

Arguments:

- `closeable: AutoCloseable`

`utils.change_contracts_party_ids`

Summary: Change the party ids referenced by a sequence of contracts.

Arguments:

- `partiesOldToPartiesNew: Map[com.digitalasset.canton.topology.PartyId,com.digitalasset.canton.topology.PartyId]`
- `acs: Seq[com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrappers.WrappedCreatedEvent]`
- `domainId: com.digitalasset.canton.topology.DomainId`
- `ledgerCreateTime: java.time.Instant`
- `targetProtocolVersion: com.digitalasset.canton.version.ProtocolVersion`
- `withContractIdRemap: Boolean`

Return type:

- `Seq[com.digitalasset.canton.version.VersionedMessage[Nothing]]`

Description: The `utils.change_contracts_party_ids` changes the party ids of multiple contracts based on a map of old party ids to new party ids. This is typically used during an ACS migration when the reference party ids have changed (e.g. due to them being recreated in another participant in a different namespace). This function also requires the selection of a specific ledger create time according to the domain's clock. It is also possible to modify the domain and protocol version for those contracts, which can be useful when contracts are being migrated to a participant connected to a domain and/or protocol version. If `withContractIdRemap` is enabled, all contracts are converted to a non-authenticated form. This process involves replacing the suffix of each contract ID with the non-authenticated marker and rewriting all contract IDs accordingly.

`utils.contract_data_to_instance`

Summary: Convert contract data to a contract instance.

Arguments:

- `contractData: com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrappers.ContractData`
- `ledgerTime: java.time.Instant`

Return type:

- `com.digitalasset.canton.protocol.SerializableContract`

Description: The `utils.contract_data_to_instance` bridges the gap between `participant.ledger_api.acs` commands that return various pieces of contract data and the `participant.repair.add` command used to add contract instances as part of repair workflows. Such workflows (for example migrating contracts from other Daml ledgers to Canton participants) typically consist of extracting contract data using `participant.ledger_api.acs`

commands, modifying the contract data, and then converting the `contractData` using this function before finally adding the resulting contract instances to Canton participants via `participant.repair.add`. Obtain the `contractData` by invoking `.toContractData` on the `Wrapped-CreatedEvent` returned by the corresponding `participant.ledger_api.acs.of_party` or `of_all` call. The `ledgerTime` parameter should be chosen to be a time meaningful to the domain on which you plan to subsequently invoke `participant.repair.add` on and will be retained alongside the contract instance by the `participant.repair.add` invocation.

`utils.contract_instance_to_data`

Summary: Convert a contract instance to contract data.

Arguments:

- `contract`: [com.digitalasset.canton.protocol.SerializableContract](#)

Return type:

- [com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrappers.ContractData](#)

Description: The `utils.contract_instance_to_data` converts a Canton contract instance to contract data, a format more amenable to inspection and modification as part of repair workflows. This function consumes the output of the `participant.testing` commands and can thus be employed in workflows geared at verifying the contents of contracts for diagnostic purposes and in environments in which the `features.enable-testing-commands` configuration can be (at least temporarily) enabled.

`utils.generate_contract_id`

Summary: Generate authenticated contract id.

Arguments:

- `cryptoPureApi`: [com.digitalasset.canton.crypto.CryptoPureApi](#)
- `rawContract`: [com.digitalasset.canton.protocol.SerializableRawContractInstance](#)
- `createdAt`: [com.digitalasset.canton.data.CantonTimestamp](#)
- `discriminator`: [com.digitalasset.canton.protocol.LfHash](#)
- `contractSalt`: [com.digitalasset.canton.crypto.Salt](#)
- `metadata`: [com.digitalasset.canton.protocol.ContractMetadata](#)
- `protocolVersion`: [com.digitalasset.canton.version.ProtocolVersion](#)

Return type:

- [com.daml.lf.value.Value.ContractId.V1](#)

Description: The `utils.generate_contract_id` generates contract id of a contract. Starting from protocol version 4, Canton uses the so called authenticated contract ids which depend on the details of the associated contracts. When aspects of a contract such as the parties involved change as part of repair or export/import procedure, the corresponding contract id must be recomputed. This function can be used as a tool to generate an id for an arbitrary contract content

`utils.generate_daml_script_participants_conf`

Summary: Create a participants config for Daml script

Arguments:

- `file`: `Option[String]`
- `useParticipantAlias`: `Boolean`
- `defaultParticipant`: [Option\[com.digitalasset.canton.console.ParticipantReference\]](#)

Return type:

- `java.io.File`

Description: The generated config can be passed to `daml script` via the `participant-config` parameter. More information about the file format can be found in the [documentation](#): It

takes three arguments: - file (default to participant-config.json) - useParticipantAlias (default to true): participant aliases are used instead of UIDs - defaultParticipant (default to None): adds a default participant if provided

`utils.generate_navigator_conf`

Summary: Create a navigator ui-backend.conf for a participant

Arguments:

- participant: [com.digitalasset.canton.console.LocalParticipantReference](#)
- file: Option[String]

Return type:

- java.io.File

`utils.help`

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

`utils.migrate_dars`

Summary: Migrates dars from one participant to another.

Arguments:

- participantOld: [com.digitalasset.canton.console.ParticipantReference](#)
- participantNew: [com.digitalasset.canton.console.ParticipantReference](#)

Description: The `utils.migrate_dars` copies all dars (not part of the AdminWorkflows) from a participant, saves them in a temporary file and then uploads them to another participant.

`utils.object_args`

Summary: Reflective inspection of object arguments, handy to inspect case class objects

Arguments:

- obj: T

Return type:

- List[String]

Description: Return the list field names of the given object. Helpful function when inspecting the return result.

`utils.read_all_messages_from_file`

Summary: Reads several Protobuf messages from a file.

Arguments:

- fileName: String

Return type:

- Seq[A]

Description: Fails with an exception, if the file can't be read or parsed.

`utils.read_byte_string_from_file`

Summary: Reads a ByteString from a file.

Arguments:

- fileName: String

Return type:

- com.google.protobuf.ByteString

Description: Fails with an exception, if the file can't be read.

`utils.read_first_message_from_file`

Summary: Reads a single Protobuf message from a file.

Arguments:

- fileName: String

Return type:

- A

Description: Fails with an exception, if the file can't be read or parsed.

`utils.recompute_contract_ids`

Summary: Recompute authenticated contract ids.

Arguments:

- participant: [com.digitalasset.canton.console.LocalParticipantReference](#)
- acs: [Seq\[com.digitalasset.canton.protocol.SerializableContract\]](#)
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)

Return type:

- (Seq[com.digitalasset.canton.protocol.SerializableContract], Map[com.digitalasset.canton.protocol.LfContractId, com.digitalasset.canton.protocol.LfContractId])

Description: The `utils.recompute_contract_ids` regenerates contract ids of multiple contracts after their contents have changed. Starting from protocol version 4, Canton uses the so called authenticated contract ids which depend on the details of the associated contracts. When aspects of a contract such as the parties involved change as part of repair or export/import procedure, the corresponding contract id must be recomputed.

`utils.retry_until_true`

Summary: Wait for a condition to become true

Arguments:

- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)
- maxWaitPeriod: [com.digitalasset.canton.config.NonNegativeDuration](#)
- condition: => Boolean
- failure: => String

Return type:

- (condition: => Boolean, failure: => String): Unit

Description: Wait *timeout* duration until *condition* becomes true. Retry evaluating *condition* with an exponentially increasing back-off up to *maxWaitPeriod* duration between retries.

`utils.retry_until_true`

Summary: Wait for a condition to become true, using default timeouts

Arguments:

- condition: => Boolean

Description: Wait until condition becomes true, with a timeout taken from the parameters.timeouts.console.bounded configuration parameter.

`utils.synchronize_topology`

Summary: Wait until all topology changes have been effected on all accessible nodes

Arguments:

- timeout0: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

`utils.type_args`

Summary: Reflective inspection of type arguments, handy to inspect case class types

Return type:

- List[String]

Description: Return the list of field names of the given type. Helpful function when creating new objects for requests.

`utils.write_to_file`

Summary: Writes a ByteString to a file.

Arguments:

- data: com.google.protobuf.ByteString

- fileName: String

`utils.write_to_file`

Summary: Writes a Protobuf message to a file.

Arguments:

- data: `scalapb.GeneratedMessage`
- fileName: String

`utils.write_to_file`

Summary: Writes several Protobuf messages to a file.

Arguments:

- data: `Seq[scalapb.GeneratedMessage]`
- fileName: String

`ledger_api_utils.create (Testing)`

Summary: Build create command

Arguments:

- packageId: String
- module: String
- template: String
- arguments: `Map[String,Any]`

Return type:

- `com.daml.ledger.api.v1.commands.Command`

`ledger_api_utils.exercise (Testing)`

Summary: Build exercise command from `CreatedEvent`

Arguments:

- choice: String
- arguments: `Map[String,Any]`
- event: `com.daml.ledger.api.v1.event.CreatedEvent`

Return type:

- `com.daml.ledger.api.v1.commands.Command`

`ledger_api_utils.exercise (Testing)`

Summary: Build exercise command

Arguments:

- packageId: String
- module: String
- template: String
- choice: String
- arguments: `Map[String,Any]`
- contractId: String

Return type:

- `com.daml.ledger.api.v1.commands.Command`

`ledger_api_utils.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

28.3.2 Participant Commands

`clear_cache` (Testing)

Summary: Clear locally cached variables

Description: Some commands cache values on the client side. Use this command to explicitly clear the caches of these values.

`config`

Summary: Return participant config

Return type:

- `com.digitalasset.canton.participant.config.LocalParticipantConfig`

`help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: `String`

`id`

Summary: Yields the globally unique id of this participant. Throws an exception, if the id has not yet been allocated (e.g., the participant has not yet been started).

Return type:

- `com.digitalasset.canton.topology.ParticipantId`

`is_initialized`

Summary: Check if the local instance is running and is fully initialized

Return type:

- `Boolean`

`is_running`

Summary: Check if the local instance is running

Return type:

- `Boolean`

`start`

Summary: Start the instance

`stop`

Summary: Stop the instance

`testing.acs_search` (Testing)

Summary: Lookup of active contracts

Arguments:

- `domainAlias`: `com.digitalasset.canton.DomainAlias`
- `filterId`: `String`
- `filterPackage`: `String`
- `filterTemplate`: `String`
- `filterStakeholder`: `Option[com.digitalasset.canton.topology.PartyId]`
- `limit`: `com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- `List[com.digitalasset.canton.protocol.SerializableContract]`

`testing.await_domain_time` (Testing)

Summary: Await for the given time to be reached on the given domain

Arguments:

- `domainId`: `com.digitalasset.canton.topology.DomainId`

- time: [com.digitalasset.canton.data.CantonTimestamp](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)

[testing.await_domain_time \(Testing\)](#)

Summary: Await for the given time to be reached on the given domain

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)
- time: [com.digitalasset.canton.data.CantonTimestamp](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)

[testing.bong \(Testing\)](#)

Summary: Send a bong to a set of target parties over the ledger. Levels > 0 leads to an exploding ping with exponential number of contracts. Throw a RuntimeException in case of failure.

Arguments:

- targets: [Set\[com.digitalasset.canton.topology.ParticipantId\]](#)
- validators: [Set\[com.digitalasset.canton.topology.ParticipantId\]](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)
- levels: Long
- gracePeriodMillis: Long
- workflowId: String
- id: String

Return type:

- [scala.concurrent.duration.Duration](#)

Description: Initiates a racy ping to multiple participants, measuring the roundtrip time of the fastest responder, with an optional timeout. Grace-period is the time the bong will wait for a duplicate spent (which would indicate an error in the system) before exiting. If levels > 0, the ping command will lead to a binary explosion and subsequent dilation of contracts, where `level` determines the number of levels we will explode. As a result, the system will create $(2^{(L+2)} - 3)$ contracts (where `L` stands for `level`). Normally, only the initiator is a validator. Additional validators can be added using the `validators` argument. The bong command comes handy to run a burst test against the system and quickly leads to an overloading state.

[testing.crypto_api \(Testing\)](#)

Summary: Return the sync crypto api provider, which provides access to all cryptographic methods

Return type:

- [com.digitalasset.canton.crypto.SyncCryptoApiProvider](#)

[testing.event_search \(Testing\)](#)

Summary: Lookup of events

Arguments:

- domain: [Option\[com.digitalasset.canton.DomainAlias\]](#)
- from: [Option\[java.time.Instant\]](#)
- to: [Option\[java.time.Instant\]](#)
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[\(String, com.digitalasset.canton.participant.sync.TimestampedEvent\)\]](#)

Description: Show the event logs. To select only events from a particular domain, use the domain alias. Leave the domain empty to search the combined event log containing the events of all domains. Note that if the domain is left blank, the values of *from* and *to* cannot be set. This is because the combined event log isn't guaranteed to have increasing

timestamps.

`testing.fetch_domain_time` (Testing)

Summary: Fetch the current time from the given domain

Arguments:

- domainId: `com.digitalasset.canton.topology.DomainId`
- timeout: `com.digitalasset.canton.config.NonNegativeDuration`

Return type:

- `com.digitalasset.canton.data.CantonTimestamp`

`testing.fetch_domain_time` (Testing)

Summary: Fetch the current time from the given domain

Arguments:

- domainAlias: `com.digitalasset.canton.DomainAlias`
- timeout: `com.digitalasset.canton.config.NonNegativeDuration`

Return type:

- `com.digitalasset.canton.data.CantonTimestamp`

`testing.fetch_domain_times` (Testing)

Summary: Fetch the current time from all connected domains

Arguments:

- timeout: `com.digitalasset.canton.config.NonNegativeDuration`

`testing.find_clean_commitments_timestamp` (Testing)

Summary: The latest timestamp before or at the given one for which no commitment is outstanding

Arguments:

- domain: `com.digitalasset.canton.DomainAlias`
- beforeOrAt: `com.digitalasset.canton.data.CantonTimestamp`

Return type:

- `Option[com.digitalasset.canton.data.CantonTimestamp]`

Description: The latest timestamp before or at the given one for which no commitment is outstanding. Note that this doesn't imply that pruning is possible at this timestamp, as the system might require some additional data for crash recovery. Thus, this is useful for testing commitments; use the commands in the pruning group for pruning. Additionally, the result needn't fall on a `commitment tick` as specified by the reconciliation interval.

`testing.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

`testing.maybe_bong` (Testing)

Summary: Like `bong`, but returns `None` in case of failure.

Arguments:

- targets: `Set[com.digitalasset.canton.topology.ParticipantId]`
- validators: `Set[com.digitalasset.canton.topology.ParticipantId]`
- timeout: `com.digitalasset.canton.config.NonNegativeDuration`
- levels: `Long`
- gracePeriodMillis: `Long`
- workflowId: `String`
- id: `String`

Return type:

- Option[scala.concurrent.duration.Duration]

testing.pcs_search (Testing)

Summary: Lookup contracts in the Private Contract Store

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)
- filterId: String
- filterPackage: String
- filterTemplate: String
- activeSet: Boolean
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- List[(Boolean, com.digitalasset.canton.protocol.SerializableContract)]

Description: Get raw access to the PCS of the given domain sync controller. The filter commands will check if the target value contains the given string. The arguments can be started with ^ such that startsWith is used for comparison or ! to use equals. The activeSet argument allows to restrict the search to the active contract set.

testing.sequencer_messages (Testing)

Summary: Retrieve all sequencer messages

Arguments:

- domain: [com.digitalasset.canton.DomainAlias](#)
- from: Option[java.time.Instant]
- to: Option[java.time.Instant]
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- Seq[com.digitalasset.canton.sequencing.PossiblyIgnoredProtocolEvent]

Description: Optionally allows filtering for sequencer from a certain time span (inclusive on both ends) and limiting the number of displayed messages. The returned messages will be ordered on most domain ledger implementations if a time span is given. Fails if the participant has never connected to the domain.

testing.state_inspection (Testing)

Summary: Obtain access to the state inspection interface. Use at your own risk.

Return type:

- [com.digitalasset.canton.participant.admin.inspection.SyncStateInspection](#)

Description: The state inspection methods can fatally and permanently corrupt the state of a participant. The API is subject to change in any way.

testing.transaction_search (Testing)

Summary: Lookup of accepted transactions

Arguments:

- domain: Option[com.digitalasset.canton.DomainAlias]
- from: Option[java.time.Instant]
- to: Option[java.time.Instant]
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- Seq[(String, com.digitalasset.canton.protocol.LfCommittedTransaction)]

Description: Show the accepted transactions as they appear in the event logs. To select only transactions from a particular domain, use the domain alias. Leave the domain empty to search the combined event log containing the events of all domains. Note that if the domain is left blank, the values of from and to cannot be set. This is because the combined event log isn't guaranteed to have increasing timestamps.

28.3.2.1 Database

`db.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`db.migrate`

Summary: Migrates the instance's database if using a database storage

Description: When instances reside on different nodes, their database migration can be run in parallel to save time. Please note that the migration commands must however must be run on each node individually, because remote migration through `participants.remote` is not supported.

`db.repair_migration`

Summary: Only use when advised - repairs the database migration of the instance's database

Arguments:

- `force`: Boolean

Description: In some rare cases, we change already applied database migration files in a new release and the repair command resets the checksums we use to ensure that in general already applied migration files have not been changed. You should only use `db.repair_migration` when advised and otherwise use it at your own risk - in the worst case running it may lead to data corruption when an incompatible database migration (one that should be rejected because the already applied database migration files have changed) is subsequently falsely applied.

28.3.2.2 Health

`health.active`

Summary: Check if the node is running and is the active instance (mediator, participant)

Return type:

- Boolean

`health.count_in_flight`

Summary: Counts pending command submissions and transactions on a domain.

Arguments:

- `domainAlias`: [com.digitalasset.canton.DomainAlias](#)

Return type:

- [com.digitalasset.canton.admin.api.client.data.InFlightCount](#)

Description: This command finds the current number of pending command submissions and transactions on a selected domain. There is no synchronization between pending command submissions and transactions. And the respective counts are an indication only! This command is in particular useful to re-assure oneself that there are currently no in-flight submissions or transactions present for the selected domain. Such re-assurance is then helpful to proceed with repair operations, for example.

`health.dump`

Summary: Creates a zip file containing diagnostic information about the canton process running this node

Arguments:

- outputFile: `better.files.File`
- timeout: `com.digitalasset.canton.config.NonNegativeDuration`
- chunkSize: `Option[Int]`

Return type:

- `String`

health.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

health.initialized

Summary: Returns true if node has been initialized.

Return type:

- `Boolean`

health.last_error_trace

Summary: Show all messages logged with the given traceId in a recent interval

Arguments:

- `traceId: String`

Return type:

- `Seq[String]`

Description: Returns a list of buffered log messages associated to a given trace-id. Usually, the trace-id is taken from `last_errors()`

health.last_errors

Summary: Show the last errors logged

Return type:

- `Map[String,String]`

Description: Returns a map with the trace-id as key and the most recent error messages as value. Requires that `-log-last-errors` is enabled (and not turned off).

health.maybe_ping (Testing)

Summary: Sends a ping to the target participant over the ledger. Yields `Some(duration)` in case of success and `None` in case of failure.

Arguments:

- `participantId: com.digitalasset.canton.topology.ParticipantId`
- `timeout: com.digitalasset.canton.config.NonNegativeDuration`
- `workflowId: String`
- `id: String`

Return type:

- `Option[scala.concurrent.duration.Duration]`

health.ping

Summary: Sends a ping to the target participant over the ledger. Yields the duration in case of success and throws a `RuntimeException` in case of failure.

Arguments:

- `participantId: com.digitalasset.canton.topology.ParticipantId`
- `timeout: com.digitalasset.canton.config.NonNegativeDuration`
- `workflowId: String`
- `id: String`

Return type:

- `scala.concurrent.duration.Duration`

`health.running`

Summary: Check if the node is running

Return type:

- Boolean

`health.set_log_level`

Summary: Change the log level of the process

Arguments:

- `level`: `ch.qos.logback.classic.Level`

Description: If the default logback configuration is used, this will change the log level of the process.

`health.status`

Summary: Get human (and machine) readable participant status information

Return type:

- `com.digitalasset.canton.admin.api.client.data.NodeStatus[S]`

`health.wait_for_identity`

Summary: Wait for the node to have an identity

Description: This is specifically useful for the Domain Manager which needs its identity to be ready for bootstrapping, but for which we can't rely on `wait_for_initialized()` because it will be initialized only after being bootstrapped.

`health.wait_for_initialized`

Summary: Wait for the node to be initialized

`health.wait_for_running`

Summary: Wait for the node to be running

28.3.2.3 Domain Connectivity

`domains.accept_agreement`

Summary: Accept the service agreement of the given domain alias

Arguments:

- `domainAlias`: `com.digitalasset.canton.DomainAlias`
- `agreementId`: `String`

`domains.active`

Summary: Test whether a participant is connected to and permissioned on a domain reference, both from the perspective of the participant and the domain.

Arguments:

- `reference`: `com.digitalasset.canton.console.commands.DomainAdministration`

Return type:

- Boolean

Description: Yields false, if the domain has not been initialized, is not connected or is not healthy.

`domains.active`

Summary: Test whether a participant is connected to and permissioned on a domain.

Arguments:

- `domainAlias`: `com.digitalasset.canton.DomainAlias`

Return type:

- Boolean

Description: Yields false, if the domain is not connected or not healthy. Yields false, if the domain is configured in the Canton configuration and the participant is not active from the perspective of the domain.

`domains.config`

Summary: Returns the current configuration of a given domain

Arguments:

- domain: `com.digitalasset.canton.DomainAlias`

Return type:

- `Option[com.digitalasset.canton.participant.domain.DomainConnectionConfig]`

`domains.connect`

Summary: Macro to connect a participant to a domain given by connection

Arguments:

- domainAlias: `com.digitalasset.canton.DomainAlias`
- connection: `String`
- manualConnect: `Boolean`
- domainId: `Option[com.digitalasset.canton.topology.DomainId]`
- certificatesPath: `String`
- priority: `Int`
- timeTrackerConfig: `com.digitalasset.canton.config.DomainTimeTrackerConfig`
- synchronize: `Option[com.digitalasset.canton.config.NonNegativeDuration]`

Return type:

- `com.digitalasset.canton.participant.domain.DomainConnectionConfig`

Description: The connect macro performs a series of commands in order to connect this participant to a domain. First, *register* will be invoked with the given arguments, but first registered with `manualConnect = true`. If you already set `manualConnect = true`, then nothing else will happen and you will have to do the remaining steps yourselves. Otherwise, if the domain requires an agreement, it is fetched and presented to the user for evaluation. If the user is fine with it, the agreement is confirmed. If you want to auto-confirm, then set the environment variable `CANTON_AUTO_APPROVE_AGREEMENTS=yes`. Finally, the command will invoke *reconnect* to startup the connection. If the reconnect succeeded, the registered configuration will be updated with `manualStart = true`. If anything fails, the domain will remain registered with `manualConnect = true` and you will have to perform these steps manually. The arguments are: `domainAlias` - The name you will be using to refer to this domain. Can not be changed anymore. `connection` - The connection string to connect to this domain. I.e. <https://url:port> `manualConnect` - Whether this connection should be handled manually and also excluded from automatic re-connect. `domainId` - Optionally the domainId you expect to see on this domain. `certificatesPath` - Path to TLS certificate files to use as a trust anchor. `priority` - The priority of the domain. The higher the more likely a domain will be used. `timeTrackerConfig` - The configuration for the domain time tracker. `synchronize` - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

`domains.connect`

Summary: Macro to connect a participant to a domain given by connection

Arguments:

- config: `com.digitalasset.canton.participant.domain.DomainConnectionConfig`

Description: This variant of connect expects a domain connection config. Otherwise the behaviour is equivalent to the connect command with explicit arguments. If the domain is already configured, the domain connection will be attempted. If however the domain is offline, the command will fail. Generally, this macro should only be used to setup a new domain. However, for convenience, we support idempotent invocations where subsequent

calls just ensure that the participant reconnects to the domain.

`domains.connect_ha`

Summary: Deprecated macro to connect a participant to a domain that supports connecting via many endpoints

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)
- firstConnection: [com.digitalasset.canton.sequencing.SequencerConnection](#)
- additionalConnections: [com.digitalasset.canton.sequencing.SequencerConnection*](#)

Return type:

- [com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)

Description: Use the command `connect_ha` with the updated arguments list

`domains.connect_local`

Summary: Macro to connect a participant to a locally configured domain given by reference

Arguments:

- domain: [com.digitalasset.canton.console.InstanceReferenceWithSequencerConnection](#)
- manualConnect: `Boolean`
- alias: [Option\[com.digitalasset.canton.DomainAlias\]](#)
- maxRetryDelayMillis: [Option\[Long\]](#)
- priority: `Int`
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Description: The arguments are: domain - A local domain or sequencer reference manualConnect - Whether this connection should be handled manually and also excluded from automatic re-connect. alias - The name you will be using to refer to this domain. Can not be changed anymore. certificatesPath - Path to TLS certificate files to use as a trust anchor. priority - The priority of the domain. The higher the more likely a domain will be used. synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

`domains.connect_multi`

Summary: Macro to connect a participant to a domain that supports connecting via many endpoints

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)
- connections: [Seq\[com.digitalasset.canton.sequencing.SequencerConnection\]](#)
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Return type:

- [com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)

Description: Domains can provide many endpoints to connect to for availability and performance benefits. This version of connect allows specifying multiple endpoints for a single domain connection: `connect_multi(mydomain , Seq(sequencer1, sequencer2))` or: `connect_multi(mydomain , Seq(https://host1.mydomain.net , https://host2.mydomain.net , https://host3.mydomain.net))` To create a more advanced connection config use `domains.toConfig` with a single host, then use `config.addConnection` to add additional connections before connecting: `config = myparticipant.domains.toConfig(mydomain , https://host1.mydomain.net , otherArguments)` `config = config.addConnection(https://host2.mydomain.net , https://host3.mydomain.net)` `myparticipant.domains.connect(config)` The arguments are: domainAlias - The name you will be using to refer to this domain. Can not be changed anymore. connections - The sequencer

connection definitions (can be an URL) to connect to this domain. I.e. [https://url:port](#) synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

[domains.connect_single](#)

Summary: Macro to connect a participant to a domain that supports a single sequencer connection

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)
- sequencerConnection: [com.digitalasset.canton.sequencing.SequencerConnection](#)
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Return type:

- [com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)

Description: Calls a `connect_multi` macro with a single sequencer connection. This is particularly useful if we have a reference to a remote sequencer and can easily get the respective sequencer connection `<sequencer>.sequencerConnection`. The arguments are: domainAlias - The name you will be using to refer to this domain. Can not be changed anymore. sequencerConnection - A single sequencer connection to connect to this domain. I.e. [https://url:port](#) synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

[domains.disconnect](#)

Summary: Disconnect this participant from the given domain

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)

[domains.disconnect_all](#)

Summary: Disconnect this participant from all connected domains

[domains.disconnect_local](#)

Summary: Disconnect this participant from the given local domain

Arguments:

- domain: [com.digitalasset.canton.console.DomainReference](#)

[domains.get_agreement](#)

Summary: Get the service agreement of the given domain alias and if it has been accepted already.

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)

Return type:

- [Option\[\(com.digitalasset.canton.participant.admin.v0.Agreement, Boolean\)\]](#)

[domains.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

[domains.id_of](#)

Summary: Returns the id of the given domain alias

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)

Return type:

- [com.digitalasset.canton.topology.DomainId](#)

domains.is_connected

Summary: Test whether a participant is connected to a domain reference

Arguments:

- reference: [com.digitalasset.canton.console.commands.DomainAdministration](#)

Return type:

- Boolean

domains.is_registered

Summary: Returns true if a domain is registered using the given alias

Arguments:

- domain: [com.digitalasset.canton.DomainAlias](#)

Return type:

- Boolean

domains.list_connected

Summary: List the connected domains of this participant

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListConnectedDomainsResult\]](#)

domains.list_registered

Summary: List the configured active domains of this participant

Return type:

- [Seq\[\(com.digitalasset.canton.participant.domain.DomainConnectionConfig, Boolean\)\]](#)

domains.modify

Summary: Modify existing domain connection

Arguments:

- domain: [com.digitalasset.canton.DomainAlias](#)
- modifier: [com.digitalasset.canton.participant.domain.DomainConnectionConfig => com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)

domains.reconnect

Summary: Reconnect this participant to the given domain

Arguments:

- domainAlias: [com.digitalasset.canton.DomainAlias](#)
- retry: Boolean
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Return type:

- Boolean

Description: Idempotent attempts to re-establish a connection to a certain domain. If retry is set to false, the command will throw an exception if unsuccessful. If retry is set to true, the command will terminate after the first attempt with the result, but the server will keep on retrying to connect to the domain. The arguments are: domainAlias - The name you will be using to refer to this domain. Can not be changed anymore. retry - Whether the reconnect should keep on retrying until it succeeded or abort noisily if the connection attempt fails. synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

domains.reconnect_all

Summary: Reconnect this participant to all domains which are not marked as manual start

Arguments:

- ignoreFailures: Boolean

- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Description: The arguments are: ignoreFailures - If set to true (default), we'll attempt to connect to all, ignoring any failure synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

[domains.reconnect_local](#)

Summary: Reconnect this participant to the given local domain

Arguments:

- ref: [com.digitalasset.canton.console.DomainReference](#)
- retry: Boolean
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Return type:

- Boolean

Description: Idempotent attempts to re-establish a connection to the given local domain. Same behaviour as generic reconnect. The arguments are: ref - The domain reference to connect to retry - Whether the reconnect should keep on retrying until it succeeded or abort noisily if the connection attempt fails. synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

[domains.register](#)

Summary: Register new domain connection

Arguments:

- config: [com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)

Description: When connecting to a domain, we need to register the domain connection and eventually accept the terms of service of the domain before we can connect. The registration process is therefore a subset of the operation. Therefore, register is equivalent to connect if the domain does not require a service agreement. However, you would usually call register only in advanced scripts.

28.3.2.4 Packages

[packages.find](#)

Summary: Find packages that contain a module with the given name

Arguments:

- moduleName: String
- limitPackages: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.participant.admin.v0.PackageDescription\]](#)

[packages.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[packages.list](#)

Summary: List packages stored on the participant

Arguments:

- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.participant.admin.v0.PackageDescription\]](#)

Description: Supported arguments: limit - Limit on the number of packages returned (defaults to `canton.parameters.console.default-limit`)

`packages.list_contents`

Summary: List package contents

Arguments:

- `packageId`: String

Return type:

- `Seq[com.digitalasset.canton.participant.admin.v0.ModuleDescription]`

`packages.remove (Preview)`

Summary: Remove the package from Canton's package store.

Arguments:

- `packageId`: String
- `force`: Boolean

Description: The standard operation of this command checks that a package is unused and unvetted, and if so removes the package. The force flag can be used to disable the checks, but do not use the force flag unless you're certain you know what you're doing.

`packages.synchronize_vetting`

Summary: Ensure that all vetting transactions issued by this participant have been observed by all configured participants

Arguments:

- `timeout`: `com.digitalasset.canton.config.NonNegativeDuration`

Description: Sometimes, when scripting tests and demos, a dar or package is uploaded and we need to ensure that commands are only submitted once the package vetting has been observed by some other connected participant known to the console. This command can be used in such cases.

28.3.2.5 DAR Management

`dars.download`

Summary: Downloads the DAR file with the given hash to the given directory

Arguments:

- `darHash`: String
- `directory`: String

`dars.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`dars.list`

Summary: List installed DAR files

Arguments:

- `limit`: `com.digitalasset.canton.config.RequireTypes.PositiveInt`
- `filterName`: String

Return type:

- `Seq[com.digitalasset.canton.participant.admin.v0.DarDescription]`

Description: List DARs installed on this participant The arguments are: `filterName`: filter by name (source description) `limit`: Limit number of results (default none)

`dars.list_contents`

Summary: List contents of DAR files

Arguments:

- hash: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.DarMetadata](#)

dars.remove (Preview)

Summary: Remove a DAR from the participant

Arguments:

- darHash: String
- synchronizeVetting: Boolean

Description: Can be used to remove a DAR from the participant, if the following conditions are satisfied: 1. The main package of the DAR must be unused – there should be no active contract from this package 2. All package dependencies of the DAR should either be unused or contained in another of the participant node’s uploaded DARs. Canton uses this restriction to ensure that the package dependencies of the DAR don’t become stranded if they’re in use. 3. The main package of the dar should not be vetted. If it is vetted, Canton will try to automatically revoke the vetting for the main package of the DAR, but this automatic vetting revocation will only succeed if the main package vetting originates from a standard `dars.upload`. Even if the automatic revocation fails, you can always manually revoke the package vetting. If `synchronizeVetting` is true (default), then the command will block until the participant has observed the vetting transactions to be registered with the domain.

dars.upload

Summary: Upload a Dar to Canton

Arguments:

- path: String
- vetAllPackages: Boolean
- synchronizeVetting: Boolean

Return type:

- String

Description: Daml code is normally shipped as a Dar archive and must explicitly be uploaded to a participant. A Dar is a collection of LF-packages, the native binary representation of Daml smart contracts. In order to use Daml templates on a participant, the Dar must first be uploaded and then vetted by the participant. Vetting will ensure that other participants can check whether they can actually send a transaction referring to a particular Daml package and participant. Vetting is done by registering a `VettedPackages` topology transaction with the topology manager. By default, vetting happens automatically and this command waits for the vetting transaction to be successfully registered on all connected domains. This is the safe default setting minimizing race conditions. If `vetAllPackages` is true (default), the packages will all be vetted on all domains the participant is registered. If `synchronizeVetting` is true (default), then the command will block until the participant has observed the vetting transactions to be registered with the domain. If `alsoSynchronizeCheckOnly` is true (default), then the command will block until the participant has observed the check-only packages transactions on the domain. Note that `synchronize vetting` might block on permissioned domains that do not just allow participants to update the topology state. In such cases, `synchronizeVetting` should be turned off. `Synchronize vetting` can be invoked manually using `$participant.package.synchronize_vettings()`

dars.validate

Summary: Validate DARs against the current participants’ state

Arguments:

- path: String

Return type:

- String

Description: Performs the same DAR and Daml package validation checks that the upload call performs, but with no effects on the target participants: the DAR is not persisted or vetted.

28.3.2.6 Party Management

The party management commands allow to conveniently enable and disable parties on the local node. Under the hood, they use the more complicated but feature-rich identity management commands.

parties.await_topology_observed (Preview)

Summary: Waits for any topology changes to be observed

Arguments:

- partyAssignment: Set[(com.digitalasset.canton.topology.PartyId, T)]
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)

Description: Will throw an exception if the given topology has not been observed within the given timeout.

parties.disable

Summary: Disable party on participant

Arguments:

- name: [com.digitalasset.canton.topology.Identifier](#)
- force: Boolean

parties.enable

Summary: Enable/add party to participant

Arguments:

- name: String
- displayName: Option[String]
- waitForDomain: [com.digitalasset.canton.console.commands.DomainChoice](#)
- synchronizeParticipants: [Seq\[com.digitalasset.canton.console.ParticipantReference\]](#)

Return type:

- [com.digitalasset.canton.topology.PartyId](#)

Description: This function registers a new party with the current participant within the participants namespace. The function fails if the participant does not have appropriate signing keys to issue the corresponding PartyToParticipant topology transaction. Optionally, a local display name can be added. This display name will be exposed on the ledger API party management endpoint. Specifying a set of domains via the *WaitForDomain* parameter ensures that the domains have enabled/added a party by the time the call returns, but other participants connected to the same domains may not yet be aware of the party. Additionally, a sequence of additional participants can be added to be synchronized to ensure that the party is known to these participants as well before the function terminates.

parties.find

Summary: Find a party from a filter string

Arguments:

- filterParty: String

Return type:

- [com.digitalasset.canton.topology.PartyId](#)

Description: Will search for all parties that match this filter string. If it finds exactly one party, it will return that one. Otherwise, the function will throw.

`parties.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`parties.hosted`

Summary: List parties hosted by this participant

Arguments:

- `filterParty`: String
- `filterDomain`: String
- `asOf`: `Option[java.time.Instant]`
- `limit`: `com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- `Seq[com.digitalasset.canton.admin.api.client.data.ListPartiesResult]`

Description: Inspect the parties hosted by this participant as used for synchronisation. The response is built from the timestamped topology transactions of each domain, excluding the authorized store of the given node. The search will include all hosted parties and is equivalent to running the `list` method using the participant id of the invoking participant. `filterParty`: Filter by parties starting with the given string. `filterDomain`: Filter by domains whose id starts with the given string. `asOf`: Optional timestamp to inspect the topology state at a given point in time. `limit`: How many items to return (defaults to `canton.parameters.console.default-limit`) Example: `participant1.parties.hosted(filterParty= alice)`

`parties.list`

Summary: List active parties, their active participants, and the participants' permissions on domains.

Arguments:

- `filterParty`: String
- `filterParticipant`: String
- `filterDomain`: String
- `asOf`: `Option[java.time.Instant]`
- `limit`: `com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- `Seq[com.digitalasset.canton.admin.api.client.data.ListPartiesResult]`

Description: Inspect the parties known by this participant as used for synchronisation. The response is built from the timestamped topology transactions of each domain, excluding the authorized store of the given node. For each known party, the list of active participants and their permission on the domain for that party is given. `filterParty`: Filter by parties starting with the given string. `filterParticipant`: Filter for parties that are hosted by a participant with an id starting with the given string `filterDomain`: Filter by domains whose id starts with the given string. `asOf`: Optional timestamp to inspect the topology state at a given point in time. `limit`: Limit on the number of parties fetched (defaults to `canton.parameters.console.default-limit`). Example: `participant1.parties.list(filterParty= alice)`

`parties.set_display_name`

Summary: Set party display name

Arguments:

- party: [com.digitalasset.canton.topology.PartyId](#)
- displayName: String

Description: Locally set the party display name (shown on the ledger-api) to the given value

[parties.update](#)

Summary: Update participant-local party details

Arguments:

- party: [com.digitalasset.canton.topology.PartyId](#)
- modifier: [com.digitalasset.canton.admin.api.client.data.PartyDetails](#) => [com.digitalasset.canton.admin.api.client.data.PartyDetails](#)

Return type:

- [com.digitalasset.canton.admin.api.client.data.PartyDetails](#)

Description: Currently you can update only the annotations. You cannot update other user attributes. party: party to be updated, modifier: a function to modify the party details, e.g.: `partyDetails => { partyDetails.copy(annotations = partyDetails.annotations.updated(a , b).removed(c)) }`

28.3.2.7 Key Administration

[keys.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

[keys.public.download](#)

Summary: Download public key

Arguments:

- fingerprint: [com.digitalasset.canton.crypto.Fingerprint](#)
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)

Return type:

- [com.google.protobuf.ByteString](#)

[keys.public.download_to](#)

Summary: Download public key and save it to a file

Arguments:

- fingerprint: [com.digitalasset.canton.crypto.Fingerprint](#)
- outputFile: String
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)

[keys.public.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

[keys.public.list](#)

Summary: List public keys in registry

Arguments:

- filterFingerprint: String
- filterContext: String

Return type:

- Seq[com.digitalasset.canton.crypto.PublicKeyWithName]

Description: Returns all public keys that have been added to the key registry. Optional arguments can be used for filtering.

keys.public.list_by_owner

Summary: List keys for given keyOwner.

Arguments:

- keyOwner: com.digitalasset.canton.topology.KeyOwner
- filterDomain: String
- asOf: Option[java.time.Instant]
- limit: com.digitalasset.canton.config.RequireTypes.PositiveInt

Return type:

- Seq[com.digitalasset.canton.admin.api.client.data.ListKeyOwnersResult]

Description: This command is a convenience wrapper for `list_key_owners`, taking an explicit keyOwner as search argument. The response includes the public keys.

keys.public.list_owners

Summary: List active owners with keys for given search arguments.

Arguments:

- filterKeyOwnerUid: String
- filterKeyOwnerType: Option[com.digitalasset.canton.topology.KeyOwner-Code]
- filterDomain: String
- asOf: Option[java.time.Instant]
- limit: com.digitalasset.canton.config.RequireTypes.PositiveInt

Return type:

- Seq[com.digitalasset.canton.admin.api.client.data.ListKeyOwnersResult]

Description: This command allows deep inspection of the topology state. The response includes the public keys. Optional filterKeyOwnerType type can be 'ParticipantId.Code', 'MediatorId.Code', 'SequencerId.Code', 'DomainTopologyManagerId.Code'.

keys.public.upload

Summary: Upload public key

Arguments:

- filename: String
- name: Option[String]

Return type:

- com.digitalasset.canton.crypto.Fingerprint

keys.public.upload

Summary: Upload public key

Arguments:

- keyBytes: com.google.protobuf.ByteString
- name: Option[String]

Return type:

- com.digitalasset.canton.crypto.Fingerprint

Description: Import a public key and store it together with a name used to provide some context to that key.

keys.secret.delete

Summary: Delete private key

Arguments:

- fingerprint: com.digitalasset.canton.crypto.Fingerprint
- force: Boolean

`keys.secret.download`

Summary: Download key pair

Arguments:

- fingerprint: `com.digitalasset.canton.crypto.Fingerprint`
- protocolVersion: `com.digitalasset.canton.version.ProtocolVersion`

Return type:

- `com.google.protobuf.ByteString`

`keys.secret.download_to`

Summary: Download key pair and save it to a file

Arguments:

- fingerprint: `com.digitalasset.canton.crypto.Fingerprint`
- outputFile: `String`
- protocolVersion: `com.digitalasset.canton.version.ProtocolVersion`

`keys.secret.generate_encryption_key`

Summary: Generate new public/private key pair for encryption and store it in the vault

Arguments:

- name: `String`
- scheme: `Option[com.digitalasset.canton.crypto.EncryptionKeyScheme]`

Return type:

- `com.digitalasset.canton.crypto.EncryptionPublicKey`

Description: The optional name argument allows you to store an associated string for your convenience. The scheme can be used to select a key scheme and the default scheme is used if left unspecified.

`keys.secret.generate_signing_key`

Summary: Generate new public/private key pair for signing and store it in the vault

Arguments:

- name: `String`
- scheme: `Option[com.digitalasset.canton.crypto.SigningKeyScheme]`

Return type:

- `com.digitalasset.canton.crypto.SigningPublicKey`

Description: The optional name argument allows you to store an associated string for your convenience. The scheme can be used to select a key scheme and the default scheme is used if left unspecified.

`keys.secret.get_wrapper_key_id`

Summary: Get the wrapper key id that is used for the encrypted private keys store

Return type:

- `String`

`keys.secret.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

`keys.secret.list`

Summary: List keys in private vault

Arguments:

- filterFingerprint: `String`
- filterName: `String`
- purpose: `Set[com.digitalasset.canton.crypto.KeyPurpose]`

Return type:

- [Seq\[com.digitalasset.canton.crypto.admin.grpc.PrivateKeyMetadata\]](#)

Description: Returns all public keys to the corresponding private keys in the key vault. Optional arguments can be used for filtering.

[keys.secret.register_kms_encryption_key](#)

Summary: Register the specified KMS encryption key in canton storing its public information in the vault

Arguments:

- kmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.EncryptionPublicKey](#)

Description: The id for the KMS encryption key. The optional name argument allows you to store an associated string for your convenience.

[keys.secret.register_kms_signing_key](#)

Summary: Register the specified KMS signing key in canton storing its public information in the vault

Arguments:

- kmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.SigningPublicKey](#)

Description: The id for the KMS signing key. The optional name argument allows you to store an associated string for your convenience.

[keys.secret.rotate_kms_node_key](#)

Summary: Rotate a given node's keypair with a new pre-generated KMS keypair

Arguments:

- fingerprint: String
- newKmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates an existing encryption or signing key stored externally in a KMS with a pre-generated key. For a sequencer or mediator node use `rotate_kms_node_key` with a domain manager reference as an argument. The fingerprint of the key we want to rotate. The id of the new KMS key (e.g. Resource Name). An optional name for the new key.

[keys.secret.rotate_node_key](#)

Summary: Rotate a node's public/private key pair

Arguments:

- fingerprint: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates an existing encryption or signing key. NOTE: A namespace root or intermediate signing key CANNOT be rotated by this command. For a sequencer or mediator node use `rotate_kms_node_key` with a domain manager reference as an argument. The fingerprint of the key we want to rotate. An optional name for the new key.

[keys.secret.rotate_node_keys](#)

Summary: Rotate the node's public/private key pairs

Description: For a participant node it rotates the signing and encryption key pair. For a domain or domain manager node it rotates the signing key pair as those nodes do not have an encryption key pair. For a sequencer or mediator node use `rotate_node_keys` with a domain manager reference as an argument. NOTE: Namespace root or intermediate signing keys are NOT rotated by this command.

`keys.secret.rotate_wrapper_key`

Summary: Change the wrapper key for encrypted private keys store

Arguments:

- `newWrapperKeyId`: String

Description: Change the wrapper key (e.g. AWS KMS key) being used to encrypt the private keys in the store. `newWrapperKeyId`: The optional new wrapper key id to be used. If the wrapper key id is empty Canton will generate a new key based on the current configuration.

`keys.secret.upload`

Summary: Upload a key pair

Arguments:

- `pairBytes`: `com.google.protobuf.ByteString`
- `name`: `Option[String]`

`keys.secret.upload`

Summary: Upload (load and import) a key pair from file

Arguments:

- `filename`: String
- `name`: `Option[String]`

28.3.2.8 Topology Administration

The topology commands can be used to manipulate and inspect the topology state. In all commands, we use fingerprints to refer to public keys. Internally, these fingerprints are resolved using the key registry (which is a map of Fingerprint -> PublicKey). Any key can be added to the key registry using the `keys.public.load` commands.

`topology.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`topology.init_id`

Summary: Initialize the node with a unique identifier

Arguments:

- `identifier`: `com.digitalasset.canton.topology.Identifier`
- `fingerprint`: `com.digitalasset.canton.crypto.Fingerprint`

Return type:

- `com.digitalasset.canton.topology.UniqueIdentifier`

Description: Every node in Canton is identified using a unique identifier, which is composed of a user-chosen string and the fingerprint of a signing key. The signing key is the root key defining a so-called namespace, where the signing key has the ultimate control over issuing new identifiers. During initialisation, we have to pick such a unique identifier. By default, initialisation happens automatically, but it can be turned off by setting the `auto-init` option to false. Automatic node initialisation is usually turned off to preserve the identity of a participant or domain node (during major version upgrades) or if the topology

transactions are managed through a different topology manager than the one integrated into this node.

`topology.load_transaction`

Summary: Upload signed topology transaction

Arguments:

- bytes: `com.google.protobuf.ByteString`

Description: Topology transactions can be issued with any topology manager. In some cases, such transactions need to be copied manually between nodes. This function allows for uploading previously exported topology transaction into the authorized store (which is the name of the topology managers transaction store).

`topology.stores.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

`topology.stores.list`

Summary: List available topology stores

Return type:

- `Seq[String]`

Description: Topology transactions are stored in these stores. There are the following stores:

- `Authorized` - The authorized store is the store of a topology manager. Updates to the topology state are made by adding new transactions to the `Authorized` store. Both the participant and the domain nodes topology manager have such a store. A participant node will distribute all the content in the `Authorized` store to the domains it is connected to. The domain node will distribute the content of the `Authorized` store through the sequencer to the domain members in order to create the authoritative topology state on a domain (which is stored in the store named using the domain-id), such that every domain member will have the same view on the topology state on a particular domain.

- `<domain-id>` - The domain store is the authorized topology state on a domain. A participant has one store for each domain it is connected to. The domain has exactly one store with its domain-id.
- `Requested` - A domain can be configured such that when participant tries to register a topology transaction with the domain, the transaction is placed into the `Requested` store such that it can be analysed and processed with user defined process.

`topology.namespace_delegations.authorize`

Summary: Change namespace delegation

Arguments:

- ops: `com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- namespace: `com.digitalasset.canton.crypto.Fingerprint`
- authorizedKey: `com.digitalasset.canton.crypto.Fingerprint`
- isRootDelegation: `Boolean`
- signedBy: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- synchronize: `Option[com.digitalasset.canton.config.NonNegativeDuration]`
- force: `Boolean`

Return type:

- `com.google.protobuf.ByteString`

Description: Delegates the authority to authorize topology transactions in a certain namespace to a certain key. The keys are referred to using their fingerprints. They need to be either locally generated or have been previously imported. ops: Either Add or Remove the delegation. namespace: The namespace whose authorization authority is delegated.

signedBy: Optional fingerprint of the authorizing key. The authorizing key needs to be either the **authorizedKey** for root certificates. Otherwise, the **signedBy** key needs to refer to a previously authorized key, which means that we use the **signedBy** key to refer to a locally available CA. **authorizedKey:** Fingerprint of the key to be authorized. If **signedBy** equals **authorizedKey**, then this transaction corresponds to a self-signed root certificate. If the keys differ, then we get an intermediate CA. **isRootDelegation:** If set to true (default = false), the authorized key will be allowed to issue **NamespaceDelegations**. **synchronize:** Synchronize timeout can be used to ensure that the state has been propagated into the node

[topology.namespace_delegations.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName:` String

[topology.namespace_delegations.list](#)

Summary: List namespace delegation transactions

Arguments:

- `filterStore:` String
- `useStateStore:` Boolean
- `timeQuery:` [com.digitalasset.canton.topology.store.TimeQuery](#)
- `operation:` [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- `filterNamespace:` String
- `filterSigningKey:` String
- `filterTargetKey:` [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- `protocolVersion:` [Option\[String\]](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListNamespaceDelegationResult\]](#)

Description: List the namespace delegation transaction present in the stores. Namespace delegations are topology transactions that permission a key to issue topology transactions within a certain namespace. **filterStore:** Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) **useStateStore:** If true (default), only properly authorized transactions that are part of the state will be selected. **timeQuery:** The time query allows to customize the query by time. The following options are supported: **TimeQuery.HeadState** (default): The most recent known state. **TimeQuery.Snapshot(ts):** The state at a certain point in time. **TimeQuery.Range(fromO, toO):** Time-range of when the transaction was added to the store **operation:** Optionally, what type of operation the transaction should have. State store only has `Add`. **filterSigningKey:** Filter for transactions that are authorized with a key that starts with the given filter string. **filterNamespace:** Filter for namespaces starting with the given filter string. **filterTargetKey:** Filter for namespaces delegations for the given target key. **protocolVersion:** Export the topology transactions in the optional protocol version.

[topology.identifier_delegations.authorize](#)

Summary: Change identifier delegation

Arguments:

- `ops:` [com.digitalasset.canton.topology.transaction.TopologyChangeOp](#)
- `identifier:` [com.digitalasset.canton.topology.UniqueIdentifier](#)
- `authorizedKey:` [com.digitalasset.canton.crypto.Fingerprint](#)
- `signedBy:` [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- `synchronize:` [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Return type:

- `com.google.protobuf.ByteString`

Description: Delegates the authority of a certain identifier to a certain key. This corresponds to a normal certificate which binds identifier to a key. The keys are referred to using their fingerprints. They need to be either locally generated or have been previously imported. ops: Either Add or Remove the delegation. signedBy: Refers to the optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. authorizedKey: Fingerprint of the key to be authorized. synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

[`topology.identifier_delegations.help`](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

[`topology.identifier_delegations.list`](#)

Summary: List identifier delegation transactions

Arguments:

- `filterStore: String`
- `useStateStore: Boolean`
- `timeQuery: com.digitalasset.canton.topology.store.TimeQuery`
- `operation: Option[com.digitalasset.canton.topology.transaction.TopologyChangeOp]`
- `filterUid: String`
- `filterSigningKey: String`
- `filterTargetKey: Option[com.digitalasset.canton.crypto.Fingerprint]`
- `protocolVersion: Option[String]`

Return type:

- `Seq[com.digitalasset.canton.admin.api.client.data.ListIdentifierDelegationResult]`

Description: List the identifier delegation transaction present in the stores. Identifier delegations are topology transactions that permission a key to issue topology transactions for a certain unique identifier. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add. filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterUid: Filter for unique identifiers starting with the given filter string. protocolVersion: Export the topology transactions in the optional protocol version.

[`topology.owner_to_key_mappings.authorize`](#)

Summary: Change an owner to key mapping

Arguments:

- `ops: com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- `keyOwner: com.digitalasset.canton.topology.KeyOwner`
- `key: com.digitalasset.canton.crypto.Fingerprint`
- `purpose: com.digitalasset.canton.crypto.KeyPurpose`
- `signedBy: Option[com.digitalasset.canton.crypto.Fingerprint]`

- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)
- force: Boolean

Return type:

- com.google.protobuf.ByteString

Description: Change a owner to key mapping. A key owner is anyone in the system that needs a key-pair known to all members (participants, mediator, sequencer, topology manager) of a domain. ops: Either Add or Remove the key mapping update. signedBy: Optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. ownerType: Role of the following owner (Participant, Sequencer, Mediator, Domain-TopologyManager) owner: Unique identifier of the owner. key: Fingerprint of key purposes: The purposes of the owner to key mapping. force: removing the last key is dangerous and must therefore be manually forced synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

[topology.owner_to_key_mappings.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[topology.owner_to_key_mappings.list](#)

Summary: List owner to key mapping transactions

Arguments:

- filterStore: String
- useStateStore: Boolean
- timeQuery: [com.digitalasset.canton.topology.store.TimeQuery](#)
- operation: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- filterKeyOwnerType: [Option\[com.digitalasset.canton.topology.KeyOwnerCode\]](#)
- filterKeyOwnerUid: String
- filterKeyPurpose: [Option\[com.digitalasset.canton.crypto.KeyPurpose\]](#)
- filterSigningKey: String
- protocolVersion: Option[String]

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListOwnerToKeyMappingResult\]](#)

Description: List the owner to key mapping transactions present in the stores. Owner to key mappings are topology transactions defining that a certain key is used by a certain key owner. Key owners are participants, sequencers, mediators and domains. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add . filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterKeyOwnerType: Filter for a particular type of key owner (KeyOwnerCode). filterKeyOwnerUid: Filter for key owners unique identifier starting with the given filter string. filterKeyPurpose: Filter for keys with a particular purpose (Encryption or Signing) protocolVersion: Export the topology transactions in the optional protocol

version.

`topology.owner_to_key_mappings.rotate_key`

Summary: Rotate the key for an owner to key mapping

Arguments:

- nodeInstance: `com.digitalasset.canton.console.InstanceReferenceCommon`
- owner: `com.digitalasset.canton.topology.KeyOwner`
- currentKey: `com.digitalasset.canton.crypto.PublicKey`
- newKey: `com.digitalasset.canton.crypto.PublicKey`

Description: Rotates the key for an existing owner to key mapping by issuing a new owner to key mapping with the new key and removing the previous owner to key mapping with the previous key. nodeInstance: The node instance that is used to verify that both current and new key pertain to this node. This avoids conflicts when there are different nodes with the same uuid (i.e., multiple sequencers). owner: The owner of the owner to key mapping currentKey: The current public key that will be rotated newKey: The new public key that has been generated

`topology.party_to_participant_mappings.authorize (Preview)`

Summary: Change party to participant mapping

Arguments:

- ops: `com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- party: `com.digitalasset.canton.topology.PartyId`
- participant: `com.digitalasset.canton.topology.ParticipantId`
- side: `com.digitalasset.canton.topology.transaction.RequestSide`
- permission: `com.digitalasset.canton.topology.transaction.ParticipantPermission`
- signedBy: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- synchronize: `Option[com.digitalasset.canton.config.NonNegativeDuration]`
- replaceExisting: `Boolean`
- force: `Boolean`

Return type:

- `com.google.protobuf.ByteString`

Description: Change the association of a party to a participant. If both identifiers are in the same namespace, then the request-side is Both. If they differ, then we need to say whether the request comes from the party (`RequestSide.From`) or from the participant (`RequestSide.To`). And, we need the matching request of the other side. Please note that this is a preview feature due to the fact that inhomogeneous topologies can not yet be properly represented on the Ledger API. ops: Either Add or Remove the mapping signedBy: Refers to the optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. party: The unique identifier of the party we want to map to a participant. participant: The unique identifier of the participant to which the party is supposed to be mapped. side: The request side (`RequestSide.From` if we the transaction is from the perspective of the party, `RequestSide.To` from the participant.) privilege: The privilege of the given participant which allows us to restrict an association (e.g. Confirmation or Observation). replaceExisting: If true (default), replace any existing mapping with the new setting synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

`topology.party_to_participant_mappings.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

`topology.party_to_participant_mappings.list`

Summary: List party to participant mapping transactions

Arguments:

- `filterStore`: String
- `useStateStore`: Boolean
- `timeQuery`: [com.digitalasset.canton.topology.store.TimeQuery](#)
- `operation`: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- `filterParty`: String
- `filterParticipant`: String
- `filterRequestSide`: [Option\[com.digitalasset.canton.topology.transaction.RequestSide\]](#)
- `filterPermission`: [Option\[com.digitalasset.canton.topology.transaction.ParticipantPermission\]](#)
- `filterSigningKey`: String
- `protocolVersion`: [Option\[String\]](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListPartyToParticipantResult\]](#)

Description: List the party to participant mapping transactions present in the stores. Party to participant mappings are topology transactions used to allocate a party to a certain participant. The same party can be allocated on several participants with different privileges. A party to participant mapping has a request-side that identifies whether the mapping is authorized by the party, by the participant or by both. In order to have a party be allocated to a given participant, we therefore need either two transactions (one with `RequestSide.From`, one with `RequestSide.To`) or one with `RequestSide.Both`. `filterStore`: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) `useStateStore`: If true (default), only properly authorized transactions that are part of the state will be selected. `timeQuery`: The time query allows to customize the query by time. The following options are supported: `TimeQuery.HeadState` (default): The most recent known state. `TimeQuery.Snapshot(ts)`: The state at a certain point in time. `TimeQuery.Range(fromO, toO)`: Time-range of when the transaction was added to the store `operation`: Optionally, what type of operation the transaction should have. State store only has `Add`. `filterSigningKey`: Filter for transactions that are authorized with a key that starts with the given filter string. `filterParty`: Filter for parties starting with the given filter string. `filterParticipant`: Filter for participants starting with the given filter string. `filterRequestSide`: Optional filter for a particular request side (Both, From, To). `protocolVersion`: Export the topology transactions in the optional protocol version.

`topology.participant_domain_states.active`

Summary: Returns true if the given participant is currently active on the given domain

Arguments:

- `domainId`: [com.digitalasset.canton.topology.DomainId](#)
- `participantId`: [com.digitalasset.canton.topology.ParticipantId](#)

Return type:

- Boolean

Description: Active means that the participant has been granted at least observation rights on the domain and that the participant has registered a domain trust certificate

`topology.participant_domain_states.authorize`

Summary: Change participant domain states

Arguments:

- `ops`: [com.digitalasset.canton.topology.transaction.TopologyChangeOp](#)

- domain: [com.digitalasset.canton.topology.DomainId](#)
- participant: [com.digitalasset.canton.topology.ParticipantId](#)
- side: [com.digitalasset.canton.topology.transaction.RequestSide](#)
- permission: [com.digitalasset.canton.topology.transaction.ParticipantPermission](#)
- trustLevel: [com.digitalasset.canton.topology.transaction.TrustLevel](#)
- signedBy: [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)
- replaceExisting: Boolean

Return type:

- [com.google.protobuf.ByteString](#)

Description: Change the association of a participant to a domain. In order to activate a participant on a domain, we need both authorisation: the participant authorising its uid to be present on a particular domain and the domain to authorise the presence of a participant on said domain. If both identifiers are in the same namespace, then the request-side can be Both. If they differ, then we need to say whether the request comes from the domain (RequestSide.From) or from the participant (RequestSide.To). And, we need the matching request of the other side. ops: Either Add or Remove the mapping signedBy: Refers to the optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. domain: The unique identifier of the domain we want the participant to join. participant: The unique identifier of the participant. side: The request side (RequestSide.From if we the transaction is from the perspective of the domain, RequestSide.To from the participant.) permission: The privilege of the given participant which allows us to restrict an association (e.g. Confirmation or Observation). Will use the lower of if different between To/From. trustLevel: The trust level of the participant on the given domain. Will use the lower of if different between To/From. replaceExisting: If true (default), replace any existing mapping with the new setting synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

[topology.participant_domain_states.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[topology.participant_domain_states.list](#)

Summary: List participant domain states

Arguments:

- filterStore: String
- useStateStore: Boolean
- timeQuery: [com.digitalasset.canton.topology.store.TimeQuery](#)
- operation: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- filterDomain: String
- filterParticipant: String
- filterSigningKey: String
- protocolVersion: [Option\[String\]](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListParticipantDomainStateResult\]](#)

Description: List the participant domain transactions present in the stores. Participant domain states are topology transactions used to permission a participant on a given do-

main. A participant domain state has a request-side that identifies whether the mapping is authorized by the participant (From), by the domain (To) or by both (Both). In order to use a participant on a domain, both have to authorize such a mapping. This means that by authorizing such a topology transaction, a participant acknowledges its presence on a domain, whereas a domain permissions the participant on that domain. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add . filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterDomain: Filter for domains starting with the given filter string. filterParticipant: Filter for participants starting with the given filter string. protocolVersion: Export the topology transactions in the optional protocol version.

`topology.vetted_packages.authorize`

Summary: Change package vettings

Arguments:

- ops: `com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- participant: `com.digitalasset.canton.topology.ParticipantId`
- packageIds: `Seq[com.daml.lf.data.Ref.PackageId]`
- signedBy: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- synchronize: `Option[com.digitalasset.canton.config.NonNegativeDuration]`
- force: `Boolean`

Return type:

- `com.google.protobuf.ByteString`

Description: A participant will only process transactions that reference packages that all involved participants have vetted previously. Vetting is done by registering a respective topology transaction with the domain, which can then be used by other participants to verify that a transaction is only using vetted packages. Note that all referenced and dependent packages must exist in the package store. By default, only vetting transactions adding new packages can be issued. Removing package vettings and issuing package vettings for other participants (if their identity is controlled through this participants topology manager) or for packages that do not exist locally can only be run using the `force = true` flag. However, these operations are dangerous and can lead to the situation of a participant being unable to process transactions. ops: Either Add or Remove the vetting. participant: The unique identifier of the participant that is vetting the package. packageIds: The lf-package ids to be vetted. signedBy: Refers to the fingerprint of the authorizing key which in turn must be authorized by a valid, locally existing certificate. If none is given, a key is automatically determined. synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node force: Flag to enable dangerous operations (default false). Great power requires great care.

`topology.vetted_packages.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

`topology.vetted_packages.list`

Summary: List package vetting transactions

Arguments:

- filterStore: String
- useStateStore: Boolean
- timeQuery: [com.digitalasset.canton.topology.store.TimeQuery](#)
- operation: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- filterParticipant: String
- filterSigningKey: String
- protocolVersion: Option[String]

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListVettedPackagesResult\]](#)

Description: List the package vetting transactions present in the stores. Participants must vet Daml packages and submitters must ensure that the receiving participants have vetted the package prior to submitting a transaction (done automatically during submission and validation). Vetting is done by authorizing such topology transactions and registering with a domain. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add . filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterParticipant: Filter for participants starting with the given filter string. protocolVersion: Export the topology transactions in the optional protocol version.

[topology.all.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[topology.all.list](#)

Summary: List all transaction

Arguments:

- filterStore: String
- useStateStore: Boolean
- timeQuery: [com.digitalasset.canton.topology.store.TimeQuery](#)
- operation: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- filterAuthorizedKey: [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- protocolVersion: Option[String]

Return type:

- [com.digitalasset.canton.topology.store.StoredTopologyTransactions\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)

Description: List all topology transactions in a store, independent of the particular type. This method is useful for exporting entire states. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. Time-

Query.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add . filterAuthorizedKey: Filter the topology transactions by the key that has authorized the transactions. protocolVersion: Export the topology transactions in the optional protocol version.

`topology.all.renew`

Summary: Renew all topology transactions that have been authorized with a previous key using a new key

Arguments:

- filterAuthorizedKey: [com.digitalasset.canton.crypto.Fingerprint](#)
- authorizeWith: [com.digitalasset.canton.crypto.Fingerprint](#)

Description: Finds all topology transactions that have been authorized by *filterAuthorizedKey* and renews those topology transactions by authorizing them with the new key *authorizeWith*. *filterAuthorizedKey*: Filter the topology transactions by the key that has authorized the transactions. *authorizeWith*: The key to authorize the renewed topology transactions.

28.3.2.9 Ledger API Access

The following commands on a participant reference provide access to the participant's Ledger API services.

`ledger_api.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

Transaction Service

`ledger_api.transactions.by_id (Testing)`

Summary: Get a (tree) transaction by its ID

Arguments:

- `parties`: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- `id`: String

Return type:

- [Option\[com.daml.ledger.api.v1.transaction.TransactionTree\]](#)

Description: Get a transaction tree from the transaction stream by its ID. Returns `None` if the transaction is not (yet) known at the participant or if the transaction has been pruned via `pruning.prune`.

`ledger_api.transactions.domain_of (Testing)`

Summary: Get the domain that a transaction was committed over.

Arguments:

- `transactionId`: String

Return type:

- [com.digitalasset.canton.topology.DomainId](#)

Description: Get the domain that a transaction was committed over. Throws an error if the transaction is not (yet) known to the participant or if the transaction has been pruned via `pruning.prune`.

ledger_api.transactions.end (Testing)**Summary:** Get ledger end**Return type:**

- `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`

ledger_api.transactions.flat (Testing)**Summary:** Get flat transactions**Arguments:**

- `partyIds`: `Set[com.digitalasset.canton.topology.PartyId]`
- `completeAfter`: `Int`
- `beginOffset`: `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`
- `endOffset`: `Option[com.daml.ledger.api.v1.ledger_offset.LedgerOffset]`
- `verbose`: `Boolean`
- `timeout`: `com.digitalasset.canton.config.NonNegativeDuration`

Return type:

- `Seq[com.daml.ledger.api.v1.transaction.Transaction]`

Description: This function connects to the flat transaction stream for the given parties and collects transactions until either *completeAfter* transaction trees have been received or *timeout* has elapsed. The returned transactions can be filtered to be between the given offsets (default: no filtering). If the participant has been pruned via *pruning.prune* and if *beginOffset* is lower than the pruning offset, this command fails with a *NOT_FOUND* error. If you need to specify filtering conditions for template IDs and including create event blobs for explicit disclosure, consider using *ledger_api.transactions.flat_with_tx_filter*.

ledger_api.transactions.flat_with_tx_filter (Testing)**Summary:** Get flat transactions**Arguments:**

- `filter`: `com.daml.ledger.api.v1.transaction_filter.TransactionFilter`
- `completeAfter`: `Int`
- `beginOffset`: `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`
- `endOffset`: `Option[com.daml.ledger.api.v1.ledger_offset.LedgerOffset]`
- `verbose`: `Boolean`
- `timeout`: `com.digitalasset.canton.config.NonNegativeDuration`

Return type:

- `Seq[com.daml.ledger.api.v1.transaction.Transaction]`

Description: This function connects to the flat transaction stream for the given transaction filter and collects transactions until either *completeAfter* transactions have been received or *timeout* has elapsed. The returned transactions can be filtered to be between the given offsets (default: no filtering). If the participant has been pruned via *pruning.prune* and if *beginOffset* is lower than the pruning offset, this command fails with a *NOT_FOUND* error. If you only need to filter by a set of parties, consider using *ledger_api.transactions.flat* instead.

ledger_api.transactions.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: `String`

ledger_api.transactions.start_measuring (Testing)**Summary:** Starts measuring throughput at the transaction service**Arguments:**

- `parties`: `Set[com.digitalasset.canton.topology.PartyId]`

- `metricSuffix`: `String`
- `onTransaction`: `com.daml.ledger.api.v1.transaction.TransactionTree => Unit`

Return type:

- `AutoCloseable`

Description: This function will subscribe on behalf of *parties* to the transaction tree stream and notify various metrics: The metric `<name>.<metricSuffix>` counts the number of transaction trees emitted. The metric `<name>.<metricSuffix>-tx-node-count` tracks the number of root events emitted as part of transaction trees. The metric `<name>.<metricSuffix>-tx-size` tracks the number of bytes emitted as part of transaction trees. To stop measuring, you need to close the returned `AutoCloseable`. Use the `onTransaction` parameter to register a callback that is called on every transaction tree.

`ledger_api.transactions.subscribe_flat` (Testing)

Summary: Subscribe to the flat transaction stream

Arguments:

- `observer`: `io.grpc.stub.StreamObserver[com.daml.ledger.api.v1.transaction.Transaction]`
- `filter`: `com.daml.ledger.api.v1.transaction_filter.TransactionFilter`
- `beginOffset`: `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`
- `endOffset`: `Option[com.daml.ledger.api.v1.ledger_offset.LedgerOffset]`
- `verbose`: `Boolean`

Return type:

- `AutoCloseable`

Description: This function connects to the flat transaction stream and passes transactions to *observer* until the stream is completed. Only transactions for parties in *filter.filterByParty.keys* will be returned. Use *filter = TransactionFilter(Map(myParty.toLf -> Filters()))* to return all transactions for *myParty*: *PartyId*. The returned transactions can be filtered to be between the given offsets (default: no filtering). If the participant has been pruned via *pruning.prune* and if *beginOffset* is lower than the pruning offset, this command fails with a `NOT_FOUND` error.

`ledger_api.transactions.subscribe_trees` (Testing)

Summary: Subscribe to the transaction tree stream

Arguments:

- `observer`: `io.grpc.stub.StreamObserver[com.daml.ledger.api.v1.transaction.TransactionTree]`
- `filter`: `com.daml.ledger.api.v1.transaction_filter.TransactionFilter`
- `beginOffset`: `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`
- `endOffset`: `Option[com.daml.ledger.api.v1.ledger_offset.LedgerOffset]`
- `verbose`: `Boolean`

Return type:

- `AutoCloseable`

Description: This function connects to the transaction tree stream and passes transaction trees to *observer* until the stream is completed. Only transaction trees for parties in *filter.filterByParty.keys* will be returned. Use *filter = TransactionFilter(Map(myParty.toLf -> Filters()))* to return all trees for *myParty*: *PartyId*. The returned transactions can be filtered to be between the given offsets (default: no filtering). If the participant has been pruned via *pruning.prune* and if *beginOffset* is lower than the pruning offset, this command fails with a `NOT_FOUND` error.

`ledger_api.transactions.trees` (Testing)

Summary: Get transaction trees

Arguments:

- partyIds: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- completeAfter: Int
- beginOffset: [com.daml.ledger.api.v1.ledger_offset.LedgerOffset](#)
- endOffset: [Option\[com.daml.ledger.api.v1.ledger_offset.LedgerOffset\]](#)
- verbose: Boolean
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)

Return type:

- [Seq\[com.daml.ledger.api.v1.transaction.TransactionTree\]](#)

Description: This function connects to the transaction tree stream for the given parties and collects transaction trees until either *completeAfter* transaction trees have been received or *timeout* has elapsed. The returned transaction trees can be filtered to be between the given offsets (default: no filtering). If the participant has been pruned via *pruning.prune* and if *beginOffset* is lower than the pruning offset, this command fails with a *NOT_FOUND* error.

Command Service

[ledger_api.commands.failed \(Testing\)](#)

Summary: Investigate failed commands

Arguments:

- commandId: String
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.platform.apiserver.execution.CommandStatus\]](#)

Description: Same as `status(, state = CommandState.Failed)`.

[ledger_api.commands.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

[ledger_api.commands.status \(Testing\)](#)

Summary: Investigate successful and failed commands

Arguments:

- commandIdPrefix: String
- state: [com.daml.ledger.api.v1.admin.command_inspection_service.CommandState](#)
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.platform.apiserver.execution.CommandStatus\]](#)

Description: Find the status of commands. Note that only recent commands which are kept in memory will be returned.

[ledger_api.commands.submit \(Testing\)](#)

Summary: Submit command and wait for the resulting transaction, returning the transaction tree or failing otherwise

Arguments:

- actAs: [Seq\[com.digitalasset.canton.topology.PartyId\]](#)
- commands: [Seq\[com.daml.ledger.api.v1.commands.Command\]](#)
- workflowId: String
- commandId: String

- optTimeout: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)
- deduplicationPeriod: [Option\[com.digitalasset.canton.ledger.api.DeduplicationPeriod\]](#)
- submissionId: String
- minLedgerTimeAbs: Option[java.time.Instant]
- readAs: [Seq\[com.digitalasset.canton.topology.PartyId\]](#)
- disclosedContracts: Seq[com.daml.ledger.api.v1.commands.DisclosedContract]
- applicationId: String
- userPackageSelectionPreference: Seq[com.digitalasset.canton.LfPackageId]

Return type:

- com.daml.ledger.api.v1.transaction.TransactionTree

Description: Submits a command on behalf of the actAs parties, waits for the resulting transaction to commit and returns it. If the timeout is set, it also waits for the transaction to appear at all other configured participants who were involved in the transaction. The call blocks until the transaction commits or fails; the timeout only specifies how long to wait at the other participants. Fails if the transaction doesn't commit, or if it doesn't become visible to the involved participants in the allotted time. Note that if the optTimeout is set and the involved parties are concurrently enabled/disabled or their participants are connected/disconnected, the command may currently result in spurious timeouts or may return before the transaction appears at all the involved participants.

[ledger_api.commands.submit_async \(Testing\)](#)

Summary: Submit command asynchronously

Arguments:

- actAs: [Seq\[com.digitalasset.canton.topology.PartyId\]](#)
- commands: Seq[com.daml.ledger.api.v1.commands.Command]
- workflowId: String
- commandId: String
- deduplicationPeriod: [Option\[com.digitalasset.canton.ledger.api.DeduplicationPeriod\]](#)
- submissionId: String
- minLedgerTimeAbs: Option[java.time.Instant]
- readAs: [Seq\[com.digitalasset.canton.topology.PartyId\]](#)
- disclosedContracts: Seq[com.daml.ledger.api.v1.commands.DisclosedContract]
- applicationId: String
- userPackageSelectionPreference: Seq[com.digitalasset.canton.LfPackageId]

Description: Provides access to the command submission service of the Ledger API. See <https://docs.daml.com/app-dev/services.html> for documentation of the parameters.

[ledger_api.commands.submit_flat \(Testing\)](#)

Summary: Submit command and wait for the resulting transaction, returning the flattened transaction or failing otherwise

Arguments:

- actAs: [Seq\[com.digitalasset.canton.topology.PartyId\]](#)
- commands: Seq[com.daml.ledger.api.v1.commands.Command]
- workflowId: String
- commandId: String
- optTimeout: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

- deduplicationPeriod: [Option\[com.digitalasset.canton.ledger.api.DeduplicationPeriod\]](#)
- submissionId: `String`
- minLedgerTimeAbs: `Option[java.time.Instant]`
- readAs: [Seq\[com.digitalasset.canton.topology.PartyId\]](#)
- disclosedContracts: `Seq[com.daml.ledger.api.v1.commands.DisclosedContract]`
- applicationId: `String`
- userPackageSelectionPreference: `Seq[com.digitalasset.canton.LfPackageId]`

Return type:

- `com.daml.ledger.api.v1.transaction.Transaction`

Description: Submits a command on behalf of the actAs parties, waits for the resulting transaction to commit, and returns the flattened transaction. If the timeout is set, it also waits for the transaction to appear at all other configured participants who were involved in the transaction. The call blocks until the transaction commits or fails; the timeout only specifies how long to wait at the other participants. Fails if the transaction doesn't commit, or if it doesn't become visible to the involved participants in the allotted time. Note that if the optTimeout is set and the involved parties are concurrently enabled/disabled or their participants are connected/disconnected, the command may currently result in spurious timeouts or may return before the transaction appears at all the involved participants.

Command Completion Service

[ledger_api.completions.end \(Testing\)](#)

Summary: Read the current command completion offset

Return type:

- `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`

[ledger_api.completions.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

[ledger_api.completions.list \(Testing\)](#)

Summary: Lists command completions following the specified offset

Arguments:

- `partyId: com.digitalasset.canton.topology.PartyId`
- `atLeastNumCompletions: Int`
- `offset: com.daml.ledger.api.v1.ledger_offset.LedgerOffset`
- `applicationId: String`
- `timeout: com.digitalasset.canton.config.NonNegativeDuration`
- `filter: com.daml.ledger.api.v1.completion.Completion => Boolean`

Return type:

- `Seq[com.daml.ledger.api.v1.completion.Completion]`

Description: If the participant has been pruned via *pruning.prune* and if *offset* is lower than the pruning offset, this command fails with a *NOT_FOUND* error.

[ledger_api.completions.list_with_checkpoint \(Testing\)](#)

Summary: Lists command completions following the specified offset along with the checkpoints included in the completions

Arguments:

- partyId: [com.digitalasset.canton.topology.PartyId](#)
- atLeastNumCompletions: Int
- offset: [com.daml.ledger.api.v1.ledger_offset.LedgerOffset](#)
- applicationId: String
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)
- filter: [com.daml.ledger.api.v1.completion.Completion](#) => Boolean

Return type:

- Seq[([com.daml.ledger.api.v1.completion.Completion](#), [com.daml.ledger.api.v1.command_completion_service.Checkpoint](#))] Option

Description: If the participant has been pruned via *pruning.prune* and if *offset* is lower than the pruning offset, this command fails with a *NOT_FOUND* error.

[ledger_api.completions.subscribe \(Testing\)](#)

Summary: Subscribe to the command completion stream

Arguments:

- observer: [io.grpc.stub.StreamObserver](#)[[com.daml.ledger.api.v1.completion.Completion](#)]
- parties: Seq[[com.digitalasset.canton.topology.PartyId](#)]
- beginOffset: [com.daml.ledger.api.v1.ledger_offset.LedgerOffset](#)
- applicationId: String

Return type:

- [AutoCloseable](#)

Description: This function connects to the command completion stream and passes command completions to *observer* until the stream is completed. Only completions for parties in *parties* will be returned. The returned completions start at *beginOffset* (default: *LEDGER_BEGIN*). If the participant has been pruned via *pruning.prune* and if *beginOffset* is lower than the pruning offset, this command fails with a *NOT_FOUND* error.

Active Contract Service

[ledger_api.acs.await_active_contract \(Testing\)](#)

Summary: Wait until the party sees the given contract in the active contract service

Arguments:

- party: [com.digitalasset.canton.topology.PartyId](#)
- contractId: [com.digitalasset.canton.protocol.LfContractId](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)

Description: Will throw an exception if the contract is not found to be active within the given timeout

[ledger_api.acs.find_generic \(Testing\)](#)

Summary: Generic search for contracts

Arguments:

- partyId: [com.digitalasset.canton.topology.PartyId](#)
- filter: [com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrappers.WrappedCreatedEvent](#) => Boolean
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)

Return type:

- [com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrap-](#)

[pers.WrappedCreatedEvent](#)

Description: This search function returns an untyped ledger-api event. The find will wait until the contract appears or throw an exception once it times out.

[ledger_api.acs.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[ledger_api.acs.of_all \(Testing\)](#)

Summary: List the set of active contracts for all parties hosted on this participant

Arguments:

- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)
- verbose: Boolean
- filterTemplates: [Seq\[com.digitalasset.canton.admin.api.client.data.TemplateId\]](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)
- identityProviderId: String
- includeCreatedEventBlob: Boolean

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrappers.WrappedCreatedEvent\]](#)

Description: This command will return the current set of active contracts for all parties. Supported arguments: - limit: limit (default set via `canton.parameter.console`) - verbose: whether the resulting events should contain detailed type information - filterTemplate: list of templates ids to filter for, empty sequence acts as a wildcard - timeout: the maximum wait time for the complete acs to arrive - identityProviderId: limit the response to parties governed by the given identity provider - includeCreatedEventBlob: whether the result should contain the createdEventBlobs, it works only if the filterTemplate is non-empty

[ledger_api.acs.of_party \(Testing\)](#)

Summary: List the set of active contracts of a given party

Arguments:

- party: [com.digitalasset.canton.topology.PartyId](#)
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)
- verbose: Boolean
- filterTemplates: [Seq\[com.digitalasset.canton.admin.api.client.data.TemplateId\]](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)
- includeCreatedEventBlob: Boolean

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.commands.LedgerApiTypeWrappers.WrappedCreatedEvent\]](#)

Description: This command will return the current set of active contracts for the given party. Supported arguments: - party: for which party you want to load the acs - limit: limit (default set via `canton.parameter.console`) - verbose: whether the resulting events should contain detailed type information - filterTemplate: list of templates ids to filter for, empty sequence acts as a wildcard - timeout: the maximum wait time for the complete acs to arrive - includeCreatedEventBlob: whether the result should contain the createdEventBlobs, it works only if the filterTemplate is non-empty

Package Service

`ledger_api.packages.check_upgrade_validity`

Summary: Check a participant's Daml packages for upgrade validity

Description: Checks the upgradable Daml packages (compiled with LF 1.17) persisted on the participant for upgrade validity. It is recommended to run this check for all participants upgrading from Canton 2.10.0, before the upgrade procedure is started. If you are upgrading from older Canton versions (2.9.x and older) to Canton 2.10.1+, this check is not necessary. This command will fail if some packages in the participant's package store are not upgrade-compatible. Note: This command does not upload or modify any packages on the participant.

`ledger_api.packages.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`ledger_api.packages.list (Testing)`

Summary: List Daml Packages

Arguments:

- `limit`: `com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- `Seq[com.daml.ledger.api.v1.admin.package_management_service.PackageDetails]`

`ledger_api.packages.upload_dar (Testing)`

Summary: Upload packages from Dar file

Arguments:

- `darPath`: String

Description: Uploading the Dar can be done either through the ledger Api server or through the Canton admin Api. The Ledger Api is the portable method across ledgers. The Canton admin Api is more powerful as it allows for controlling Canton specific behaviour. In particular, a Dar uploaded using the ledger Api will not be available in the Dar store and can not be downloaded again. Additionally, Dars uploaded using the ledger Api will be vetted, but the system will not wait for the Dars to be successfully registered with all connected domains. As such, if a Dar is uploaded and then used immediately thereafter, a command might bounce due to missing package vettings.

`ledger_api.packages.validate_dar (Testing)`

Summary: Validate a DAR against the current participants' state

Arguments:

- `darPath`: String

Description: Performs the same DAR and Daml package validation checks that the upload call performs, but with no effects on the target participants: the DAR is not persisted or vetted.

Party Management Service

`ledger_api.parties.allocate` (Testing)

Summary: Allocate a new party

Arguments:

- party: String
- displayName: String
- annotations: Map[String,String]
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.PartyDetails](#)

Description: Allocates a new party on the ledger. party: a hint for generating the party identifier displayName: a human-readable name of this party annotations: key-value pairs associated with this party and stored locally on this Ledger API server identityProviderId: identity provider id

`ledger_api.parties.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

`ledger_api.parties.list` (Testing)

Summary: List parties known by the Ledger API server

Arguments:

- identityProviderId: String

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.PartyDetails\]](#)

Description: Lists parties known by the Ledger API server. identityProviderId: identity provider id

`ledger_api.parties.update`

Summary: Update participant-local party details

Arguments:

- party: [com.digitalasset.canton.topology.PartyId](#)
- modifier: [com.digitalasset.canton.admin.api.client.data.PartyDetails](#) => [com.digitalasset.canton.admin.api.client.data.PartyDetails](#)
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.PartyDetails](#)

Description: Currently you can update only the annotations. You cannot update other user attributes. party: party to be updated, modifier: a function to modify the party details, e.g.: `partyDetails => { partyDetails.copy(annotations = partyDetails.annotations.updated(a , b).removed(c)) }` identityProviderId: identity provider id

`ledger_api.parties.update_idp` (Testing)

Summary: Update party's identity provider id

Arguments:

- party: [com.digitalasset.canton.topology.PartyId](#)
- sourceIdentityProviderId: String
- targetIdentityProviderId: String

Description: Updates party's identity provider id. party: party to be updated sourceIdentityProviderId: source identity provider id targetIdentityProviderId: target identity provider

id

Ledger Configuration Service

ledger_api.configuration.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

ledger_api.configuration.list (Testing)

Summary: Obtain the ledger configuration

Arguments:

- `expectedConfigs`: Int
- `timeout`: [com.digitalasset.canton.config.NonNegativeDuration](#)

Return type:

- `Seq[com.daml.ledger.api.v1.ledger_configuration_service.LedgerConfiguration]`

Description: Returns the current ledger configuration and subsequent updates until the expected number of configs was retrieved or the timeout is over.

Ledger Api User Management Service

ledger_api.users.create (Testing)

Summary: Create a user with the given id

Arguments:

- `id`: String
- `actAs`: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- `primaryParty`: [Option\[com.digitalasset.canton.topology.PartyId\]](#)
- `readAs`: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- `participantAdmin`: Boolean
- `isActive`: Boolean
- `annotations`: [Map\[String,String\]](#)
- `identityProviderId`: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.User](#)

Description: Users are used to dynamically managing the rights given to Daml applications. They allow us to link a stable local identifier (of an application) with a set of parties. `id`: the id used to identify the given user `actAs`: the set of parties this user is allowed to act as `primaryParty`: the optional party that should be linked to this user by default `readAs`: the set of parties this user is allowed to read as `participantAdmin`: flag (default false) indicating if the user is allowed to use the admin commands of the Ledger Api `isActive`: flag (default true) indicating if the user is active `annotations`: the set of key-value pairs linked to this user `identityProviderId`: identity provider id

ledger_api.users.delete (Testing)

Summary: Delete a user

Arguments:

- `id`: String
- `identityProviderId`: String

Description: Delete a user by id. `id`: user id `identityProviderId`: identity provider id

ledger_api.users.get (Testing)

Summary: Get the user data of the user with the given id

Arguments:

- id: String
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.User](#)

Description: Fetch the data associated with the given user id failing if there is no such user. You will get the user's primary party, active status and annotations. If you need the user rights, use rights.list instead. id: user id identityProviderId: identity provider id

ledger_api.users.help

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

ledger_api.users.list (Testing)

Summary: List users

Arguments:

- filterUser: String
- pageToken: String
- pageSize: Int
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.UsersPage](#)

Description: List users of this participant node filterUser: filter results using the given filter string pageToken: used for pagination (the result contains a page token if there are further pages) pageSize: default page size before the filter is applied identityProviderId: identity provider id

ledger_api.users.update (Testing)

Summary: Update a user

Arguments:

- id: String
- modifier: [com.digitalasset.canton.admin.api.client.data.User](#) => [com.digitalasset.canton.admin.api.client.data.User](#)
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.User](#)

Description: Currently you can update the annotations, active status and primary party. You cannot update other user attributes. id: id of the user to be updated modifier: a function for modifying the user; e.g: user => { user.copy(isActive = false, primaryParty = None, annotations = user.annotations.updated(a , b).removed(c))} identityProviderId: identity provider id

ledger_api.users.update_idp (Testing)

Summary: Update user's identity provider id

Arguments:

- id: String
- sourceIdentityProviderId: String
- targetIdentityProviderId: String

Description: Updates user's identity provider id. id: the id used to identify the given user

sourceIdentityProviderId: source identity provider id targetIdentityProviderId: target identity provider id

ledger_api.users.rights.grant (Testing)

Summary: Grant new rights to a user

Arguments:

- id: String
- actAs: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- readAs: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- participantAdmin: Boolean
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.UserRights](#)

Description: Users are used to dynamically managing the rights given to Daml applications. This function is used to grant new rights to an existing user. id: the id used to identify the given user actAs: the set of parties this user is allowed to act as readAs: the set of parties this user is allowed to read as participantAdmin: flag (default false) indicating if the user is allowed to use the admin commands of the Ledger Api identityProviderId: identity provider id

ledger_api.users.rights.help

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

ledger_api.users.rights.list (Testing)

Summary: List rights of a user

Arguments:

- id: String
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.UserRights](#)

Description: Lists the rights of a user, or the rights of the current user. id: user id identityProviderId: identity provider id

ledger_api.users.rights.revoke (Testing)

Summary: Revoke user rights

Arguments:

- id: String
- actAs: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- readAs: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- participantAdmin: Boolean
- identityProviderId: String

Return type:

- [com.digitalasset.canton.admin.api.client.data.UserRights](#)

Description: Use to revoke specific rights from a user. id: the id used to identify the given user actAs: the set of parties this user should not be allowed to act as readAs: the set of parties this user should not be allowed to read as participantAdmin: if set to true, the participant admin rights will be removed identityProviderId: identity provider id

Ledger Api Metering Service

ledger_api.metering.get_report (Testing)

Summary: Get the ledger metering report

Arguments:

- from: [com.digitalasset.canton.data.CantonTimestamp](#)
- to: [Option\[com.digitalasset.canton.data.CantonTimestamp\]](#)
- applicationId: [Option\[String\]](#)

Return type:

- [String](#)

Description: Returns the current ledger metering report from: required from timestamp (inclusive) to: optional to timestamp application_id: optional application id to which we want to restrict the report

ledger_api.metering.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: [String](#)

28.3.2.10 Composability

transfer.execute (Preview)

Summary: Transfer the contract from the origin domain to the target domain

Arguments:

- submittingParty: [com.digitalasset.canton.topology.PartyId](#)
- contractId: [com.digitalasset.canton.protocol.LfContractId](#)
- sourceDomain: [com.digitalasset.canton.DomainAlias](#)
- targetDomain: [com.digitalasset.canton.DomainAlias](#)

Description: Macro that first calls `transfer_out` and then `transfer_in`. No error handling is done.

transfer.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: [String](#)

transfer.in (Preview)

Summary: Transfer-in a contract in transit to the target domain

Arguments:

- submittingParty: [com.digitalasset.canton.topology.PartyId](#)
- transferId: [com.digitalasset.canton.protocol.TransferId](#)
- targetDomain: [com.digitalasset.canton.DomainAlias](#)
- applicationId: [com.digitalasset.canton.LedgerApplicationId](#)
- submissionId: [String](#)
- workflowId: [String](#)
- commandId: [String](#)

Description: Manually transfers a contract in transit into the target domain. The command returns when the transfer-in has completed successfully. If the `transferExclusivityTimeout` in the target domain's parameters is set to a positive value, all participants of all stakeholders connected to both origin and target domain will attempt to transfer-in the

contract automatically after the exclusivity timeout has elapsed. An application-id can be specified to uniquely identifies the application that have issued the transfer, otherwise the default value will be used. An optional submission id can be set by the committer to the value of their choice that allows an application to correlate completions to its submissions.

[transfer.lookup_contract_domain \(Preview\)](#)

Summary: Lookup the active domain for the provided contracts

Arguments:

- contractIds: [com.digitalasset.canton.protocol.LfContractId*](#)

Return type:

- Map[[com.digitalasset.canton.protocol.LfContractId](#),String]

[transfer.out \(Preview\)](#)

Summary: Transfer-out a contract from the source domain with destination target domain

Arguments:

- submittingParty: [com.digitalasset.canton.topology.PartyId](#)
- contractId: [com.digitalasset.canton.protocol.LfContractId](#)
- sourceDomain: [com.digitalasset.canton.DomainAlias](#)
- targetDomain: [com.digitalasset.canton.DomainAlias](#)
- applicationId: [com.digitalasset.canton.LedgerApplicationId](#)
- submissionId: String
- workflowId: String
- commandId: String

Return type:

- [com.digitalasset.canton.protocol.TransferId](#)

Description: Transfers the given contract out of the source domain with destination target domain. The command returns the ID of the transfer when the transfer-out has completed successfully. The contract is in transit until the transfer-in has completed on the target domain. The submitting party must be a stakeholder of the contract and the participant must have submission rights for the submitting party on the source domain. It must also be connected to the target domain. An application-id can be specified to uniquely identify the application that have issued the transfer, otherwise the default value will be used. An optional submission id can be set by the committer to the value of their choice that allows an application to correlate completions to its submissions.

[transfer.search \(Preview\)](#)

Summary: Search the currently in-flight transfers

Arguments:

- targetDomain: [com.digitalasset.canton.DomainAlias](#)
- filterSourceDomain: [Option\[com.digitalasset.canton.DomainAlias\]](#)
- filterTimestamp: [Option\[java.time.Instant\]](#)
- filterSubmittingParty: [Option\[com.digitalasset.canton.topology.PartyId\]](#)
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.participant.admin.grpc.TransferSearchResult\]](#)

Description: Returns all in-flight transfers with the given target domain that match the filters, but no more than the limit specifies.

28.3.2.11 Ledger Pruning

`pruning.clear_schedule`

Summary: Deactivate automatic pruning.

`pruning.find_safe_offset (Preview)`

Summary: Return the highest participant ledger offset whose record time is before or at the given one (if any) at which pruning is safely possible

Arguments:

- `beforeOrAt`: `java.time.Instant`

Return type:

- `Option[com.daml.ledger.api.v1.ledger_offset.LedgerOffset]`

`pruning.get_offset_by_time`

Summary: Identify the participant ledger offset to prune up to based on the specified timestamp.

Arguments:

- `upToInclusive`: `java.time.Instant`

Return type:

- `Option[com.daml.ledger.api.v1.ledger_offset.LedgerOffset]`

Description: Return the largest participant ledger offset that has been processed before or at the specified timestamp. The time is measured on the participant's local clock at some point while the participant has processed the the event. Returns `None` if no such offset exists.

`pruning.get_participant_schedule`

Summary: Inspect the automatic, participant-specific pruning schedule.

Return type:

- `Option[com.digitalasset.canton.admin.api.client.data.ParticipantPruningSchedule]`

Description: The schedule consists of a `cron` expression and `max_duration` and `retention` durations as described in the `get_schedule` command description. Additionally `prune_internally` indicates if the schedule mandates pruning of internal state.

`pruning.get_schedule`

Summary: Inspect the automatic pruning schedule.

Return type:

- `Option[com.digitalasset.canton.admin.api.client.data.PruningSchedule]`

Description: The schedule consists of a `cron` expression and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period. Returns `None` if no schedule has been configured via `set_schedule` or if `clear_schedule` has been invoked.

`pruning.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: `String`

`pruning.locate_offset (Preview)`

Summary: Identify the participant ledger offset to prune up to.

Arguments:

- `n`: Long

Return type:

- `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`

Description: Return the participant ledger offset that corresponds to pruning `n` number of transactions from the beginning of the ledger. Errors if the ledger holds less than `n` transactions. Specifying `n` of 1 returns the offset of the first transaction (if the ledger is non-empty).

`pruning.prune`

Summary: Prune the ledger up to the specified offset inclusively.

Arguments:

- `pruneUpTo`: `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`

Description: Prunes the participant ledger up to the specified offset inclusively returning `Unit` if the ledger has been successfully pruned. Note that upon successful pruning, subsequent attempts to read transactions via `ledger_api.transactions.flat` or `ledger_api.transactions.trees` or command completions via `ledger_api.completions.list` by specifying a begin offset lower than the returned pruning offset will result in a `NOT_FOUND` error. In the Enterprise Edition, `prune` performs a full prune freeing up significantly more space and also performs additional safety checks returning a `NOT_FOUND` error if `pruneUpTo` is higher than the offset returned by `find_safe_offset` on any domain with events preceding the pruning offset.

`pruning.prune_internally (Preview)`

Summary: Prune only internal ledger state up to the specified offset inclusively.

Arguments:

- `pruneUpTo`: `com.daml.ledger.api.v1.ledger_offset.LedgerOffset`

Description: Special-purpose variant of the `prune` command only available in the Enterprise Edition that prunes only partial, internal participant ledger state freeing up space not needed for serving `ledger_api.transactions` and `ledger_api.completions` requests. In conjunction with `prune`, `prune_internally` enables pruning internal ledger state more aggressively than externally observable data via the ledger api. In most use cases `prune` should be used instead. Unlike `prune`, `prune_internally` has no visible effect on the Ledger API. The command returns `Unit` if the ledger has been successfully pruned or an error if the timestamp performs additional safety checks returning a `NOT_FOUND` error if `pruneUpTo` is higher than the offset returned by `find_safe_offset` on any domain with events preceding the pruning offset.

`pruning.set_cron`

Summary: Modify the cron used by automatic pruning.

Arguments:

- `cron`: String

Description: The schedule is specified in cron format and refers to pruning start times in the GMT time zone. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`pruning.set_max_duration`

Summary: Modify the maximum duration used by automatic pruning.

Arguments:

- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `maxDuration` is specified as a positive duration and has at most

per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`pruning.set_participant_schedule`

Summary: Activate automatic pruning according to the specified schedule with participant-specific options.

Arguments:

- `cron`: String
- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- `pruneInternallyOnly`: Boolean

Description: Refer to the `set_schedule` description for information about the `cron`, `max_duration`, and `retention` parameters. Setting the `prune_internally_only` flag causes pruning to only remove internal state as described in more detail in the `prune_internally` command description.

`pruning.set_retention`

Summary: Update the pruning retention used by automatic pruning.

Arguments:

- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `retention` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this update, pruning is actively running, a best effort is made to pause pruning and restart with the newly specified retention. This allows for the case that the new retention mandates retaining more data than previously.

`pruning.set_schedule`

Summary: Activate automatic pruning according to the specified schedule.

Arguments:

- `cron`: String
- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The schedule is specified in cron format and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period.

28.3.2.12 Bilateral Commitments

`commitments.computed`

Summary: Lookup ACS commitments locally computed as part of the reconciliation protocol

Arguments:

- `domain`: [com.digitalasset.canton.DomainAlias](#)
- `start`: `java.time.Instant`
- `end`: `java.time.Instant`
- `counterParticipant`: [Option\[com.digitalasset.canton.topology.ParticipantId\]](#)

Return type:

- Iterable[(com.digitalasset.canton.protocol.messages.CommitmentPeriod, com.digitalasset.canton.topology.ParticipantId, com.digitalasset.canton.protocol.messages.AcsCommitment.CommitmentType)]

commitments.help

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

commitments.received

Summary: Lookup ACS commitments received from other participants as part of the reconciliation protocol

Arguments:

- domain: [com.digitalasset.canton.DomainAlias](#)
- start: java.time.Instant
- end: java.time.Instant
- counterParticipant: [Option\[com.digitalasset.canton.topology.ParticipantId\]](#)

Return type:

- Iterable[com.digitalasset.canton.protocol.messages.SignedProtocolMessage[com.digitalasset.canton.protocol.messages.AcsCommitment]]

Description: The arguments are: - domain: the alias of the domain - start: lowest time exclusive - end: highest time inclusive - counterParticipant: optionally filter by counter participant

28.3.2.13 Participant Repair

repair.add

Summary: Add specified contracts to specific domain on local participant.

Arguments:

- domain: [com.digitalasset.canton.DomainAlias](#)
- contractsToAdd: Seq[com.digitalasset.canton.protocol.SerializableContractWithWitnesses]
- ignoreAlreadyAdded: Boolean
- ignoreStakeholderCheck: Boolean

Description: This is a last resort command to recover from data corruption, e.g. in scenarios in which participant contracts have somehow gotten out of sync and need to be manually created. The participant needs to be disconnected from the specified domain at the time of the call, and as of now the domain cannot have had any inflight requests. For each contractsToAdd, specify witnesses, local parties, in case no local party is a stakeholder. The ignoreAlreadyAdded flag makes it possible to invoke the command multiple times with the same parameters in case an earlier command invocation has failed. As repair commands are powerful tools to recover from unforeseen data corruption, but dangerous under normal operation, use of this command requires (temporarily) enabling the features.enable-repair-commands configuration. In addition repair commands can run for an unbounded time depending on the number of contracts passed in. Be sure to not connect the participant to the domain until the call returns. The arguments are: - domain: the alias of the domain to which to add the contract - contractsToAdd: list of contracts to add with witness information - ignoreAlreadyAdded: (default true) if set to true, it will ignore contracts that already exist on the target domain. - ignoreStakeholderCheck: (default false) if set to true, add will work for contracts that don't have a local

party (useful for party migration).

`repair.add`

Summary: Add specified contracts to specific domain on local participant.

Arguments:

- domainId: [com.digitalasset.canton.topology.DomainId](#)
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)
- contractsToAdd: [Seq\[com.digitalasset.canton.protocol.SerializableContractWithWitnesses\]](#)
- onboardedParties: [Set\[com.digitalasset.canton.topology.PartyId\]](#)

Description: This is a last resort command to recover from data corruption, e.g. in scenarios in which participant contracts have somehow gotten out of sync and need to be manually created. The participant needs to be disconnected from the specified domain at the time of the call, and as of now the domain cannot have had any inflight requests. The effects of the command will take affect upon reconnecting to the sync domain. As repair commands are powerful tools to recover from unforeseen data corruption, but dangerous under normal operation, use of this command requires (temporarily) enabling the `features.enable-repair-commands` configuration. In addition repair commands can run for an unbounded time depending on the number of contracts passed in. Be sure to not connect the participant to the domain until the call returns. The arguments are: - domainId: the id of the domain to which to add the contract - protocolVersion: to protocol version used by the domain - contractsToAdd: list of contracts to add with witness information

`repair.change_domain`

Summary: Move contracts with specified Contract IDs from one domain to another.

Arguments:

- contractIds: [Seq\[com.digitalasset.canton.protocol.LfContractId\]](#)
- sourceDomain: [com.digitalasset.canton.DomainAlias](#)
- targetDomain: [com.digitalasset.canton.DomainAlias](#)
- skipInactive: Boolean
- batchSize: Int

Description: This is a last resort command to recover from data corruption in scenarios in which a domain is irreparably broken and formerly connected participants need to move contracts to another, healthy domain. The participant needs to be disconnected from both the `sourceDomain` and the `targetDomain`. Also as of now the target domain cannot have had any inflight requests. Contracts already present in the target domain will be skipped, and this makes it possible to invoke this command in an idempotent fashion in case an earlier attempt had resulted in an error. The `skipInactive` flag makes it possible to only move active contracts in the `sourceDomain`. As repair commands are powerful tools to recover from unforeseen data corruption, but dangerous under normal operation, use of this command requires (temporarily) enabling the `features.enable-repair-commands` configuration. In addition repair commands can run for an unbounded time depending on the number of contract ids passed in. Be sure to not connect the participant to either domain until the call returns. Arguments: - contractIds - set of contract ids that should be moved to the new domain - sourceDomain - alias of the source domain - targetDomain - alias of the target domain - skipInactive - (default true) whether to skip inactive contracts mentioned in the contractIds list - batchSize - (default 100) how many contracts to write at once to the database

`repair.download`

Summary: Download all contracts for the given set of parties to a file.

Arguments:

- parties: [Set\[com.digitalasset.canton.topology.PartyId\]](#)

- partiesOffboarding: Boolean
- outputFile: String
- filterDomainId: String
- timestamp: Option[[java.time.Instant](#)]
- protocolVersion: [Option\[com.digitalasset.canton.version.ProtocolVersion\]](#)
- chunkSize: [Option\[com.digitalasset.canton.config.RequireTypes.PositiveInt\]](#)
- contractDomainRenames: Map[com.digitalasset.canton.topology.DomainId, com.digitalasset.canton.topology.DomainId]

Description: This command can be used to download the current active contract set of a given set of parties to a text file. This is mainly interesting for recovery and operational purposes. The file will contain base64 encoded strings, one line per contract. The lines are written sorted according to their domain and contract id. This allows to compare the contracts stored by two participants using standard file comparison tools. The domain-id is printed with the prefix domain-id before the block of contracts starts. This command may take a long time to complete and may require significant resources. It will first load the contract ids of the active contract set into memory and then subsequently load the contracts in batches and inspect their stakeholders. As this operation needs to traverse the entire datastore, it might take a long time to complete. The command will return a map of domainId -> number of active contracts stored. The arguments are: - parties: identifying contracts having at least one stakeholder from the given set - partiesOffboarding: true if the parties will be offboarded (party migration) - outputFile: the output file name where to store the data. Use .gz as a suffix to get a compressed file (recommended) - filterDomainId: restrict the export to a given domain - timestamp: optionally a timestamp for which we should take the state (useful to reconcile states of a domain) - protocolVersion: optional the protocol version to use for the serialization. Defaults to the one of the domains. - chunkSize: size of the byte chunks to stream back: default 1024 * 1024 * 2 = (2MB) - contractDomainRenames: As part of the export, allow to rename the associated domain id of contracts from one domain to another based on the mapping.

[repair.export_acs](#)

Summary: Export active contracts for the given set of parties to a file.

Arguments:

- parties: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- partiesOffboarding: Boolean
- outputFile: String
- filterDomainId: [Option\[com.digitalasset.canton.topology.DomainId\]](#)
- timestamp: Option[[java.time.Instant](#)]
- contractDomainRenames: Map[com.digitalasset.canton.topology.DomainId, com.digitalasset.canton.topology.DomainId, com.digitalasset.canton.version.ProtocolVersion]

Description: This command exports the current Active Contract Set (ACS) of a given set of parties to ACS snapshot file. Afterwards, the 'import_acs' command allows importing it into a participant's ACS again. Such ACS export (and import) is interesting for recovery and operational purposes only. Note that the 'export_acs' command execution may take a long time to complete and may require significant resources. The arguments are: - parties: identifying contracts having at least one stakeholder from the given set - partiesOffboarding: true if the parties will be offboarded (party migration) - outputFile: the output file name where to store the data. Use .gz as a suffix to get a compressed file (recommended) - filterDomainId: restrict the export to a given domain - timestamp: optionally a timestamp for which we should take the state (useful to reconcile states of a domain) - contractDomainRenames: As part of the export, allow to rename the associated domain id of contracts from one domain to another based on the mapping.

repair.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

repair.ignore_events

Summary: Mark sequenced events as ignored.

Arguments:

- `domainId`: [com.digitalasset.canton.topology.DomainId](#)
- `fromInclusive`: [com.digitalasset.canton.SequencerCounter](#)
- `toInclusive`: [com.digitalasset.canton.SequencerCounter](#)
- `force`: Boolean

Description: This is the last resort to ignore events that the participant is unable to process. Ignoring events may lead to subsequent failures, e.g., if the event creating a contract is ignored and that contract is subsequently used. It may also lead to ledger forks if other participants still process the ignored events. It is possible to mark events as ignored that the participant has not yet received. The command will fail, if marking events between `fromInclusive` and `toInclusive` as ignored would result in a gap in sequencer counters, namely if `from` \leq `to` and `from` is greater than `maxSequencerCounter + 1`, where `maxSequencerCounter` is the greatest sequencer counter of a sequenced event stored by the underlying participant. The command will also fail, if `force == false` and `from` is smaller than the sequencer counter of the last event that has been marked as clean. (Ignoring such events would normally have no effect, as they have already been processed.)

repair.import_acs

Summary: Import active contracts from an Active Contract Set (ACS) snapshot file.

Arguments:

- `inputFile`: String
- `onboardedParties`: [Set\[com.digitalasset.canton.topology.PartyId\]](#)
- `workflowIdPrefix`: String

Description: This command imports contracts from an ACS snapshot file into the participant's ACS. The given ACS snapshot file needs to be the resulting file from a previous 'export_acs' command invocation. Arguments are: - `inputFile`: the path to the file containing the ACS export - `onboardedParties`: the list of new parties whose contracts are imported

repair.migrate_domain

Summary: Migrate contracts from one domain to another one.

Arguments:

- `source`: [com.digitalasset.canton.DomainAlias](#)
- `target`: [com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)
- `force`: Boolean

Description: Migrates all contracts associated with a domain to a new domain. This method will register the new domain, connect to it and then re-associate all contracts from the source domain to the target domain. Please note that this migration needs to be done by all participants at the same time. The target domain should only be used once all participants have finished their migration. **WARNING:** The migration does not start in case of in-flight transactions on the source domain. Forcing the migration may lead to a ledger fork! Instead of forcing the migration, ensure the source domain has no in-flight transactions by reconnecting all participants to the source domain, halting activity on these participants and waiting for the in-flight transactions to complete or time out. Forcing a migration is intended for disaster recovery when a source domain cannot be recovered

anymore. The arguments are: `source`: the domain alias of the source domain `target`: the configuration for the target domain `force`: if true, migration is forced ignoring in-flight transactions. Defaults to false.

`repair.purge`

Summary: Purge contracts with specified Contract IDs from local participant.

Arguments:

- `domain`: `com.digitalasset.canton.DomainAlias`
- `contractIds`: `Seq[com.digitalasset.canton.protocol.LfContractId]`
- `offboardedParties`: `Set[com.digitalasset.canton.topology.PartyId]`
- `ignoreAlreadyPurged`: `Boolean`

Description: This is a last resort command to recover from data corruption, e.g. in scenarios in which participant contracts have somehow gotten out of sync and need to be manually purged, or in situations in which stakeholders are no longer available to agree to their archival. The participant needs to be disconnected from the domain on which the contracts with `contractIds` reside at the time of the call, and as of now the domain cannot have had any inflight requests. The effects of the command will take effect upon reconnecting to the sync domain. The `ignoreAlreadyPurged` flag makes it possible to invoke the command multiple times with the same parameters in case an earlier command invocation has failed. As repair commands are powerful tools to recover from unforeseen data corruption, but dangerous under normal operation, use of this command requires (temporarily) enabling the `features.enable-repair-commands` configuration. In addition repair commands can run for an unbounded time depending on the number of contract ids passed in. Be sure to not connect the participant to the domain until the call returns. Arguments are: - `inputFile`: the path to the file containing the ACS export - `offboardedParties`: the list of parties that will be offboarded after the purge.

`repair.purge_deactivated_domain`

Summary: Purge select data of a deactivated domain.

Arguments:

- `domain`: `com.digitalasset.canton.DomainAlias`

Description: This command deletes selected domain data and helps to ensure that stale data in the specified, deactivated domain is not acted upon anymore. The specified domain needs to be in the *Inactive* status for purging to occur. Purging a deactivated domain is typically performed automatically as part of a hard domain migration via `repair.migrate_domain`.

`repair.unignore_events`

Summary: Remove the ignored status from sequenced events.

Arguments:

- `domainId`: `com.digitalasset.canton.topology.DomainId`
- `fromInclusive`: `com.digitalasset.canton.SequencerCounter`
- `toInclusive`: `com.digitalasset.canton.SequencerCounter`
- `force`: `Boolean`

Description: This command has no effect on ordinary (i.e., not ignored) events and on events that do not exist. The command will fail, if marking events between *fromInclusive* and *toInclusive* as unignored would result in a gap in sequencer counters, namely if there is one empty ignored event with sequencer counter between *from* and *to* and another empty ignored event with sequencer counter greater than *to*. An empty ignored event is an event that has been marked as ignored and not yet received by the participant. The command will also fail, if `force == false` and *from* is smaller than the sequencer counter of the last event that has been marked as clean. (Unignoring such events would normally have no effect, as they have already been processed.)

`repair.upload`

Summary: Import ACS snapshot

Arguments:

- `inputFile`: String

Description: Uploads a binary into the participant's ACS

28.3.2.14 Resource Management

`resources.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`resources.resource_limits`

Summary: Get the resource limits of the participant.

Return type:

- `com.digitalasset.canton.participant.admin.ResourceLimits`

`resources.set_resource_limits`

Summary: Set resource limits for the participant.

Arguments:

- `limits`: `com.digitalasset.canton.participant.admin.ResourceLimits`

Description: While a resource limit is attained or exceeded, the participant will reject any additional submission with GRPC status ABORTED. Most importantly, a submission will be rejected **before** it consumes a significant amount of resources. There are three kinds of limits: `maxDirtyRequests`, `maxRate` and `maxBurstFactor`. The number of dirty requests of a participant P covers (1) requests initiated by P as well as (2) requests initiated by participants other than P that need to be validated by P. Compared to the maximum rate, the maximum number of dirty requests reflects the load on the participant more accurately. However, the maximum number of dirty requests alone does not protect the system from bursts : If an application submits a huge number of commands at once, the maximum number of dirty requests will likely be exceeded, as the system is registering dirty requests only during validation and not already during submission. The maximum rate is a hard limit on the rate of commands submitted to this participant through the ledger API. As the rate of commands is checked and updated immediately after receiving a new command submission, an application cannot exceed the maximum rate. The `maxBurstFactor` parameter (positive, default 0.5) allows to configure how permissive the rate limitation should be with respect to bursts. The rate limiting will be enforced strictly after having observed `max_burst * max_rate` commands. For the sake of illustration, let's assume the configured rate limit is 100 commands/s with a burst ratio of 0.5. If an application submits 100 commands within a single second, waiting exactly 10 milliseconds between consecutive commands, then the participant will accept all commands. With a `maxBurstFactor` of 0.5, the participant will accept the first 50 commands and reject the remaining 50. If the application then waits another 500 ms, it may submit another burst of 50 commands. If it waits 250 ms, it may submit only a burst of 25 commands. Resource limits can only be changed, if the server runs Canton enterprise. In the community edition, the server uses fixed limits that cannot be changed.

28.3.2.15 Replication

`replication.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`replication.set_passive`

Summary: Set the participant replica to passive

Return type:

- `Boolean`

Description: Trigger a graceful fail-over from this active replica to another passive replica. Returns true if another replica became active.

28.3.3 Multiple Participants

This section lists the commands available for a sequence of participants. They can be used on the participant references `participants.all`, `.local` or `.remote` as:

```
participants.all.dars.upload("my.dar")
```

`dars.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`dars.upload`

Summary: Upload DARs to participants

Arguments:

- `darPath: String`
- `vetAllPackages: Boolean`
- `synchronizeVetting: Boolean`

Return type:

- `Map[com.digitalasset.canton.console.ParticipantReference,String]`

Description: If `vetAllPackages` is true, the participants will vet the package on all domains they are registered. If `synchronizeVetting` is true, the command will block until the package vetting transaction has been registered with all connected domains.

`dars.validate`

Summary: Validate DARs against the current participants' state

Arguments:

- `darPath: String`

Return type:

- `Map[com.digitalasset.canton.console.ParticipantReference,String]`

Description: Performs the same DAR and Daml package validation checks that the upload call performs, but with no effects on the target participants: the DAR is not persisted or vetted.

`domains.connect_local`

Summary: Register and potentially connect to new local domain

Arguments:

- domain: [com.digitalasset.canton.console.InstanceReferenceWithSequencerConnection](#)
- manualConnect: Boolean
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)

Description: The arguments are: domain - A local domain or sequencer reference manualConnect - Whether this connection should be handled manually and also excluded from automatic re-connect. synchronize - A timeout duration indicating how long to wait for all topology changes to have been effected on all local nodes.

[domains.disconnect](#)

Summary: Disconnect from domain

Arguments:

- alias: [com.digitalasset.canton.DomainAlias](#)

[domains.disconnect_all](#)

Summary: Disconnect from all connected domains

[domains.disconnect_local](#)

Summary: Disconnect from a local domain

Arguments:

- domain: [com.digitalasset.canton.console.LocalDomainReference](#)

[domains.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[domains.reconnect](#)

Summary: Reconnect to domain

Arguments:

- alias: [com.digitalasset.canton.DomainAlias](#)
- retry: Boolean

Description: If retry is set to true (default), the command will return after the first attempt, but keep on trying in the background.

[domains.reconnect_all](#)

Summary: Reconnect to all domains for which *manualStart* = false

Arguments:

- ignoreFailures: Boolean

Description: If ignoreFailures is set to true (default), the reconnect all will succeed even if some domains are offline. The participants will continue attempting to establish a domain connection.

[domains.register](#)

Summary: Register and potentially connect to domain

Arguments:

- config: [com.digitalasset.canton.participant.domain.DomainConnectionConfig](#)

28.3.4 Domain Administration Commands

`clear_cache` (Testing)

Summary: Clear locally cached variables

Description: Some commands cache values on the client side. Use this command to explicitly clear the caches of these values.

`config`

Summary: Returns the domain configuration

Return type:

- `LocalDomainReference.this.consoleEnvironment.environment.config.DomainConfigType`

`defaultDomainConnection`

Summary: Yields a domain connection config with default values except for the domain alias and the sequencer connection. May throw an exception if the domain alias or sequencer connection is misconfigured.

Return type:

- `com.digitalasset.canton.participant.domain.DomainConnectionConfig`

`help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`id`

Summary: Yields the globally unique id of this domain. Throws an exception, if the id has not yet been allocated (e.g., the domain has not yet been started).

Return type:

- `com.digitalasset.canton.topology.DomainId`

`is_initialized`

Summary: Check if the local instance is running and is fully initialized

Return type:

- Boolean

`is_running`

Summary: Check if the local instance is running

Return type:

- Boolean

`start`

Summary: Start the instance

`stop`

Summary: Stop the instance

28.3.4.1 Health

`health.active`

Summary: Check if the node is running and is the active instance (mediator, participant)

Return type:

- Boolean

`health.dump`

Summary: Creates a zip file containing diagnostic information about the canton process running this node

Arguments:

- `outputFile`: `better.files.File`
- `timeout`: `com.digitalasset.canton.config.NonNegativeDuration`
- `chunkSize`: `Option[Int]`

Return type:

- String

`health.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`health.initialized`

Summary: Returns true if node has been initialized.

Return type:

- Boolean

`health.last_error_trace`

Summary: Show all messages logged with the given `traceId` in a recent interval

Arguments:

- `traceId`: String

Return type:

- `Seq[String]`

Description: Returns a list of buffered log messages associated to a given trace-id. Usually, the trace-id is taken from `last_errors()`

`health.last_errors`

Summary: Show the last errors logged

Return type:

- `Map[String,String]`

Description: Returns a map with the trace-id as key and the most recent error messages as value. Requires that `-log-last-errors` is enabled (and not turned off).

`health.running`

Summary: Check if the node is running

Return type:

- Boolean

`health.set_log_level`

Summary: Change the log level of the process

Arguments:

- `level`: `ch.qos.logback.classic.Level`

Description: If the default logback configuration is used, this will change the log level of the process.

`health.status`

Summary: Get human (and machine) readable participant status information

Return type:

- `com.digitalasset.canton.admin.api.client.data.NodeStatus[S]`

`health.wait_for_identity`

Summary: Wait for the node to have an identity

Description: This is specifically useful for the Domain Manager which needs its identity to be ready for bootstrapping, but for which we can't rely on `wait_for_initialized()` because it will be initialized only after being bootstrapped.

`health.wait_for_initialized`

Summary: Wait for the node to be initialized

`health.wait_for_running`

Summary: Wait for the node to be running

28.3.4.2 Database

`db.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`db.migrate`

Summary: Migrates the instance's database if using a database storage

Description: When instances reside on different nodes, their database migration can be run in parallel to save time. Please note that the migration commands must however be run on each node individually, because remote migration through `participants.remote` is not supported.

`db.repair_migration`

Summary: Only use when advised - repairs the database migration of the instance's database

Arguments:

- `force: Boolean`

Description: In some rare cases, we change already applied database migration files in a new release and the repair command resets the checksums we use to ensure that in general already applied migration files have not been changed. You should only use `db.repair_migration` when advised and otherwise use it at your own risk - in the worst case running it may lead to data corruption when an incompatible database migration (one that should be rejected because the already applied database migration files have changed) is subsequently falsely applied.

28.3.4.3 Participants

`participants.active`

Summary: Test whether a participant is permissioned on this domain

Arguments:

- participantId: `com.digitalasset.canton.topology.ParticipantId`

Return type:

- Boolean

`participants.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

`participants.list`

Summary: List participant states

Return type:

- `Seq[com.digitalasset.canton.admin.api.client.data.ListParticipantDomain-StateResult]`

Description: This command will list the currently valid state as stored in the authorized store. For a deep inspection of the identity management history, use the `topology.participant_domain_states.list` command.

`participants.set_state`

Summary: Change state and trust level of participant

Arguments:

- participant: `com.digitalasset.canton.topology.ParticipantId`
- permission: `com.digitalasset.canton.topology.transaction.ParticipantPermission`
- trustLevel: `com.digitalasset.canton.topology.transaction.TrustLevel`
- synchronize: `Option[com.digitalasset.canton.config.NonNegativeDuration]`

Description: Set the state of the participant within the domain. Valid permissions are 'Submission', 'Confirmation', 'Observation' and 'Disabled'. Valid trust levels are 'Vip' and 'Ordinary'. Synchronize timeout can be used to ensure that the state has been propagated into the node

28.3.4.4 Sequencer

`sequencer.disable_member`

Summary: Disable the provided member at the Sequencer that will allow any unread data for them to be removed

Arguments:

- member: `com.digitalasset.canton.topology.Member`

Description: This will prevent any client for the given member to reconnect the Sequencer and allow any unread/unacknowledged data they have to be removed. This should only be used if the domain operation is confident the member will never need to reconnect as there is no way to re-enable the member. To view members using the sequencer run `sequencer.status()`.

`sequencer.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

sequencer.pruning.clear_schedule

Summary: Deactivate automatic pruning.

sequencer.pruning.force_prune

Summary: Force remove data from the Sequencer including data that may have not been read by offline clients

Arguments:

- dryRun: Boolean

Return type:

- String

Description: Will force pruning up until the default retention period by potentially disabling clients that have not yet read data we would like to remove. Disabling these clients will prevent them from ever reconnecting to the Domain so should only be used if the Domain operator is confident they can be permanently ignored. Run with *dryRun = true* to review a description of which clients will be disabled first. Run with *dryRun = false* to disable these clients and perform a forced pruning.

sequencer.pruning.force_prune_at

Summary: Force removing data from the Sequencer including data that may have not been read by offline clients up until the specified time

Arguments:

- timestamp: [com.digitalasset.canton.data.CantonTimestamp](#)
- dryRun: Boolean

Return type:

- String

Description: Similar to the above *force_prune* command but allows specifying the exact time at which to prune

sequencer.pruning.force_prune_with_retention_period

Summary: Force removing data from the Sequencer including data that may have not been read by offline clients up until a custom retention period

Arguments:

- retentionPeriod: `scala.concurrent.duration.FiniteDuration`
- dryRun: Boolean

Return type:

- String

Description: Similar to the above *force_prune* command but allows specifying a custom retention period

sequencer.pruning.get_schedule

Summary: Inspect the automatic pruning schedule.

Return type:

- [Option\[com.digitalasset.canton.admin.api.client.data.PruningSchedule\]](#)

Description: The schedule consists of a `cron` expression and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period. Returns *None* if no schedule has been configured via *set_schedule* or if *clear_schedule* has been invoked.

sequencer.pruning.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`sequencer.pruning.locate_pruning_timestamp`

Summary: Obtain a timestamp at or near the beginning of sequencer state

Arguments:

- `index`: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Option\[com.digitalasset.canton.data.CantonTimestamp\]](#)

Description: This command provides insight into the current state of sequencer pruning when called with the default value of `index 1`. When pruning the sequencer manually via `prune_at` and with the intent to prune in batches, specify a value such as 1000 to obtain a pruning timestamp that corresponds to the `end` of the batch.

`sequencer.pruning.prune`

Summary: Remove unnecessary data from the Sequencer up until the default retention point

Return type:

- String

Description: Removes unnecessary data from the Sequencer that is earlier than the default retention period. The default retention period is set in the configuration of the canton processing running this command under `parameters.retention-period-defaults.sequencer`. This pruning command requires that data is read and acknowledged by clients before considering it safe to remove. If no data is being removed it could indicate that clients are not reading or acknowledging data in a timely fashion (typically due to nodes going offline for long periods). You have the option of disabling the members running on these nodes to allow removal of this data, however this will mean that they will be unable to reconnect to the domain in the future. To do this run `force_prune(dryRun = true)` to return a description of which members would be disabled in order to prune the Sequencer. If you are happy to disable the described clients then run `force_prune(dryRun = false)` to permanently remove their unread data. Once offline clients have been disabled you can continue to run `prune` normally.

`sequencer.pruning.prune_at`

Summary: Remove data that has been read up until the specified time

Arguments:

- `timestamp`: [com.digitalasset.canton.data.CantonTimestamp](#)

Return type:

- String

Description: Similar to the above `prune` command but allows specifying the exact time at which to prune. The command will fail if a client has not yet read and acknowledged some data up to the specified time.

`sequencer.pruning.prune_with_retention_period`

Summary: Remove data that has been read up until a custom retention period

Arguments:

- `retentionPeriod`: `scala.concurrent.duration.FiniteDuration`

Return type:

- String

Description: Similar to the above `prune` command but allows specifying a custom retention period

`sequencer.pruning.set_cron`

Summary: Modify the cron used by automatic pruning.

Arguments:

- `cron`: String

Description: The schedule is specified in cron format and refers to pruning start times in the GMT time zone. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`sequencer.pruning.set_max_duration`

Summary: Modify the maximum duration used by automatic pruning.

Arguments:

- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `maxDuration` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`sequencer.pruning.set_retention`

Summary: Update the pruning retention used by automatic pruning.

Arguments:

- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `retention` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this update, pruning is actively running, a best effort is made to pause pruning and restart with the newly specified retention. This allows for the case that the new retention mandates retaining more data than previously.

`sequencer.pruning.set_schedule`

Summary: Activate automatic pruning according to the specified schedule.

Arguments:

- `cron`: String
- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The schedule is specified in cron format and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period.

`sequencer.pruning.status`

Summary: Status of the sequencer and its connected clients

Return type:

- [com.digitalasset.canton.domain.sequencing.sequencer.SequencerPruningStatus](#)

Description: Provides a detailed breakdown of information required for pruning: - the current time according to this sequencer instance - domain members that the sequencer supports - for each member when they were registered and whether they are enabled - a list of clients for each member, their last acknowledgement, and whether they are enabled

28.3.4.5 Mediator

`mediator.clear_schedule`

Summary: Deactivate automatic pruning.

`mediator.get_schedule`

Summary: Inspect the automatic pruning schedule.

Return type:

- [Option\[com.digitalasset.canton.admin.api.client.data.PruningSchedule\]](#)

Description: The schedule consists of a `cron` expression and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period. Returns `None` if no schedule has been configured via `set_schedule` or if `clear_schedule` has been invoked.

`mediator.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`mediator.locate_pruning_timestamp`

Summary: Obtain a timestamp at or near the beginning of mediator state

Arguments:

- `index`: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Option\[com.digitalasset.canton.data.CantonTimestamp\]](#)

Description: This command provides insight into the current state of mediator pruning when called with the default value of `index 1`. When pruning the mediator manually via `prune_at` and with the intent to prune in batches, specify a value such as 1000 to obtain a pruning timestamp that corresponds to the `end` of the batch.

`mediator.prune`

Summary: Prune the mediator of unnecessary data while keeping data for the default retention period

Description: Removes unnecessary data from the Mediator that is earlier than the default retention period. The default retention period is set in the configuration of the canton node running this command under `parameters.retention-period-defaults.mediator`.

`mediator.prune_at`

Summary: Prune the mediator of unnecessary data up to and including the given timestamp

Arguments:

- `timestamp`: [com.digitalasset.canton.data.CantonTimestamp](#)

`mediator.prune_with_retention_period`

Summary: Prune the mediator of unnecessary data while keeping data for the provided retention period

Arguments:

- `retentionPeriod`: `scala.concurrent.duration.FiniteDuration`

`mediator.set_cron`

Summary: Modify the cron used by automatic pruning.

Arguments:

- `cron`: String

Description: The schedule is specified in cron format and refers to pruning start times in the GMT time zone. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`mediator.set_max_duration`

Summary: Modify the maximum duration used by automatic pruning.

Arguments:

- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `maxDuration` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`mediator.set_retention`

Summary: Update the pruning retention used by automatic pruning.

Arguments:

- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `retention` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this update, pruning is actively running, a best effort is made to pause pruning and restart with the newly specified retention. This allows for the case that the new retention mandates retaining more data than previously.

`mediator.set_schedule`

Summary: Activate automatic pruning according to the specified schedule.

Arguments:

- `cron`: String
- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The schedule is specified in cron format and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period.

`mediator.testing.await_domain_time (Testing)`

Summary: Await for the given time to be reached on the domain

Arguments:

- `time`: [com.digitalasset.canton.data.CantonTimestamp](#)
- `timeout`: [com.digitalasset.canton.config.NonNegativeDuration](#)

`mediator.testing.fetch_domain_time (Testing)`

Summary: Fetch the current time from the domain

Arguments:

- `timeout`: [com.digitalasset.canton.config.NonNegativeDuration](#)

Return type:

- [com.digitalasset.canton.data.CantonTimestamp](#)

[mediator.testing.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

28.3.4.6 Key Administration

[keys.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

[keys.public.download](#)

Summary: Download public key

Arguments:

- `fingerprint: com.digitalasset.canton.crypto.Fingerprint`
- `protocolVersion: com.digitalasset.canton.version.ProtocolVersion`

Return type:

- `com.google.protobuf.ByteString`

[keys.public.download_to](#)

Summary: Download public key and save it to a file

Arguments:

- `fingerprint: com.digitalasset.canton.crypto.Fingerprint`
- `outputFile: String`
- `protocolVersion: com.digitalasset.canton.version.ProtocolVersion`

[keys.public.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

[keys.public.list](#)

Summary: List public keys in registry

Arguments:

- `filterFingerprint: String`
- `filterContext: String`

Return type:

- `Seq[com.digitalasset.canton.crypto.PublicKeyWithName]`

Description: Returns all public keys that have been added to the key registry. Optional arguments can be used for filtering.

[keys.public.list_by_owner](#)

Summary: List keys for given keyOwner.

Arguments:

- `keyOwner: com.digitalasset.canton.topology.KeyOwner`
- `filterDomain: String`
- `asOf: Option[java.time.Instant]`
- `limit: com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListKeyOwnersResult\]](#)

Description: This command is a convenience wrapper for `list_key_owners`, taking an explicit `keyOwner` as search argument. The response includes the public keys.

[keys.public.list_owners](#)

Summary: List active owners with keys for given search arguments.

Arguments:

- `filterKeyOwnerId`: String
- `filterKeyOwnerType`: [Option\[com.digitalasset.canton.topology.KeyOwner-Code\]](#)
- `filterDomain`: String
- `asOf`: [Option\[java.time.Instant\]](#)
- `limit`: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListKeyOwnersResult\]](#)

Description: This command allows deep inspection of the topology state. The response includes the public keys. Optional `filterKeyOwnerType` type can be 'ParticipantId.Code', 'MediatorId.Code', 'SequencerId.Code', 'DomainTopologyManagerId.Code'.

[keys.public.upload](#)

Summary: Upload public key

Arguments:

- `filename`: String
- `name`: [Option\[String\]](#)

Return type:

- [com.digitalasset.canton.crypto.Fingerprint](#)

[keys.secret.upload](#)

Summary: Upload public key

Arguments:

- `keyBytes`: [com.google.protobuf.ByteString](#)
- `name`: [Option\[String\]](#)

Return type:

- [com.digitalasset.canton.crypto.Fingerprint](#)

Description: Import a public key and store it together with a name used to provide some context to that key.

[keys.secret.delete](#)

Summary: Delete private key

Arguments:

- `fingerprint`: [com.digitalasset.canton.crypto.Fingerprint](#)
- `force`: Boolean

[keys.secret.download](#)

Summary: Download key pair

Arguments:

- `fingerprint`: [com.digitalasset.canton.crypto.Fingerprint](#)
- `protocolVersion`: [com.digitalasset.canton.version.ProtocolVersion](#)

Return type:

- [com.google.protobuf.ByteString](#)

[keys.secret.download_to](#)

Summary: Download key pair and save it to a file

Arguments:

- fingerprint: [com.digitalasset.canton.crypto.Fingerprint](#)
- outputFile: `String`
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)

[keys.secret.generate_encryption_key](#)

Summary: Generate new public/private key pair for encryption and store it in the vault

Arguments:

- name: `String`
- scheme: [Option\[com.digitalasset.canton.crypto.EncryptionKeyScheme\]](#)

Return type:

- [com.digitalasset.canton.crypto.EncryptionPublicKey](#)

Description: The optional name argument allows you to store an associated string for your convenience. The scheme can be used to select a key scheme and the default scheme is used if left unspecified.

[keys.secret.generate_signing_key](#)

Summary: Generate new public/private key pair for signing and store it in the vault

Arguments:

- name: `String`
- scheme: [Option\[com.digitalasset.canton.crypto.SigningKeyScheme\]](#)

Return type:

- [com.digitalasset.canton.crypto.SigningPublicKey](#)

Description: The optional name argument allows you to store an associated string for your convenience. The scheme can be used to select a key scheme and the default scheme is used if left unspecified.

[keys.secret.get_wrapper_key_id](#)

Summary: Get the wrapper key id that is used for the encrypted private keys store

Return type:

- `String`

[keys.secret.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

[keys.secret.list](#)

Summary: List keys in private vault

Arguments:

- filterFingerprint: `String`
- filterName: `String`
- purpose: [Set\[com.digitalasset.canton.crypto.KeyPurpose\]](#)

Return type:

- [Seq\[com.digitalasset.canton.crypto.admin.grpc.PrivateKeyMetadata\]](#)

Description: Returns all public keys to the corresponding private keys in the key vault. Optional arguments can be used for filtering.

[keys.secret.register_kms_encryption_key](#)

Summary: Register the specified KMS encryption key in canton storing its public information in the vault

Arguments:

- kmsKeyId: `String`
- name: `String`

Return type:

- [com.digitalasset.canton.crypto.EncryptionPublicKey](#)

Description: The id for the KMS encryption key. The optional name argument allows you to store an associated string for your convenience.

[keys.secret.register_kms_signing_key](#)

Summary: Register the specified KMS signing key in canton storing its public information in the vault

Arguments:

- kmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.SigningPublicKey](#)

Description: The id for the KMS signing key. The optional name argument allows you to store an associated string for your convenience.

[keys.secret.rotate_kms_node_key](#)

Summary: Rotate a given node's keypair with a new pre-generated KMS keypair

Arguments:

- fingerprint: String
- newKmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates an existing encryption or signing key stored externally in a KMS with a pre-generated key. For a sequencer or mediator node use `rotate_kms_node_key` with a domain manager reference as an argument. The fingerprint of the key we want to rotate. The id of the new KMS key (e.g. Resource Name). An optional name for the new key.

[keys.secret.rotate_node_key](#)

Summary: Rotate a node's public/private key pair

Arguments:

- fingerprint: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates an existing encryption or signing key. NOTE: A namespace root or intermediate signing key CANNOT be rotated by this command. For a sequencer or mediator node use `rotate_kms_node_key` with a domain manager reference as an argument. The fingerprint of the key we want to rotate. An optional name for the new key.

[keys.secret.rotate_node_keys](#)

Summary: Rotate the node's public/private key pairs

Description: For a participant node it rotates the signing and encryption key pair. For a domain or domain manager node it rotates the signing key pair as those nodes do not have an encryption key pair. For a sequencer or mediator node use `rotate_node_keys` with a domain manager reference as an argument. NOTE: Namespace root or intermediate signing keys are NOT rotated by this command.

[keys.secret.rotate_wrapper_key](#)

Summary: Change the wrapper key for encrypted private keys store

Arguments:

- newWrapperKeyId: String

Description: Change the wrapper key (e.g. AWS KMS key) being used to encrypt the private

keys in the store. `newWrapperKeyId`: The optional new wrapper key id to be used. If the wrapper key id is empty Canton will generate a new key based on the current configuration.

`keys.secret.upload`

Summary: Upload a key pair

Arguments:

- `pairBytes`: `com.google.protobuf.ByteString`
- `name`: `Option[String]`

`keys.secret.upload`

Summary: Upload (load and import) a key pair from file

Arguments:

- `filename`: `String`
- `name`: `Option[String]`

28.3.4.7 Parties

`parties.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: `String`

`parties.list`

Summary: List active parties, their active participants, and the participants' permissions on domains.

Arguments:

- `filterParty`: `String`
- `filterParticipant`: `String`
- `filterDomain`: `String`
- `asOf`: `Option[java.time.Instant]`
- `limit`: `com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- `Seq[com.digitalasset.canton.admin.api.client.data.ListPartiesResult]`

Description: Inspect the parties known by this participant as used for synchronisation. The response is built from the timestamped topology transactions of each domain, excluding the authorized store of the given node. For each known party, the list of active participants and their permission on the domain for that party is given. `filterParty`: Filter by parties starting with the given string. `filterParticipant`: Filter for parties that are hosted by a participant with an id starting with the given string `filterDomain`: Filter by domains whose id starts with the given string. `asOf`: Optional timestamp to inspect the topology state at a given point in time. `limit`: Limit on the number of parties fetched (defaults to `canton.parameters.console.default-limit`). Example: `participant1.parties.list(filterParty= alice)`

28.3.4.8 Service

`service.get_dynamic_domain_parameters`

Summary: Get the Dynamic Domain Parameters configured for the domain

Return type:

- [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#)

`service.get_max_rate_per_participant`

Summary: Get the max rate per participant

Return type:

- [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

Description: Depending on the protocol version used on the domain, the value will be read either from the static domain parameters or the dynamic ones.

`service.get_max_request_size`

Summary: Get the max request size

Return type:

- [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

Description: Depending on the protocol version used on the domain, the value will be read either from the static domain parameters or the dynamic ones. This value is not necessarily the one used by the sequencer node because it requires a restart of the server to be taken into account.

`service.get_mediator_deduplication_timeout`

Summary: Get the mediator deduplication timeout

Return type:

- [com.digitalasset.canton.config.NonNegativeFiniteDuration](#)

Description: The method will fail, if the domain does not support the mediatorDeduplicationTimeout.

`service.get_reconciliation_interval`

Summary: Get the reconciliation interval configured for the domain

Return type:

- [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: Depending on the protocol version used on the domain, the value will be read either from the static domain parameters or the dynamic ones.

`service.get_static_domain_parameters`

Summary: Get the Static Domain Parameters configured for the domain

Return type:

- [com.digitalasset.canton.admin.api.client.data.StaticDomainParameters](#)

`service.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`service.list_accepted_agreements`

Summary: List the accepted service agreements

Return type:

- [Seq\[com.digitalasset.canton.domain.service.ServiceAgreementAcceptance\]](#)

`service.set_commitments_catch_up_config`

Summary: Update the ACS commitments catch up config for the domain

Arguments:

- config: [com.digitalasset.canton.protocol.CatchUpConfig](#)

Description: The method will fail if the domain does not support the `catchUpConfig` parameter (i.e., if the domain is running on protocol version lower than 6)

[**service.set_dynamic_domain_parameters**](#)

Summary: Set the Dynamic Domain Parameters configured for the domain

Arguments:

- dynamicDomainParameters: [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#)
- force: Boolean

Description: force: Enable potentially dangerous changes. Required to increase `ledgerTimeRecordTimeTolerance`. Use `set_ledger_time_record_time_tolerance` to securely increase `ledgerTimeRecordTimeTolerance`.

[**service.set_ledger_time_record_time_tolerance**](#)

Summary: Update the `ledgerTimeRecordTimeTolerance` in the dynamic domain parameters.

Arguments:

- newLedgerTimeRecordTimeTolerance: [com.digitalasset.canton.config.NonNegativeFiniteDuration](#)
- force: Boolean

Description: If it would be insecure to perform the change immediately, the command will block and wait until it is secure to perform the change. The command will block for at most twice of `newLedgerTimeRecordTimeTolerance`. If the domain does not support `mediatorDeduplicationTimeout`, the method will update `ledgerTimeRecordTimeTolerance` immediately without blocking. The method will fail if `mediatorDeduplicationTimeout` is less than twice of `newLedgerTimeRecordTimeTolerance`. Do not modify domain parameters concurrently while running this command, because the command may override concurrent changes. force: update `ledgerTimeRecordTimeTolerance` immediately without blocking. This is safe to do during domain bootstrapping and in test environments, but should not be done in operational production systems..

[**service.set_max_inbound_message_size**](#)

Summary: Try to update the max rate per participant for the domain

Arguments:

- maxRequestSize: [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)
- force: Boolean

Description: If the max request size is dynamic, update the value. The update won't have any effect unless the sequencer server is restarted. If the max request size is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

[**service.set_max_rate_per_participant**](#)

Summary: Try to update the max rate per participant for the domain

Arguments:

- maxRatePerParticipant: [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

Description: If the max rate per participant is dynamic, update the value. If the max rate per participant is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

[**service.set_max_request_size**](#)

Summary: Try to update the max rate per participant for the domain

Arguments:

- maxRequestSize: [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

- force: Boolean

Description: If the max request size is dynamic, update the value. The update won't have any effect unless the sequencer server is restarted. If the max request size is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

`service.set_mediator_deduplication_timeout`

Summary: Update the mediator deduplication timeout

Arguments:

- newMediatorDeduplicationTimeout: `com.digitalasset.canton.config.NonNegativeFiniteDuration`

Description: The method will fail: - if the domain does not support the `mediatorDeduplicationTimeout` parameter, - if the new value of `mediatorDeduplicationTimeout` is less than twice the value of `ledgerTimeRecordTimeTolerance`.

`service.set_reconciliation_interval`

Summary: Try to update the reconciliation interval for the domain

Arguments:

- newReconciliationInterval: `com.digitalasset.canton.config.PositiveDurationSeconds`

Description: If the reconciliation interval is dynamic, update the value. If the reconciliation interval is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

`service.update_dynamic_domain_parameters`

Summary: Update the Dynamic Domain Parameters for the domain

Arguments:

- modifier: `com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters => com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters`
- force: Boolean

Description: force: Enable potentially dangerous changes. Required to increase `ledgerTimeRecordTimeTolerance`. Use `set_ledger_time_record_time_tolerance_securely` to securely increase `ledgerTimeRecordTimeTolerance`.

`service.update_dynamic_parameters`

Summary: Update the Dynamic Domain Parameters for the domain

Arguments:

- modifier: `com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters => com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters`
- force: Boolean

Description: force: Enable potentially dangerous changes. Required to increase `ledgerTimeRecordTimeTolerance`. Use `set_ledger_time_record_time_tolerance_securely` to securely increase `ledgerTimeRecordTimeTolerance`.

28.3.4.9 Topology Administration

Topology commands run on the domain topology manager immediately affect the topology state of the domain, which means that all changes are immediately pushed to the connected participants.

`topology.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`topology.init_id`

Summary: Initialize the node with a unique identifier

Arguments:

- `identifier: com.digitalasset.canton.topology.Identifier`
- `fingerprint: com.digitalasset.canton.crypto.Fingerprint`

Return type:

- `com.digitalasset.canton.topology.UniqueIdentifier`

Description: Every node in Canton is identified using a unique identifier, which is composed of a user-chosen string and the fingerprint of a signing key. The signing key is the root key defining a so-called namespace, where the signing key has the ultimate control over issuing new identifiers. During initialisation, we have to pick such a unique identifier. By default, initialisation happens automatically, but it can be turned off by setting the `auto-init` option to `false`. Automatic node initialisation is usually turned off to preserve the identity of a participant or domain node (during major version upgrades) or if the topology transactions are managed through a different topology manager than the one integrated into this node.

`topology.load_transaction`

Summary: Upload signed topology transaction

Arguments:

- `bytes: com.google.protobuf.ByteString`

Description: Topology transactions can be issued with any topology manager. In some cases, such transactions need to be copied manually between nodes. This function allows for uploading previously exported topology transaction into the authorized store (which is the name of the topology managers transaction store).

`topology.stores.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`topology.stores.list`

Summary: List available topology stores

Return type:

- `Seq[String]`

Description: Topology transactions are stored in these stores. There are the following stores: `Authorized` - The authorized store is the store of a topology manager. Updates to the topology state are made by adding new transactions to the `Authorized` store. Both the participant and the domain nodes topology manager have such a store. A participant node will distribute all the content in the `Authorized` store to the domains it is connected to. The domain node will distribute the content of the `Authorized` store through the sequencer to the domain members in order to create the authoritative topology state

on a domain (which is stored in the store named using the domain-id), such that every domain member will have the same view on the topology state on a particular domain.

<domain-id> - The domain store is the authorized topology state on a domain. A participant has one store for each domain it is connected to. The domain has exactly one store with its domain-id. **Requested** - A domain can be configured such that when participant tries to register a topology transaction with the domain, the transaction is placed into the Requested store such that it can be analysed and processed with user defined process.

`topology.namespace_delegations.authorize`

Summary: Change namespace delegation

Arguments:

- ops: `com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- namespace: `com.digitalasset.canton.crypto.Fingerprint`
- authorizedKey: `com.digitalasset.canton.crypto.Fingerprint`
- isRootDelegation: `Boolean`
- signedBy: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- synchronize: `Option[com.digitalasset.canton.config.NonNegativeDuration]`
- force: `Boolean`

Return type:

- `com.google.protobuf.ByteString`

Description: Delegates the authority to authorize topology transactions in a certain namespace to a certain key. The keys are referred to using their fingerprints. They need to be either locally generated or have been previously imported. ops: Either Add or Remove the delegation. namespace: The namespace whose authorization authority is delegated. signedBy: Optional fingerprint of the authorizing key. The authorizing key needs to be either the authorizedKey for root certificates. Otherwise, the signedBy key needs to refer to a previously authorized key, which means that we use the signedBy key to refer to a locally available CA. authorizedKey: Fingerprint of the key to be authorized. If signedBy equals authorizedKey, then this transaction corresponds to a self-signed root certificate. If the keys differ, then we get an intermediate CA. isRootDelegation: If set to true (default = false), the authorized key will be allowed to issue NamespaceDelegations. synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

`topology.namespace_delegations.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: `String`

`topology.namespace_delegations.list`

Summary: List namespace delegation transactions

Arguments:

- filterStore: `String`
- useStateStore: `Boolean`
- timeQuery: `com.digitalasset.canton.topology.store.TimeQuery`
- operation: `Option[com.digitalasset.canton.topology.transaction.TopologyChangeOp]`
- filterNamespace: `String`
- filterSigningKey: `String`
- filterTargetKey: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- protocolVersion: `Option[String]`

Return type:

- `Seq[com.digitalasset.canton.admin.api.client.data.ListNamespaceDelegationRe-`

sult]

Description: List the namespace delegation transaction present in the stores. Namespace delegations are topology transactions that permission a key to issue topology transactions within a certain namespace. `filterStore`: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) `useStateStore`: If true (default), only properly authorized transactions that are part of the state will be selected. `timeQuery`: The time query allows to customize the query by time. The following options are supported: `TimeQuery.HeadState` (default): The most recent known state. `TimeQuery.Snapshot(ts)`: The state at a certain point in time. `TimeQuery.Range(fromO, toO)`: Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has `Add`. `filterSigningKey`: Filter for transactions that are authorized with a key that starts with the given filter string. `filterNamespace`: Filter for namespaces starting with the given filter string. `filterTargetKey`: Filter for namespaces delegations for the given target key. `protocolVersion`: Export the topology transactions in the optional protocol version.

`topology.identifier_delegations.authorize`

Summary: Change identifier delegation

Arguments:

- `ops`: `com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- `identifier`: `com.digitalasset.canton.topology.UniqueIdentifier`
- `authorizedKey`: `com.digitalasset.canton.crypto.Fingerprint`
- `signedBy`: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- `synchronize`: `Option[com.digitalasset.canton.config.NonNegativeDuration]`

Return type:

- `com.google.protobuf.ByteString`

Description: Delegates the authority of a certain identifier to a certain key. This corresponds to a normal certificate which binds identifier to a key. The keys are referred to using their fingerprints. They need to be either locally generated or have been previously imported. `ops`: Either Add or Remove the delegation. `signedBy`: Refers to the optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. `authorizedKey`: Fingerprint of the key to be authorized. `synchronize`: Synchronize timeout can be used to ensure that the state has been propagated into the node

`topology.identifier_delegations.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: `String`

`topology.identifier_delegations.list`

Summary: List identifier delegation transactions

Arguments:

- `filterStore`: `String`
- `useStateStore`: `Boolean`
- `timeQuery`: `com.digitalasset.canton.topology.store.TimeQuery`
- `operation`: `Option[com.digitalasset.canton.topology.transaction.TopologyChangeOp]`
- `filterUid`: `String`
- `filterSigningKey`: `String`
- `filterTargetKey`: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- `protocolVersion`: `Option[String]`

Return type:

- Seq[com.digitalasset.canton.admin.api.client.data.ListIdentifierDelegationResult]

Description: List the identifier delegation transaction present in the stores. Identifier delegations are topology transactions that permission a key to issue topology transactions for a certain unique identifier. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add . filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterUid: Filter for unique identifiers starting with the given filter string. protocolVersion: Export the topology transactions in the optional protocol version.

[topology.owner_to_key_mappings.authorize](#)

Summary: Change an owner to key mapping

Arguments:

- ops: com.digitalasset.canton.topology.transaction.TopologyChangeOp
- keyOwner: com.digitalasset.canton.topology.KeyOwner
- key: com.digitalasset.canton.crypto.Fingerprint
- purpose: com.digitalasset.canton.crypto.KeyPurpose
- signedBy: Option[com.digitalasset.canton.crypto.Fingerprint]
- synchronize: Option[com.digitalasset.canton.config.NonNegativeDuration]
- force: Boolean

Return type:

- com.google.protobuf.ByteString

Description: Change a owner to key mapping. A key owner is anyone in the system that needs a key-pair known to all members (participants, mediator, sequencer, topology manager) of a domain. ops: Either Add or Remove the key mapping update. signedBy: Optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. ownerType: Role of the following owner (Participant, Sequencer, Mediator, Domain-TopologyManager) owner: Unique identifier of the owner. key: Fingerprint of key purposes: The purposes of the owner to key mapping. force: removing the last key is dangerous and must therefore be manually forced synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

[topology.owner_to_key_mappings.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[topology.owner_to_key_mappings.list](#)

Summary: List owner to key mapping transactions

Arguments:

- filterStore: String
- useStateStore: Boolean
- timeQuery: com.digitalasset.canton.topology.store.TimeQuery
- operation: Option[com.digitalasset.canton.topology.transaction.TopologyChangeOp]
- filterKeyOwnerType: Option[com.digitalasset.canton.topology.KeyOwner-

Code]

- filterKeyOwnerId: String
- filterKeyPurpose: [Option\[com.digitalasset.canton.crypto.KeyPurpose\]](#)
- filterSigningKey: String
- protocolVersion: Option[String]

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListOwnerToKeyMappingResult\]](#)

Description: List the owner to key mapping transactions present in the stores. Owner to key mappings are topology transactions defining that a certain key is used by a certain key owner. Key owners are participants, sequencers, mediators and domains. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has Add . filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterKeyOwnerType: Filter for a particular type of key owner (KeyOwnerCode). filterKeyOwnerId: Filter for key owners unique identifier starting with the given filter string. filterKeyPurpose: Filter for keys with a particular purpose (Encryption or Signing) protocolVersion: Export the topology transactions in the optional protocol version.

[topology.owner_to_key_mappings.rotate_key](#)

Summary: Rotate the key for an owner to key mapping

Arguments:

- nodeInstance: [com.digitalasset.canton.console.InstanceReferenceCommon](#)
- owner: [com.digitalasset.canton.topology.KeyOwner](#)
- currentKey: [com.digitalasset.canton.crypto.PublicKey](#)
- newKey: [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates the key for an existing owner to key mapping by issuing a new owner to key mapping with the new key and removing the previous owner to key mapping with the previous key. nodeInstance: The node instance that is used to verify that both current and new key pertain to this node. This avoids conflicts when there are different nodes with the same uuid (i.e., multiple sequencers). owner: The owner of the owner to key mapping currentKey: The current public key that will be rotated newKey: The new public key that has been generated

[topology.party_to_participant_mappings.authorize \(Preview\)](#)

Summary: Change party to participant mapping

Arguments:

- ops: [com.digitalasset.canton.topology.transaction.TopologyChangeOp](#)
- party: [com.digitalasset.canton.topology.PartyId](#)
- participant: [com.digitalasset.canton.topology.ParticipantId](#)
- side: [com.digitalasset.canton.topology.transaction.RequestSide](#)
- permission: [com.digitalasset.canton.topology.transaction.ParticipantPermission](#)
- signedBy: [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- synchronize: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)
- replaceExisting: Boolean

- force: Boolean

Return type:

- com.google.protobuf.ByteString

Description: Change the association of a party to a participant. If both identifiers are in the same namespace, then the request-side is Both. If they differ, then we need to say whether the request comes from the party (RequestSide.From) or from the participant (RequestSide.To). And, we need the matching request of the other side. Please note that this is a preview feature due to the fact that inhomogeneous topologies can not yet be properly represented on the Ledger API. ops: Either Add or Remove the mapping signedBy: Refers to the optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. party: The unique identifier of the party we want to map to a participant. participant: The unique identifier of the participant to which the party is supposed to be mapped. side: The request side (RequestSide.From if we the transaction is from the perspective of the party, RequestSide.To from the participant.) privilege: The privilege of the given participant which allows us to restrict an association (e.g. Confirmation or Observation). replaceExisting: If true (default), replace any existing mapping with the new setting synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node

[topology.party_to_participant_mappings.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[topology.party_to_participant_mappings.list](#)

Summary: List party to participant mapping transactions

Arguments:

- filterStore: String
- useStateStore: Boolean
- timeQuery: [com.digitalasset.canton.topology.store.TimeQuery](#)
- operation: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- filterParty: String
- filterParticipant: String
- filterRequestSide: [Option\[com.digitalasset.canton.topology.transaction.RequestSide\]](#)
- filterPermission: [Option\[com.digitalasset.canton.topology.transaction.ParticipantPermission\]](#)
- filterSigningKey: String
- protocolVersion: [Option\[String\]](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListPartyToParticipantResult\]](#)

Description: List the party to participant mapping transactions present in the stores. Party to participant mappings are topology transactions used to allocate a party to a certain participant. The same party can be allocated on several participants with different privileges. A party to participant mapping has a request-side that identifies whether the mapping is authorized by the party, by the participant or by both. In order to have a party be allocated to a given participant, we therefore need either two transactions (one with RequestSide.From, one with RequestSide.To) or one with RequestSide.Both. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are

part of the state will be selected. `timeQuery`: The time query allows to customize the query by time. The following options are supported: `TimeQuery.HeadState` (default): The most recent known state. `TimeQuery.Snapshot(ts)`: The state at a certain point in time. `TimeQuery.Range(fromO, toO)`: Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has `Add`. `filterSigningKey`: Filter for transactions that are authorized with a key that starts with the given filter string. `filterParty`: Filter for parties starting with the given filter string. `filterParticipant`: Filter for participants starting with the given filter string. `filterRequestSide`: Optional filter for a particular request side (Both, From, To). `protocolVersion`: Export the topology transactions in the optional protocol version.

`topology.participant_domain_states.active`

Summary: Returns true if the given participant is currently active on the given domain

Arguments:

- `domainId`: `com.digitalasset.canton.topology.DomainId`
- `participantId`: `com.digitalasset.canton.topology.ParticipantId`

Return type:

- `Boolean`

Description: Active means that the participant has been granted at least observation rights on the domain and that the participant has registered a domain trust certificate

`topology.participant_domain_states.authorize`

Summary: Change participant domain states

Arguments:

- `ops`: `com.digitalasset.canton.topology.transaction.TopologyChangeOp`
- `domain`: `com.digitalasset.canton.topology.DomainId`
- `participant`: `com.digitalasset.canton.topology.ParticipantId`
- `side`: `com.digitalasset.canton.topology.transaction.RequestSide`
- `permission`: `com.digitalasset.canton.topology.transaction.ParticipantPermission`
- `trustLevel`: `com.digitalasset.canton.topology.transaction.TrustLevel`
- `signedBy`: `Option[com.digitalasset.canton.crypto.Fingerprint]`
- `synchronize`: `Option[com.digitalasset.canton.config.NonNegativeDuration]`
- `replaceExisting`: `Boolean`

Return type:

- `com.google.protobuf.ByteString`

Description: Change the association of a participant to a domain. In order to activate a participant on a domain, we need both authorisation: the participant authorising its uid to be present on a particular domain and the domain to authorise the presence of a participant on said domain. If both identifiers are in the same namespace, then the request-side can be Both. If they differ, then we need to say whether the request comes from the domain (`RequestSide.From`) or from the participant (`RequestSide.To`). And, we need the matching request of the other side. `ops`: Either Add or Remove the mapping `signedBy`: Refers to the optional fingerprint of the authorizing key which in turn refers to a specific, locally existing certificate. `domain`: The unique identifier of the domain we want the participant to join. `participant`: The unique identifier of the participant. `side`: The request side (`RequestSide.From` if we the transaction is from the perspective of the domain, `RequestSide.To` from the participant.) `permission`: The privilege of the given participant which allows us to restrict an association (e.g. Confirmation or Observation). Will use the lower of if different between To/From. `trustLevel`: The trust level of the participant on the given domain. Will use the lower of if different between To/From. `replaceExisting`: If true (default), replace any existing mapping with the new setting `synchronize`: Synchronize timeout can be used to

ensure that the state has been propagated into the node

`topology.participant_domain_states.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`topology.participant_domain_states.list`

Summary: List participant domain states

Arguments:

- `filterStore`: String
- `useStateStore`: Boolean
- `timeQuery`: [com.digitalasset.canton.topology.store.TimeQuery](#)
- `operation`: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- `filterDomain`: String
- `filterParticipant`: String
- `filterSigningKey`: String
- `protocolVersion`: [Option\[String\]](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListParticipantDomainStateResult\]](#)

Description: List the participant domain transactions present in the stores. Participant domain states are topology transactions used to permission a participant on a given domain. A participant domain state has a request-side that identifies whether the mapping is authorized by the participant (From), by the domain (To) or by both (Both). In order to use a participant on a domain, both have to authorize such a mapping. This means that by authorizing such a topology transaction, a participant acknowledges its presence on a domain, whereas a domain permissions the participant on that domain. `filterStore`: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) `useStateStore`: If true (default), only properly authorized transactions that are part of the state will be selected. `timeQuery`: The time query allows to customize the query by time. The following options are supported: `TimeQuery.HeadState` (default): The most recent known state. `TimeQuery.Snapshot(ts)`: The state at a certain point in time. `TimeQuery.Range(fromO, toO)`: Time-range of when the transaction was added to the store `operation`: Optionally, what type of operation the transaction should have. State store only has `Add`. `filterSigningKey`: Filter for transactions that are authorized with a key that starts with the given filter string. `filterDomain`: Filter for domains starting with the given filter string. `filterParticipant`: Filter for participants starting with the given filter string. `protocolVersion`: Export the topology transactions in the optional protocol version.

`topology.vetted_packages.authorize`

Summary: Change package vettings

Arguments:

- `ops`: [com.digitalasset.canton.topology.transaction.TopologyChangeOp](#)
- `participant`: [com.digitalasset.canton.topology.ParticipantId](#)
- `packageIds`: [Seq\[com.daml.lf.data.Ref.PackageId\]](#)
- `signedBy`: [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- `synchronize`: [Option\[com.digitalasset.canton.config.NonNegativeDuration\]](#)
- `force`: Boolean

Return type:

- [com.google.protobuf.ByteString](#)

Description: A participant will only process transactions that reference packages that all involved participants have vetted previously. Vetting is done by registering a respective topology transaction with the domain, which can then be used by other participants to verify that a transaction is only using vetted packages. Note that all referenced and dependent packages must exist in the package store. By default, only vetting transactions adding new packages can be issued. Removing package vettings and issuing package vettings for other participants (if their identity is controlled through this participants topology manager) or for packages that do not exist locally can only be run using the `force = true` flag. However, these operations are dangerous and can lead to the situation of a participant being unable to process transactions. ops: Either Add or Remove the vetting. participant: The unique identifier of the participant that is vetting the package. packageIds: The If-package ids to be vetted. signedBy: Refers to the fingerprint of the authorizing key which in turn must be authorized by a valid, locally existing certificate. If none is given, a key is automatically determined. synchronize: Synchronize timeout can be used to ensure that the state has been propagated into the node force: Flag to enable dangerous operations (default false). Great power requires great care.

[topology.vetted_packages.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

[topology.vetted_packages.list](#)

Summary: List package vetting transactions

Arguments:

- `filterStore: String`
- `useStateStore: Boolean`
- `timeQuery: com.digitalasset.canton.topology.store.TimeQuery`
- `operation: Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]`
- `filterParticipant: String`
- `filterSigningKey: String`
- `protocolVersion: Option[String]`

Return type:

- `Seq\[com.digitalasset.canton.admin.api.client.data.ListVettedPackagesResult\]`

Description: List the package vetting transactions present in the stores. Participants must vet Daml packages and submitters must ensure that the receiving participants have vetted the package prior to submitting a transaction (done automatically during submission and validation). Vetting is done by authorizing such topology transactions and registering with a domain. filterStore: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) useStateStore: If true (default), only properly authorized transactions that are part of the state will be selected. timeQuery: The time query allows to customize the query by time. The following options are supported: TimeQuery.HeadState (default): The most recent known state. TimeQuery.Snapshot(ts): The state at a certain point in time. TimeQuery.Range(fromO, toO): Time-range of when the transaction was added to the store operation: Optionally, what type of operation the transaction should have. State store only has `Add`. filterSigningKey: Filter for transactions that are authorized with a key that starts with the given filter string. filterParticipant: Filter for participants starting with the given filter string. protocolVersion: Export the topology transactions in the optional protocol version.

[topology.all.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`topology.all.list`

Summary: List all transaction

Arguments:

- `filterStore`: String
- `useStateStore`: Boolean
- `timeQuery`: [com.digitalasset.canton.topology.store.TimeQuery](#)
- `operation`: [Option\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)
- `filterAuthorizedKey`: [Option\[com.digitalasset.canton.crypto.Fingerprint\]](#)
- `protocolVersion`: [Option\[String\]](#)

Return type:

- [com.digitalasset.canton.topology.store.StoredTopologyTransactions\[com.digitalasset.canton.topology.transaction.TopologyChangeOp\]](#)

Description: List all topology transactions in a store, independent of the particular type. This method is useful for exporting entire states. `filterStore`: Filter for topology stores starting with the given filter string (Authorized, <domain-id>, Requested) `useStateStore`: If true (default), only properly authorized transactions that are part of the state will be selected. `timeQuery`: The time query allows to customize the query by time. The following options are supported: `TimeQuery.HeadState` (default): The most recent known state. `TimeQuery.Snapshot(ts)`: The state at a certain point in time. `TimeQuery.Range(from0, to0)`: Time-range of when the transaction was added to the store `operation`: Optionally, what type of operation the transaction should have. State store only has `Add`. `filterAuthorizedKey`: Filter the topology transactions by the key that has authorized the transactions. `protocolVersion`: Export the topology transactions in the optional protocol version.

`topology.all.renew`

Summary: Renew all topology transactions that have been authorized with a previous key using a new key

Arguments:

- `filterAuthorizedKey`: [com.digitalasset.canton.crypto.Fingerprint](#)
- `authorizeWith`: [com.digitalasset.canton.crypto.Fingerprint](#)

Description: Finds all topology transactions that have been authorized by `filterAuthorizedKey` and renews those topology transactions by authorizing them with the new key `authorizeWith`. `filterAuthorizedKey`: Filter the topology transactions by the key that has authorized the transactions. `authorizeWith`: The key to authorize the renewed topology transactions.

28.3.5 Domain Manager Administration Commands

`clear_cache (Testing)`

Summary: Clear locally cached variables

Description: Some commands cache values on the client side. Use this command to explicitly clear the caches of these values.

`config`

Summary: Returns the domain configuration

Return type:

- [com.digitalasset.canton.domain.config.DomainManagerConfig](#)

help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

id

Summary: Yields the globally unique id of this domain. Throws an exception, if the id has not yet been allocated (e.g., the domain has not yet been started).

Return type:

- [com.digitalasset.canton.topology.DomainId](#)

is_initialized

Summary: Check if the local instance is running and is fully initialized

Return type:

- Boolean

is_running

Summary: Check if the local instance is running

Return type:

- Boolean

start

Summary: Start the instance

stop

Summary: Stop the instance

28.3.5.1 Setup**setup.authorize_mediator**

Summary: Authorize external Mediator node.

Arguments:

- `mediatorId`: [com.digitalasset.canton.topology.MediatorId](#)

Description: Use this command to reinstate an external mediator node that has been offboarded via `offboard_mediator`.

setup.bootstrap_domain

Summary: Bootstrap domain

Arguments:

- `sequencers`: [Seq\[com.digitalasset.canton.console.SequencerNodeReference\]](#)
- `mediators`: [Seq\[com.digitalasset.canton.console.MediatorReference\]](#)

Description: Use this command to bootstrap the domain with an initial set of external sequencer(s) and external mediator(s). Note that you only need to call this once, however it is safe to call it again if necessary in case something went wrong and this needs to be retried.

setup.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

setup.init

Summary: Initialize domain

Arguments:

- sequencerConnection: [com.digitalasset.canton.sequencing.SequencerConnection](#)

Description: This command triggers domain initialization and should be called once the initial topology data has been authorized and sequenced. This is called as part of the setup.bootstrap command, so you are unlikely to need to call this directly.

setup.init

Summary: Initialize domain

Arguments:

- sequencerConnections: [com.digitalasset.canton.sequencing.SequencerConnections](#)

Description: This command triggers domain initialization and should be called once the initial topology data has been authorized and sequenced. This is called as part of the setup.bootstrap command, so you are unlikely to need to call this directly.

setup.offboard_mediator

Summary: Offboard external Mediator node.

Arguments:

- mediatorId: [com.digitalasset.canton.topology.MediatorId](#)
- force: Boolean

Description: Use this command to offboard an onboarded external mediator node. It removes the topology transaction that authorizes the given mediator ID to act as a mediator on the domain. If you afterwards want to authorize an offboarded mediator again, use authorize_mediator. You must apply force to offboard the last mediator of a domain.

setup.onboard_mediator

Summary: Onboard external Mediator node.

Arguments:

- mediator: [com.digitalasset.canton.console.MediatorReference](#)
- sequencerConnections: [Seq\[com.digitalasset.canton.console.InstanceReferenceWithSequencerConnection\]](#)

Description: Use this command to onboard an external mediator node. If you're bootstrapping a domain with external sequencer(s) and this is the initial mediator, then use setup.bootstrap_domain instead. For adding additional external mediators or onboard an external mediator with a domain that runs a single embedded sequencer, use this command. Note that you only need to call this once.

setup.onboard_new_sequencer

Summary: Dynamically onboard new Sequencer node.

Arguments:

- initialSequencer: [com.digitalasset.canton.console.SequencerNodeReference](#)
- newSequencer: [com.digitalasset.canton.console.SequencerNodeReference](#)

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Use this command to dynamically onboard a new sequencer node that's not part of the initial set of sequencer nodes. Do not use this for database sequencers.

28.3.5.2 Health

`health.active`

Summary: Check if the node is running and is the active instance (mediator, participant)

Return type:

- Boolean

`health.dump`

Summary: Creates a zip file containing diagnostic information about the canton process running this node

Arguments:

- `outputFile`: `better.files.File`
- `timeout`: `com.digitalasset.canton.config.NonNegativeDuration`
- `chunkSize`: `Option[Int]`

Return type:

- String

`health.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`health.initialized`

Summary: Returns true if node has been initialized.

Return type:

- Boolean

`health.last_error_trace`

Summary: Show all messages logged with the given `traceId` in a recent interval

Arguments:

- `traceId`: String

Return type:

- `Seq[String]`

Description: Returns a list of buffered log messages associated to a given trace-id. Usually, the trace-id is taken from `last_errors()`

`health.last_errors`

Summary: Show the last errors logged

Return type:

- `Map[String,String]`

Description: Returns a map with the trace-id as key and the most recent error messages as value. Requires that `-log-last-errors` is enabled (and not turned off).

`health.running`

Summary: Check if the node is running

Return type:

- Boolean

`health.set_log_level`

Summary: Change the log level of the process

Arguments:

- `level`: `ch.qos.logback.classic.Level`

Description: If the default logback configuration is used, this will change the log level of the process.

`health.status`

Summary: Get human (and machine) readable participant status information

Return type:

- `com.digitalasset.canton.admin.api.client.data.NodeStatus[S]`

`health.wait_for_identity`

Summary: Wait for the node to have an identity

Description: This is specifically useful for the Domain Manager which needs its identity to be ready for bootstrapping, but for which we can't rely on `wait_for_initialized()` because it will be initialized only after being bootstrapped.

`health.wait_for_initialized`

Summary: Wait for the node to be initialized

`health.wait_for_running`

Summary: Wait for the node to be running

28.3.5.3 Database

`db.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`db.migrate`

Summary: Migrates the instance's database if using a database storage

Description: When instances reside on different nodes, their database migration can be run in parallel to save time. Please note that the migration commands must however be run on each node individually, because remote migration through `participants.remote` is not supported.

`db.repair_migration`

Summary: Only use when advised - repairs the database migration of the instance's database

Arguments:

- `force: Boolean`

Description: In some rare cases, we change already applied database migration files in a new release and the repair command resets the checksums we use to ensure that in general already applied migration files have not been changed. You should only use `db.repair_migration` when advised and otherwise use it at your own risk - in the worst case running it may lead to data corruption when an incompatible database migration (one that should be rejected because the already applied database migration files have changed) is subsequently falsely applied.

28.3.5.4 Sequencer Connection

`sequencer_connection.get`

Summary: Get Sequencer Connection

Return type:

- `Option[com.digitalasset.canton.sequencing.SequencerConnections]`

Description: Use this command to get the currently configured sequencer connection details for this sequencer client. If this node has not yet been initialized, this will return `None`.

`sequencer_connection.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`sequencer_connection.modify`

Summary: Modify Default Sequencer Connection

Arguments:

- `modifier: com.digitalasset.canton.sequencing.SequencerConnection => com.digitalasset.canton.sequencing.SequencerConnection`

Description: Modify sequencer connection details for this sequencer client node, by passing a modifier function that operates on the existing default connection.

`sequencer_connection.modify_connections`

Summary: Modify Sequencer Connections

Arguments:

- `modifier: com.digitalasset.canton.sequencing.SequencerConnections => com.digitalasset.canton.sequencing.SequencerConnections`

Description: Modify sequencer connection details for this sequencer client node, by passing a modifier function that operates on the existing connection configuration.

`sequencer_connection.set`

Summary: Set Sequencer Connection

Arguments:

- `connection: com.digitalasset.canton.sequencing.SequencerConnection`

Description: Set new sequencer connection details for this sequencer client node. This will replace any pre-configured connection details. This command will only work after the node has been initialized.

`sequencer_connection.set`

Summary: Set Sequencer Connection

Arguments:

- `connections: com.digitalasset.canton.sequencing.SequencerConnections`

Description: Set new sequencer connection details for this sequencer client node. This will replace any pre-configured connection details. This command will only work after the node has been initialized.

28.3.5.5 Key Administration

`keys.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`keys.public.download`

Summary: Download public key

Arguments:

- `fingerprint`: [com.digitalasset.canton.crypto.Fingerprint](#)
- `protocolVersion`: [com.digitalasset.canton.version.ProtocolVersion](#)

Return type:

- `com.google.protobuf.ByteString`

`keys.public.download_to`

Summary: Download public key and save it to a file

Arguments:

- `fingerprint`: [com.digitalasset.canton.crypto.Fingerprint](#)
- `outputFile`: String
- `protocolVersion`: [com.digitalasset.canton.version.ProtocolVersion](#)

`keys.public.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`keys.public.list`

Summary: List public keys in registry

Arguments:

- `filterFingerprint`: String
- `filterContext`: String

Return type:

- [Seq\[com.digitalasset.canton.crypto.PublicKeyWithName\]](#)

Description: Returns all public keys that have been added to the key registry. Optional arguments can be used for filtering.

`keys.public.list_by_owner`

Summary: List keys for given keyOwner.

Arguments:

- `keyOwner`: [com.digitalasset.canton.topology.KeyOwner](#)
- `filterDomain`: String
- `asOf`: `Option[java.time.Instant]`
- `limit`: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListKeyOwnersResult\]](#)

Description: This command is a convenience wrapper for `list_key_owners`, taking an explicit `keyOwner` as search argument. The response includes the public keys.

`keys.public.list_owners`

Summary: List active owners with keys for given search arguments.

Arguments:

- filterKeyOwnerUid: String
- filterKeyOwnerType: [Option\[com.digitalasset.canton.topology.KeyOwner-Code\]](#)
- filterDomain: String
- asOf: Option[[java.time.Instant](#)]
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListKeyOwnersResult\]](#)

Description: This command allows deep inspection of the topology state. The response includes the public keys. Optional filterKeyOwnerType type can be 'ParticipantId.Code', 'MediatorId.Code', 'SequencerId.Code', 'DomainTopologyManagerId.Code'.

keys.public.upload

Summary: Upload public key

Arguments:

- filename: String
- name: Option[String]

Return type:

- [com.digitalasset.canton.crypto.Fingerprint](#)

keys.public.upload

Summary: Upload public key

Arguments:

- keyBytes: [com.google.protobuf.ByteString](#)
- name: Option[String]

Return type:

- [com.digitalasset.canton.crypto.Fingerprint](#)

Description: Import a public key and store it together with a name used to provide some context to that key.

keys.secret.delete

Summary: Delete private key

Arguments:

- fingerprint: [com.digitalasset.canton.crypto.Fingerprint](#)
- force: Boolean

keys.secret.download

Summary: Download key pair

Arguments:

- fingerprint: [com.digitalasset.canton.crypto.Fingerprint](#)
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)

Return type:

- [com.google.protobuf.ByteString](#)

keys.secret.download_to

Summary: Download key pair and save it to a file

Arguments:

- fingerprint: [com.digitalasset.canton.crypto.Fingerprint](#)
- outputFile: String
- protocolVersion: [com.digitalasset.canton.version.ProtocolVersion](#)

keys.secret.generate_encryption_key

Summary: Generate new public/private key pair for encryption and store it in the vault

Arguments:

- name: String
- scheme: [Option\[com.digitalasset.canton.crypto.EncryptionKeyScheme\]](#)

Return type:

- [com.digitalasset.canton.crypto.EncryptionPublicKey](#)

Description: The optional name argument allows you to store an associated string for your convenience. The scheme can be used to select a key scheme and the default scheme is used if left unspecified.

[keys.secret.generate_signing_key](#)

Summary: Generate new public/private key pair for signing and store it in the vault

Arguments:

- name: String
- scheme: [Option\[com.digitalasset.canton.crypto.SigningKeyScheme\]](#)

Return type:

- [com.digitalasset.canton.crypto.SigningPublicKey](#)

Description: The optional name argument allows you to store an associated string for your convenience. The scheme can be used to select a key scheme and the default scheme is used if left unspecified.

[keys.secret.get_wrapper_key_id](#)

Summary: Get the wrapper key id that is used for the encrypted private keys store

Return type:

- String

[keys.secret.help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

[keys.secret.list](#)

Summary: List keys in private vault

Arguments:

- filterFingerprint: String
- filterName: String
- purpose: [Set\[com.digitalasset.canton.crypto.KeyPurpose\]](#)

Return type:

- [Seq\[com.digitalasset.canton.crypto.admin.grpc.PrivateKeyMetadata\]](#)

Description: Returns all public keys to the corresponding private keys in the key vault. Optional arguments can be used for filtering.

[keys.secret.register_kms_encryption_key](#)

Summary: Register the specified KMS encryption key in canton storing its public information in the vault

Arguments:

- kmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.EncryptionPublicKey](#)

Description: The id for the KMS encryption key. The optional name argument allows you to store an associated string for your convenience.

[keys.secret.register_kms_signing_key](#)

Summary: Register the specified KMS signing key in canton storing its public information

in the vault

Arguments:

- kmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.SigningPublicKey](#)

Description: The id for the KMS signing key. The optional name argument allows you to store an associated string for your convenience.

[keys.secret.rotate_kms_node_key](#)

Summary: Rotate a given node's keypair with a new pre-generated KMS keypair

Arguments:

- fingerprint: String
- newKmsKeyId: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates an existing encryption or signing key stored externally in a KMS with a pre-generated key. For a sequencer or mediator node use `rotate_kms_node_key` with a domain manager reference as an argument. The fingerprint of the key we want to rotate. The id of the new KMS key (e.g. Resource Name). An optional name for the new key.

[keys.secret.rotate_node_key](#)

Summary: Rotate a node's public/private key pair

Arguments:

- fingerprint: String
- name: String

Return type:

- [com.digitalasset.canton.crypto.PublicKey](#)

Description: Rotates an existing encryption or signing key. NOTE: A namespace root or intermediate signing key CANNOT be rotated by this command. For a sequencer or mediator node use `rotate_kms_node_key` with a domain manager reference as an argument. The fingerprint of the key we want to rotate. An optional name for the new key.

[keys.secret.rotate_node_keys](#)

Summary: Rotate the node's public/private key pairs

Description: For a participant node it rotates the signing and encryption key pair. For a domain or domain manager node it rotates the signing key pair as those nodes do not have an encryption key pair. For a sequencer or mediator node use `rotate_node_keys` with a domain manager reference as an argument. NOTE: Namespace root or intermediate signing keys are NOT rotated by this command.

[keys.secret.rotate_wrapper_key](#)

Summary: Change the wrapper key for encrypted private keys store

Arguments:

- newWrapperKeyId: String

Description: Change the wrapper key (e.g. AWS KMS key) being used to encrypt the private keys in the store. `newWrapperKeyId`: The optional new wrapper key id to be used. If the wrapper key id is empty Canton will generate a new key based on the current configuration.

[keys.secret.upload](#)

Summary: Upload a key pair

Arguments:

- pairBytes: `com.google.protobuf.ByteString`

- name: Option[String]

[keys.secret.upload](#)

Summary: Upload (load and import) a key pair from file

Arguments:

- filename: String
- name: Option[String]

28.3.5.6 Parties

[parties.help](#)

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

[parties.list](#)

Summary: List active parties, their active participants, and the participants' permissions on domains.

Arguments:

- filterParty: String
- filterParticipant: String
- filterDomain: String
- asOf: Option[java.time.Instant]
- limit: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Seq\[com.digitalasset.canton.admin.api.client.data.ListPartiesResult\]](#)

Description: Inspect the parties known by this participant as used for synchronisation. The response is built from the timestamped topology transactions of each domain, excluding the authorized store of the given node. For each known party, the list of active participants and their permission on the domain for that party is given. filterParty: Filter by parties starting with the given string. filterParticipant: Filter for parties that are hosted by a participant with an id starting with the given string filterDomain: Filter by domains whose id starts with the given string. asOf: Optional timestamp to inspect the topology state at a given point in time. limit: Limit on the number of parties fetched (defaults to `canton.parameters.console.default-limit`). Example: `participant1.parties.list(filterParty= alice)`

28.3.5.7 Service

[service.get_dynamic_domain_parameters](#)

Summary: Get the Dynamic Domain Parameters configured for the domain

Return type:

- [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#)

[service.get_max_rate_per_participant](#)

Summary: Get the max rate per participant

Return type:

- [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

Description: Depending on the protocol version used on the domain, the value will be read either from the static domain parameters or the dynamic ones.

service.get_max_request_size**Summary:** Get the max request size**Return type:**

- [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

Description: Depending on the protocol version used on the domain, the value will be read either from the static domain parameters or the dynamic ones. This value is not necessarily the one used by the sequencer node because it requires a restart of the server to be taken into account.

service.get_mediator_deduplication_timeout**Summary:** Get the mediator deduplication timeout**Return type:**

- [com.digitalasset.canton.config.NonNegativeFiniteDuration](#)

Description: The method will fail, if the domain does not support the mediatorDeduplicationTimeout.

service.get_reconciliation_interval**Summary:** Get the reconciliation interval configured for the domain**Return type:**

- [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: Depending on the protocol version used on the domain, the value will be read either from the static domain parameters or the dynamic ones.

service.get_static_domain_parameters**Summary:** Get the Static Domain Parameters configured for the domain**Return type:**

- [com.digitalasset.canton.admin.api.client.data.StaticDomainParameters](#)

service.help

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

service.list_accepted_agreements**Summary:** List the accepted service agreements**Return type:**

- [Seq\[com.digitalasset.canton.domain.service.ServiceAgreementAcceptance\]](#)

service.set_commitments_catch_up_config**Summary:** Update the ACS commitments catch up config for the domain**Arguments:**

- config: [com.digitalasset.canton.protocol.CatchUpConfig](#)

Description: The method will fail if the domain does not support the catchUpConfig parameter (i.e., if the domain is running on protocol version lower than 6)

service.set_dynamic_domain_parameters**Summary:** Set the Dynamic Domain Parameters configured for the domain**Arguments:**

- dynamicDomainParameters: [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#)
- force: Boolean

Description: force: Enable potentially dangerous changes. Required to increase ledgerTimeRecordTimeTolerance. Use set_ledger_time_record_time_tolerance to securely increase ledgerTimeRecordTimeTolerance.

`service.set_ledger_time_record_time_tolerance`

Summary: Update the `ledgerTimeRecordTimeTolerance` in the dynamic domain parameters.

Arguments:

- `newLedgerTimeRecordTimeTolerance`: [com.digitalasset.canton.config.NonNegativeFiniteDuration](#)
- `force`: Boolean

Description: If it would be insecure to perform the change immediately, the command will block and wait until it is secure to perform the change. The command will block for at most twice of `newLedgerTimeRecordTimeTolerance`. If the domain does not support `mediatorDeduplicationTimeout`, the method will update `ledgerTimeRecordTimeTolerance` immediately without blocking. The method will fail if `mediatorDeduplicationTimeout` is less than twice of `newLedgerTimeRecordTimeTolerance`. Do not modify domain parameters concurrently while running this command, because the command may override concurrent changes. `force`: update `ledgerTimeRecordTimeTolerance` immediately without blocking. This is safe to do during domain bootstrapping and in test environments, but should not be done in operational production systems..

`service.set_max_inbound_message_size`

Summary: Try to update the max rate per participant for the domain

Arguments:

- `maxRequestSize`: [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)
- `force`: Boolean

Description: If the max request size is dynamic, update the value. The update won't have any effect unless the sequencer server is restarted. If the max request size is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

`service.set_max_rate_per_participant`

Summary: Try to update the max rate per participant for the domain

Arguments:

- `maxRatePerParticipant`: [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)

Description: If the max rate per participant is dynamic, update the value. If the max rate per participant is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

`service.set_max_request_size`

Summary: Try to update the max rate per participant for the domain

Arguments:

- `maxRequestSize`: [com.digitalasset.canton.config.RequireTypes.NonNegativeInt](#)
- `force`: Boolean

Description: If the max request size is dynamic, update the value. The update won't have any effect unless the sequencer server is restarted. If the max request size is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

`service.set_mediator_deduplication_timeout`

Summary: Update the mediator deduplication timeout

Arguments:

- `newMediatorDeduplicationTimeout`: [com.digitalasset.canton.config.NonNegativeFiniteDuration](#)

Description: The method will fail: - if the domain does not support the `mediatorDeduplicationTimeout` parameter, - if the new value of `mediatorDeduplicationTimeout` is less than twice the value of `ledgerTimeRecordTimeTolerance`.

`service.set_reconciliation_interval`

Summary: Try to update the reconciliation interval for the domain

Arguments:

- newReconciliationInterval: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: If the reconciliation interval is dynamic, update the value. If the reconciliation interval is not dynamic (i.e., if the domain is running on protocol version lower than 4), then it will throw an error.

[service.update_dynamic_domain_parameters](#)

Summary: Update the Dynamic Domain Parameters for the domain

Arguments:

- modifier: [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#) => [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#)
- force: Boolean

Description: force: Enable potentially dangerous changes. Required to increase ledgerTimeRecordTimeTolerance. Use `set_ledger_time_record_time_tolerance_securely` to securely increase ledgerTimeRecordTimeTolerance.

[service.update_dynamic_parameters](#)

Summary: Update the Dynamic Domain Parameters for the domain

Arguments:

- modifier: [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#) => [com.digitalasset.canton.admin.api.client.data.DynamicDomainParameters](#)
- force: Boolean

Description: force: Enable potentially dangerous changes. Required to increase ledgerTimeRecordTimeTolerance. Use `set_ledger_time_record_time_tolerance_securely` to securely increase ledgerTimeRecordTimeTolerance.

28.3.5.8 Topology Administration

Same as [Domain Topology Administration](#).

28.3.6 Sequencer Administration Commands

[clear_cache \(Testing\)](#)

Summary: Clear locally cached variables

Description: Some commands cache values on the client side. Use this command to explicitly clear the caches of these values.

[config](#)

Summary: Returns the sequencer configuration

Return type:

- [com.digitalasset.canton.domain.sequencing.config.SequencerNodeConfig](#)

[help](#)

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

id

Summary: Yields the globally unique id of this sequencer. Throws an exception, if the id has not yet been allocated (e.g., the sequencer has not yet been started).

Return type:

- [com.digitalasset.canton.topology.SequencerId](#)

is_initialized

Summary: Check if the local instance is running and is fully initialized

Return type:

- Boolean

is_running

Summary: Check if the local instance is running

Return type:

- Boolean

start

Summary: Start the instance

stop

Summary: Stop the instance

28.3.6.1 Sequencer

sequencer.disable_member

Summary: Disable the provided member at the Sequencer that will allow any unread data for them to be removed

Arguments:

- member: [com.digitalasset.canton.topology.Member](#)

Description: This will prevent any client for the given member to reconnect the Sequencer and allow any unread/unacknowledged data they have to be removed. This should only be used if the domain operation is confident the member will never need to reconnect as there is no way to re-enable the member. To view members using the sequencer run `sequencer.status()`.

sequencer.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- methodName: String

sequencer.pruning.clear_schedule

Summary: Deactivate automatic pruning.

sequencer.pruning.force_prune

Summary: Force remove data from the Sequencer including data that may have not been read by offline clients

Arguments:

- dryRun: Boolean

Return type:

- String

Description: Will force pruning up until the default retention period by potentially disabling clients that have not yet read data we would like to remove. Disabling these clients will prevent them from ever reconnecting to the Domain so should only be used if the

Domain operator is confident they can be permanently ignored. Run with *dryRun = true* to review a description of which clients will be disabled first. Run with *dryRun = false* to disable these clients and perform a forced pruning.

`sequencer.pruning.force_prune_at`

Summary: Force removing data from the Sequencer including data that may have not been read by offline clients up until the specified time

Arguments:

- `timestamp`: [com.digitalasset.canton.data.CantonTimestamp](#)
- `dryRun`: Boolean

Return type:

- String

Description: Similar to the above *force_prune* command but allows specifying the exact time at which to prune

`sequencer.pruning.force_prune_with_retention_period`

Summary: Force removing data from the Sequencer including data that may have not been read by offline clients up until a custom retention period

Arguments:

- `retentionPeriod`: [scala.concurrent.duration.FiniteDuration](#)
- `dryRun`: Boolean

Return type:

- String

Description: Similar to the above *force_prune* command but allows specifying a custom retention period

`sequencer.pruning.get_schedule`

Summary: Inspect the automatic pruning schedule.

Return type:

- [Option\[com.digitalasset.canton.admin.api.client.data.PruningSchedule\]](#)

Description: The schedule consists of a `cron` expression and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period. Returns *None* if no schedule has been configured via *set_schedule* or if *clear_schedule* has been invoked.

`sequencer.pruning.help`

Summary: Help for specific commands (use *help()* or *help(method)* for more information)

Arguments:

- `methodName`: String

`sequencer.pruning.locate_pruning_timestamp`

Summary: Obtain a timestamp at or near the beginning of sequencer state

Arguments:

- `index`: [com.digitalasset.canton.config.RequireTypes.PositiveInt](#)

Return type:

- [Option\[com.digitalasset.canton.data.CantonTimestamp\]](#)

Description: This command provides insight into the current state of sequencer pruning when called with the default value of *index* 1. When pruning the sequencer manually via *prune_at* and with the intent to prune in batches, specify a value such as 1000 to obtain a pruning timestamp that corresponds to the `end` of the batch.

`sequencer.pruning.prune`

Summary: Remove unnecessary data from the Sequencer up until the default retention point

Return type:

- String

Description: Removes unnecessary data from the Sequencer that is earlier than the default retention period. The default retention period is set in the configuration of the canton processing running this command under `parameters.retention-period-defaults.sequencer`. This pruning command requires that data is read and acknowledged by clients before considering it safe to remove. If no data is being removed it could indicate that clients are not reading or acknowledging data in a timely fashion (typically due to nodes going offline for long periods). You have the option of disabling the members running on these nodes to allow removal of this data, however this will mean that they will be unable to reconnect to the domain in the future. To do this run `force_prune(dryRun = true)` to return a description of which members would be disabled in order to prune the Sequencer. If you are happy to disable the described clients then run `force_prune(dryRun = false)` to permanently remove their unread data. Once offline clients have been disabled you can continue to run `prune` normally.

`sequencer.pruning.prune_at`

Summary: Remove data that has been read up until the specified time

Arguments:

- timestamp: `com.digitalasset.canton.data.CantonTimestamp`

Return type:

- String

Description: Similar to the above `prune` command but allows specifying the exact time at which to prune. The command will fail if a client has not yet read and acknowledged some data up to the specified time.

`sequencer.pruning.prune_with_retention_period`

Summary: Remove data that has been read up until a custom retention period

Arguments:

- retentionPeriod: `scala.concurrent.duration.FiniteDuration`

Return type:

- String

Description: Similar to the above `prune` command but allows specifying a custom retention period

`sequencer.pruning.set_cron`

Summary: Modify the cron used by automatic pruning.

Arguments:

- cron: String

Description: The schedule is specified in cron format and refers to pruning start times in the GMT time zone. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`sequencer.pruning.set_max_duration`

Summary: Modify the maximum duration used by automatic pruning.

Arguments:

- maxDuration: `com.digitalasset.canton.config.PositiveDurationSeconds`

Description: The *maxDuration* is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via *set_schedule* or if automatic pruning has been disabled via *clear_schedule*. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

[sequencer.pruning.set_retention](#)

Summary: Update the pruning retention used by automatic pruning.

Arguments:

- retention: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The *retention* is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via *set_schedule* or if automatic pruning has been disabled via *clear_schedule*. Additionally if at the time of this update, pruning is actively running, a best effort is made to pause pruning and restart with the newly specified retention. This allows for the case that the new retention mandates retaining more data than previously.

[sequencer.pruning.set_schedule](#)

Summary: Activate automatic pruning according to the specified schedule.

Arguments:

- cron: String
- maxDuration: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- retention: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The schedule is specified in cron format and *max_duration* and *retention* durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period.

[sequencer.pruning.status](#)

Summary: Status of the sequencer and its connected clients

Return type:

- [com.digitalasset.canton.domain.sequencing.sequencer.SequencerPruningStatus](#)

Description: Provides a detailed breakdown of information required for pruning: - the current time according to this sequencer instance - domain members that the sequencer supports - for each member when they were registered and whether they are enabled - a list of clients for each member, their last acknowledgement, and whether they are enabled

28.3.6.2 Health

[health.active](#)

Summary: Check if the node is running and is the active instance (mediator, participant)

Return type:

- Boolean

[health.dump](#)

Summary: Creates a zip file containing diagnostic information about the canton process running this node

Arguments:

- outputFile: [better.files.File](#)
- timeout: [com.digitalasset.canton.config.NonNegativeDuration](#)
- chunkSize: Option[Int]

Return type:

- String

health.has_identity

Summary: Returns true if the node has an identity

Return type:

- Boolean

health.help

Summary: Help for specific commands (use help() or help(method) for more information)

Arguments:

- methodName: String

health.initialized

Summary: Returns true if node has been initialized.

Return type:

- Boolean

health.last_error_trace

Summary: Show all messages logged with the given traceId in a recent interval

Arguments:

- traceId: String

Return type:

- Seq[String]

Description: Returns a list of buffered log messages associated to a given trace-id. Usually, the trace-id is taken from last_errors()

health.last_errors

Summary: Show the last errors logged

Return type:

- Map[String,String]

Description: Returns a map with the trace-id as key and the most recent error messages as value. Requires that -log-last-errors is enabled (and not turned off).

health.running

Summary: Check if the node is running

Return type:

- Boolean

health.set_log_level

Summary: Change the log level of the process

Arguments:

- level: ch.qos.logback.classic.Level

Description: If the default logback configuration is used, this will change the log level of the process.

health.status

Summary: Get human (and machine) readable status info

Return type:

- com.digitalasset.canton.admin.api.client.data.NodeStatus[S]

health.wait_for_identity

Summary: Wait for the node to have an identity

Description: This is specifically useful for the Domain Manager which needs its identity to be ready for bootstrapping, but for which we can't rely on wait_for_initialized() because

it will be initialized only after being bootstrapped.

`health.wait_for_initialized`

Summary: Wait for the node to be initialized

`health.wait_for_running`

Summary: Wait for the node to be running

28.3.6.3 Database

`db.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`db.migrate`

Summary: Migrates the instance's database if using a database storage

Description: When instances reside on different nodes, their database migration can be run in parallel to save time. Please note that the migration commands must however must be run on each node individually, because remote migration through *participants.remote* is not supported.

`db.repair_migration`

Summary: Only use when advised - repairs the database migration of the instance's database

Arguments:

- `force`: Boolean

Description: In some rare cases, we change already applied database migration files in a new release and the repair command resets the checksums we use to ensure that in general already applied migration files have not been changed. You should only use *db.repair_migration* when advised and otherwise use it at your own risk - in the worst case running it may lead to data corruption when an incompatible database migration (one that should be rejected because the already applied database migration files have changed) is subsequently falsely applied.

28.3.7 Mediator Administration Commands

`clear_cache (Testing)`

Summary: Clear locally cached variables

Description: Some commands cache values on the client side. Use this command to explicitly clear the caches of these values.

`config`

Summary: Returns the mediator configuration

Return type:

- [com.digitalasset.canton.domain.mediator.MediatorNodeConfig](#)

`help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

id

Summary: Yields the mediator id of this mediator. Throws an exception, if the id has not yet been allocated (e.g., the mediator has not yet been initialised).

Return type:

- [com.digitalasset.canton.topology.MediatorId](#)

is_initialized

Summary: Check if the local instance is running and is fully initialized

Return type:

- Boolean

is_running

Summary: Check if the local instance is running

Return type:

- Boolean

start

Summary: Start the instance

stop

Summary: Stop the instance

28.3.7.1 Mediator

mediator.clear_schedule

Summary: Deactivate automatic pruning.

mediator.get_schedule

Summary: Inspect the automatic pruning schedule.

Return type:

- [Option\[com.digitalasset.canton.admin.api.client.data.PruningSchedule\]](#)

Description: The schedule consists of a `cron` expression and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period. Returns `None` if no schedule has been configured via `set_schedule` or if `clear_schedule` has been invoked.

mediator.help

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

mediator.initialize

Summary: Initialize a mediator

Arguments:

- `domainId`: [com.digitalasset.canton.topology.DomainId](#)
- `mediatorId`: [com.digitalasset.canton.topology.MediatorId](#)
- `domainParameters`: [com.digitalasset.canton.admin.api.client.data.StaticDomainParameters](#)
- `sequencerConnection`: [com.digitalasset.canton.sequencing.SequencerConnection](#)

- topologySnapshot: `Option[com.digitalasset.canton.topology.store.StoredTopologyTransactions[com.digitalasset.canton.topology.transaction.TopologyChangeOp.Positive]]`
- signingKeyFingerprint: `Option[com.digitalasset.canton.crypto.Fingerprint]`

Return type:

- `com.digitalasset.canton.crypto.PublicKey`

`mediator.initialize`

Summary: Initialize a mediator

Arguments:

- domainId: `com.digitalasset.canton.topology.DomainId`
- mediatorId: `com.digitalasset.canton.topology.MediatorId`
- domainParameters: `com.digitalasset.canton.admin.api.client.data.StaticDomainParameters`
- sequencerConnections: `com.digitalasset.canton.sequencing.SequencerConnections`
- topologySnapshot: `Option[com.digitalasset.canton.topology.store.StoredTopologyTransactions[com.digitalasset.canton.topology.transaction.TopologyChangeOp.Positive]]`
- signingKeyFingerprint: `Option[com.digitalasset.canton.crypto.Fingerprint]`

Return type:

- `com.digitalasset.canton.crypto.PublicKey`

`mediator.locate_pruning_timestamp`

Summary: Obtain a timestamp at or near the beginning of mediator state

Arguments:

- index: `com.digitalasset.canton.config.RequireTypes.PositiveInt`

Return type:

- `Option[com.digitalasset.canton.data.CantonTimestamp]`

Description: This command provides insight into the current state of mediator pruning when called with the default value of `index 1`. When pruning the mediator manually via `prune_at` and with the intent to prune in batches, specify a value such as 1000 to obtain a pruning timestamp that corresponds to the `end` of the batch.

`mediator.prune`

Summary: Prune the mediator of unnecessary data while keeping data for the default retention period

Description: Removes unnecessary data from the Mediator that is earlier than the default retention period. The default retention period is set in the configuration of the canton node running this command under `parameters.retention-period-defaults.mediator`.

`mediator.prune_at`

Summary: Prune the mediator of unnecessary data up to and including the given timestamp

Arguments:

- timestamp: `com.digitalasset.canton.data.CantonTimestamp`

`mediator.prune_with_retention_period`

Summary: Prune the mediator of unnecessary data while keeping data for the provided retention period

Arguments:

- retentionPeriod: `scala.concurrent.duration.FiniteDuration`

`mediator.set_cron`

Summary: Modify the cron used by automatic pruning.

Arguments:

- `cron`: String

Description: The schedule is specified in cron format and refers to pruning start times in the GMT time zone. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`mediator.set_max_duration`

Summary: Modify the maximum duration used by automatic pruning.

Arguments:

- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `maxDuration` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this modification, pruning is actively running, a best effort is made to pause pruning and restart according to the new schedule. This allows for the case that the new schedule no longer allows pruning at the current time.

`mediator.set_retention`

Summary: Update the pruning retention used by automatic pruning.

Arguments:

- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The `retention` is specified as a positive duration and has at most per-second granularity. This call returns an error if no schedule has been configured via `set_schedule` or if automatic pruning has been disabled via `clear_schedule`. Additionally if at the time of this update, pruning is actively running, a best effort is made to pause pruning and restart with the newly specified retention. This allows for the case that the new retention mandates retaining more data than previously.

`mediator.set_schedule`

Summary: Activate automatic pruning according to the specified schedule.

Arguments:

- `cron`: String
- `maxDuration`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)
- `retention`: [com.digitalasset.canton.config.PositiveDurationSeconds](#)

Description: The schedule is specified in cron format and `max_duration` and `retention` durations. The cron string indicates the points in time at which pruning should begin in the GMT time zone, and the maximum duration indicates how long from the start time pruning is allowed to run as long as pruning has not finished pruning up to the specified retention period.

28.3.7.2 Health

`health.active`

Summary: Check if the node is running and is the active instance (mediator, participant)

Return type:

- Boolean

`health.dump`

Summary: Creates a zip file containing diagnostic information about the canton process running this node

Arguments:

- `outputFile`: `better.files.File`
- `timeout`: `com.digitalasset.canton.config.NonNegativeDuration`
- `chunkSize`: `Option[Int]`

Return type:

- String

`health.has_identity`

Summary: Returns true if the node has an identity

Return type:

- Boolean

`health.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: String

`health.initialized`

Summary: Returns true if node has been initialized.

Return type:

- Boolean

`health.last_error_trace`

Summary: Show all messages logged with the given `traceId` in a recent interval

Arguments:

- `traceId`: String

Return type:

- `Seq[String]`

Description: Returns a list of buffered log messages associated to a given trace-id. Usually, the trace-id is taken from `last_errors()`

`health.last_errors`

Summary: Show the last errors logged

Return type:

- `Map[String,String]`

Description: Returns a map with the trace-id as key and the most recent error messages as value. Requires that `-log-last-errors` is enabled (and not turned off).

`health.running`

Summary: Check if the node is running

Return type:

- Boolean

`health.set_log_level`

Summary: Change the log level of the process

Arguments:

- `level`: `ch.qos.logback.classic.Level`

Description: If the default logback configuration is used, this will change the log level of the process.

`health.status`

Summary: Get human (and machine) readable status info

Return type:

- `com.digitalasset.canton.admin.api.client.data.NodeStatus[S]`

`health.wait_for_identity`

Summary: Wait for the node to have an identity

Description: This is specifically useful for the Domain Manager which needs its identity to be ready for bootstrapping, but for which we can't rely on `wait_for_initialized()` because it will be initialized only after being bootstrapped.

`health.wait_for_initialized`

Summary: Wait for the node to be initialized

`health.wait_for_running`

Summary: Wait for the node to be running

28.3.7.3 Database

`db.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName`: `String`

`db.migrate`

Summary: Migrates the instance's database if using a database storage

Description: When instances reside on different nodes, their database migration can be run in parallel to save time. Please note that the migration commands must however must be run on each node individually, because remote migration through `participants.remote` is not supported.

`db.repair_migration`

Summary: Only use when advised - repairs the database migration of the instance's database

Arguments:

- `force`: `Boolean`

Description: In some rare cases, we change already applied database migration files in a new release and the repair command resets the checksums we use to ensure that in general already applied migration files have not been changed. You should only use `db.repair_migration` when advised and otherwise use it at your own risk - in the worst case running it may lead to data corruption when an incompatible database migration (one that should be rejected because the already applied database migration files have changed) is subsequently falsely applied.

28.3.7.4 Sequencer Connection

`sequencer_connection.get`

Summary: Get Sequencer Connection

Return type:

- `Option[com.digitalasset.canton.sequencing.SequencerConnections]`

Description: Use this command to get the currently configured sequencer connection details for this sequencer client. If this node has not yet been initialized, this will return `None`.

`sequencer_connection.help`

Summary: Help for specific commands (use `help()` or `help(method)` for more information)

Arguments:

- `methodName: String`

`sequencer_connection.modify`

Summary: Modify Default Sequencer Connection

Arguments:

- `modifier: com.digitalasset.canton.sequencing.SequencerConnection => com.digitalasset.canton.sequencing.SequencerConnection`

Description: Modify sequencer connection details for this sequencer client node, by passing a modifier function that operates on the existing default connection.

`sequencer_connection.modify_connections`

Summary: Modify Sequencer Connections

Arguments:

- `modifier: com.digitalasset.canton.sequencing.SequencerConnections => com.digitalasset.canton.sequencing.SequencerConnections`

Description: Modify sequencer connection details for this sequencer client node, by passing a modifier function that operates on the existing connection configuration.

`sequencer_connection.set`

Summary: Set Sequencer Connection

Arguments:

- `connection: com.digitalasset.canton.sequencing.SequencerConnection`

Description: Set new sequencer connection details for this sequencer client node. This will replace any pre-configured connection details. This command will only work after the node has been initialized.

`sequencer_connection.set`

Summary: Set Sequencer Connection

Arguments:

- `connections: com.digitalasset.canton.sequencing.SequencerConnections`

Description: Set new sequencer connection details for this sequencer client node. This will replace any pre-configured connection details. This command will only work after the node has been initialized.

Chapter 29

Monitoring Best Practices

29.1 Introduction

Observability (also known as `monitoring`) lets you determine if the Daml Enterprise solution is healthy or not. If the state is not healthy, observability helps diagnose the root cause. There are three parts to observability: metrics, logs, and traces. These are described in this section.

To avoid becoming overwhelmed by the number of metrics and log messages, follow these steps:

- Read the shortcut to learning what is important, which is described below in the section [Hands-On with the Daml Enterprise - Observability Example](#) as a starting point and inspiration when building your metric monitoring.

- For an overview of how most metrics are exposed, read the section [Golden Signals and Key Metrics Quick Start](#) below. It describes the philosophy behind metric naming and labeling.

The remaining sections provide references to more detailed information.

29.1.1 Hands-On with the Daml Enterprise - Observability Example

The [Daml Enterprise - Observability Example](#) GitHub repository provides a complete reference example for exploring the metrics that Daml Enterprise exposes. You can use it to explore the collection, aggregation, filtering, and visualization of metrics. It is self-contained, with the following components:

- An example Docker compose file to create a run-time for all the components
- Some shell scripts to generate requests to the Daml Enterprise solution
- A Prometheus config file to scrape the metrics data
- A Grafana template file(s) to visualize the metrics in a meaningful way, such as shown below in the example dashboard

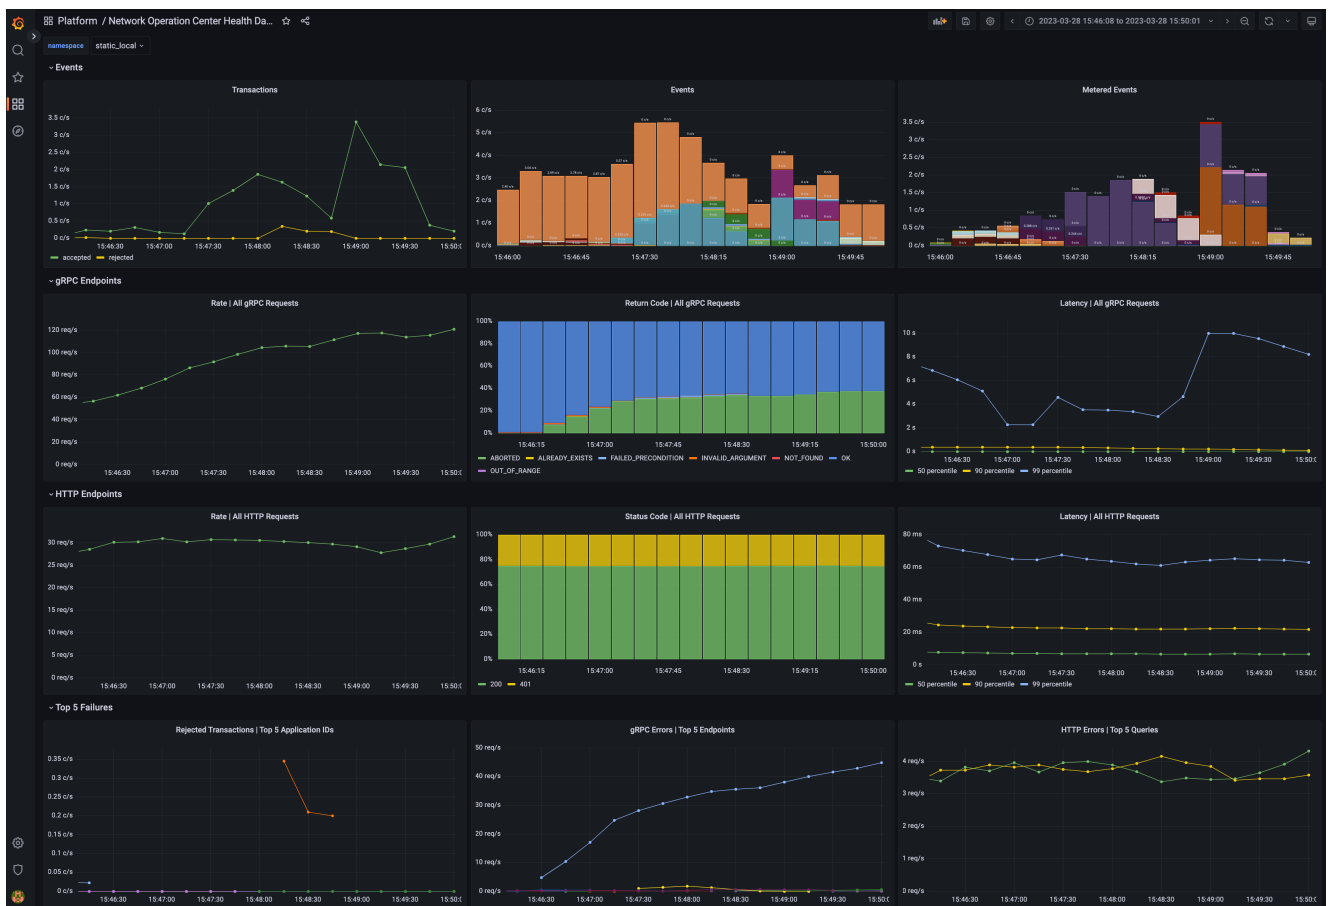

Fig. 1: Dashboard with metrics

29.2 Golden Signals and Key Metrics Quick Start

The best practice for [monitoring a microservices application](#) is an approach known as the [Golden Signals](#), or [the RED method](#). In this approach, metric monitoring determines whether the application is healthy and, if not healthy, which service is the root cause of the issue. The Golden Signals for HTTP and gRPC endpoints are supported for all endpoints. Key metrics specific to Daml Enterprises are also available. These are described below.

The following Golden Signal metrics for each HTTP and gRPC API are available:

- Input request rate, as a counter
- Error rate, as a counter (discussed below)
- Latency (the time to process a request), as a histogram
- Size of the payload, as a counter, following the [Apache HTTP precedent](#)

You can filter or aggregate each metric using its accompanying labels. The instrumentation labels added to each HTTP API metric are as follows:

- `http_verb`: the HTTP verb (for example: GET, POST)
- `http_status`: the status code (for example: 200, 401, 403, 504)
- `host`: the host identifier
- `daml_version`: the Daml release number
- `service`: a string to identify what Daml service or Canton component is running in this process (for example: `participant`, `domain`, `json_api`), as well as `domain` if several Canton components run in a single process
- `path`: the request made to the endpoint (for example: `/v1/create`, `/v1/exercise`)

The gRPC protocol is layered on top of HTTP/2, so certain labels (such as the `daml_version` and `service`) from the above section are included. The labels added by default to each [gRPC API metric](#) are as follows:

- `canton_version`: the [Canton protocol version](#)
- `grpc_code`: the human-readable status code for gRPC (for example: OK, CANCELLED, DEADLINE_EXCEEDED)
- The type of the client/server gRPC [request](#), under the labels `grpc_client_type` and `grpc_server_type`
- The protobuf package and service names, under the labels `grpc_service_name` and `grpc_method_name`

The following other key metrics are monitored:

A binary gauge indicates whether the node is [healthy or not healthy](#). This can also be used to infer which node is passive in a highly available configuration because it will show as not being healthy, while the active node is always healthy.

A binary gauge signals whether a node is active or passive, for identifying which node is the active node.

A binary gauge [detects when pruning is occurring](#).

Each participant node measures the count of the inflight (dirty) requests so the user can see if `maxDirtyRequests` limit is close to being hit. The metrics are: `canton_dirty_requests` and `canton_max_dirty_requests`.

Each participant node records the distribution of events (updates) received by the participant and allows drill-down by event type (package upload, party creation, or transaction), status (success or failure), participant ID, and application ID (if available). The counter is called `daml_indexer_events_total`.

The ledger event requests are totaled in a counter called `daml_indexer_metered_events_total`.

[JVM garbage collection metrics](#) are collected.

This list is not exhaustive. It highlights the most important metrics.

29.3 Set Up Metrics Scraping

29.3.1 Enable the Prometheus Reporter

[Prometheus](#) is recommended for metrics reporting. Other reporters (jmx, graphite, and csv) are supported, but they are deprecated. Any such reporter should be migrated to Prometheus.

Prometheus can be enabled using:

```
canton.monitoring.metrics.reporters = [{
  type = prometheus
  address = "localhost" // default
  port = 9000 // default
}]
```

29.3.2 Prometheus-Only Metrics

Some metrics are available only when using the Prometheus reporter. These metrics include common gRPC and HTTP metrics (which help you to measure [the four golden signals](#)), and JVM GC and memory usage metrics (if enabled). The metrics are documented in detail below.

Any metric marked with * is available only when using the Prometheus reporter.

29.3.3 Deprecated Reporters

JMX-based reporting (for testing purposes only) can be enabled using:

```
canton.monitoring.metrics.reporters = [{ type = jmx }]
```

Additionally, metrics can be written to a file:

```
canton.monitoring.metrics.reporters = [{
  type = jmx
}, {
  type = csv
  directory = "metrics"
  interval = 5s // default
  filters = [{
    contains = "canton"
  }]
}]
```

or reported via Graphite (to Grafana) using:

```
canton.monitoring.metrics.reporters = [{  
  type = graphite  
  address = "localhost" // default  
  port = 2003  
  prefix.type = hostname // default  
  interval = 30s // default  
  filters = [{  
    contains = "canton"  
  }]  
}]
```

When using the `graphite` or the `csv` reporter, Canton periodically evaluates all metrics matching the given filters. Filter for only those metrics that are relevant to you.

In addition to Canton metrics, the process can also report Daml metrics (of the Ledger API server). Optionally, JVM metrics can be included using:

```
canton.monitoring.metrics.report-jvm-metrics = yes // default no
```

29.4 Metrics

The following sections contain the common metrics exposed for Daml services supporting a Prometheus metrics reporter.

For the metric types referenced below, see the [relevant Prometheus documentation](#).

29.4.1 Participant Metrics

29.4.1.1 `canton.<domain>.conflict-detection.sequencer-counter-queue`

Summary: Size of conflict detection sequencer counter queue

Description: The task scheduler will work off tasks according to the timestamp order, scheduling the tasks whenever a new timestamp has been observed. This metric exposes the number of un-processed sequencer messages that will trigger a timestamp advancement.

Type: Counter

Qualification: Debug

29.4.1.2 `canton.<domain>.conflict-detection.task-queue`

Summary: Size of conflict detection task queue

Description: This metric measures the size of the queue for conflict detection between concurrent transactions. A huge number does not necessarily indicate a bottleneck; it could also mean that a huge number of tasks have not yet arrived at their execution time.

Type: Gauge

Qualification: Debug

29.4.1.3 `canton.<domain>.protocol-messages.confirmation-request-creation`

Summary: Time to create a confirmation request

Description: The time that the transaction protocol processor needs to create a confirmation request.

Type: Timer

Qualification: Debug

29.4.1.4 `canton.<domain>.protocol-messages.confirmation-request-size`

Summary: Confirmation request size

Description: Records the histogram of the sizes of (transaction) confirmation requests.

Type: Histogram

Qualification: Debug

29.4.1.5 `canton.<domain>.protocol-messages.transaction-message-receipt`

Summary: Time to parse a transaction message

Description: The time that the transaction protocol processor needs to parse and decrypt an incoming confirmation request.

Type: Timer

Qualification: Debug

29.4.1.6 `canton.<domain>.request-tracker.sequencer-counter-queue`

Summary: Size of record order publisher sequencer counter queue

Description: Same as for conflict-detection, but measuring the sequencer counter queues for the publishing to the ledger api server according to record time.

Type: Counter

Qualification: Debug

29.4.1.7 `canton.<domain>.request-tracker.task-queue`

Summary: Size of record order publisher task queue

Description: The task scheduler will schedule tasks to run at a given timestamp. This metric exposes the number of tasks that are waiting in the task queue for the right time to pass.

Type: Gauge

Qualification: Debug

29.4.1.8 `canton.<domain>.sequencer-client.application-handle`

Summary: Timer monitoring time and rate of sequentially handling the event application logic

Description: All events are received sequentially. This handler records the the rate and time it takes the application (participant or domain) to handle the events.

Type: Timer

Qualification: Debug

29.4.1.9 `canton.<domain>.sequencer-client.delay`

Summary: The delay on the event processing

Description: Every message received from the sequencer carries a timestamp that was assigned by the sequencer when it sequenced the message. This timestamp is called the sequencing timestamp. The component receiving the message on the participant, mediator or topology manager side, is the sequencer client. Upon receiving the message, the sequencer client compares the time difference between the sequencing time and the computers local clock and exposes this difference as the given metric. The difference will include the clock-skew and the processing latency between assigning the timestamp on the sequencer and receiving the message by the recipient. If the difference is large compared to the usual latencies and if clock skew can be ruled out, then it means that the node is still trying to catch up with events that were sequenced by the sequencer a while ago. This can happen after having been offline for a while or if the node is too slow to keep up with the messaging load.

Type: Gauge

Qualification: Debug

29.4.1.10 `canton.<domain>.sequencer-client.event-handle`

Summary: Timer monitoring time and rate of entire event handling

Description: Most event handling cost should come from the application-handle. This timer measures the full time (which should just be marginally more than the application handle).

Type: Timer

Qualification: Debug

29.4.1.11 `canton.<domain>.sequencer-client.handler.actual-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks how many such batches are processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Indicators that the configured upper bound may be too low: This metric constantly is closed to the configured maximum, which is exposed via 'max-in-flight-event-batches', while the system's resources are under-utilized. Indicators that the configured upper bound may be too high: Out-of-memory errors crashing the JVM or frequent garbage collection cycles that slow down processing. The metric tracks how many of these batches have been sent to the application handler but have not yet been fully processed. This metric can help identify potential bottlenecks or issues with the application's processing of events and provide insights into the overall workload of the system.

Type: Counter

Qualification: Saturation

29.4.1.12 `canton.<domain>.sequencer-client.handler.max-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks the upper bound of such batches being processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Configured by 'maximum-in-flight-event-batches' parameter in the sequencer-client config. The metric shows the configured upper limit on how many batches the application handler may process concurrently. The metric 'actual-in-flight-event-batches' tracks the actual number of currently processed batches.

Type: Gauge

Qualification: Saturation

29.4.1.13 `canton.<domain>.sequencer-client.submissions.dropped`

Summary: Count of send requests that did not cause an event to be sequenced

Description: Counter of send requests we did not witness a corresponding event to be sequenced by the supplied max-sequencing-time. There could be many reasons for this happening: the request may have been lost before reaching the sequencer, the sequencer may be at capacity and the the max-sequencing-time was exceeded by the time the request was processed, or the supplied max-sequencing-time may just be too small for the sequencer to be able to sequence the request.

Type: Counter

Qualification: Debug

29.4.1.14 `canton.<domain>.sequencer-client.submissions.in-flight`

Summary: Number of sequencer send requests we have that are waiting for an outcome or timeout

Description: Incremented on every successful send to the sequencer. Decrementd when the event or an error is sequenced, or when the max-sequencing-time has elapsed.

Type: Counter

Qualification: Debug

29.4.1.15 `canton.<domain>.sequencer-client.submissions.overloaded`

Summary: Count of send requests which receive an overloaded response

Description: Counter that is incremented if a send request receives an overloaded response from the sequencer.

Type: Counter

Qualification: Debug

29.4.1.16 `canton.<domain>.sequencer-client.submissions.sends`

Summary: Rate and timings of send requests to the sequencer

Description: Provides a rate and time of how long it takes for send requests to be accepted by the sequencer. Note that this is just for the request to be made and not for the requested event to actually be sequenced.

Type: Timer

Qualification: Debug

29.4.1.17 `canton.<domain>.sequencer-client.submissions.sequencing`

Summary: Rate and timings of sequencing requests

Description: This timer is started when a submission is made to the sequencer and then completed when a corresponding event is witnessed from the sequencer, so will encompass the entire duration for the sequencer to sequence the request. If the request does not result in an event no timing will be recorded.

Type: Timer

Qualification: Debug

29.4.1.18 `canton.<domain>.traffic-control.event-above-traffic-limit`

Summary: Event was not delivered because of traffic limit exceeded

Description: An event was not delivered because of insufficient traffic credit.

Type: Meter

Qualification: Traffic

29.4.1.19 `canton.<domain>.traffic-control.event-delivered`

Summary: Event was delivered

Description: An event was not delivered.

Type: Meter

Qualification: Traffic

29.4.1.20 `canton.<domain>.traffic-control.extra-traffic-credit-available`

Summary: Current amount of extra traffic remaining

Description: Gets updated with every event received.

Type: Gauge

Qualification: Traffic

29.4.1.21 `canton.<domain>.traffic-control.traffic-state-topology-transaction`

Summary: Records a new top up on the participant

Description: Records top up events and the new extra traffic limit associated.

Type: Gauge

Qualification: Traffic

29.4.1.22 `canton.commitments.catchup-mode-enabled`

Summary: Times the catch up mode has been activated.

Description: Participant nodes compute bilateral commitments at regular intervals. This metric exposes how often catch-up mode has been activated. Catch-up mode is triggered according to catch-up config and happens if the participant lags behind on computation.

Type: Meter

Qualification: Debug

29.4.1.23 `canton.commitments.compute`

Summary: Time spent on commitment computations.

Description: Participant nodes compute bilateral commitments at regular intervals. This metric exposes the time spent on each computation. If the time to compute the metrics starts to exceed the commitment intervals, this likely indicates a problem.

Type: Timer

Qualification: Debug

29.4.1.24 `canton.commitments.sequencing-time`

Summary: Time spent in microseconds between commitment and sequencing.

Description: Participant nodes compute bilateral commitments at regular intervals. After a commitment has been computed it is sent for sequencing. This measures the time between the end of a commitment interval and when the commitment has been sequenced. A high value indicates that the participant is lagging behind in processing messages and computing commitments or the sequencer is slow in sequencing the commitment messages.

Type: Gauge

Qualification: Debug

29.4.1.25 `canton.db-storage.<service>.executor.exectime`

Summary: Execution time metric for database tasks

Description: The time a task is running on the database is measured using this metric.

Type: Timer

Qualification: Debug

Instances: locks, write, general

29.4.1.26 `canton.db-storage.<service>.executor.load`

Summary: Load of database pool

Description: Database queries run as tasks on an async executor. This metric shows the current number of queries running in parallel divided by the number database connections for this database connection pool.

Type: Gauge

Qualification: Debug

Instances: locks, write, general

29.4.1.27 `canton.db-storage.<service>.executor.queued`

Summary: Number of database access tasks waiting in queue

Description: Database access tasks get scheduled in this queue and get executed using one of the existing asynchronous sessions. A large queue indicates that the database connection is not able to deal with the large number of requests. Note that the queue has a maximum size. Tasks that do not fit into the queue will be retried, but won't show up in this metric.

Type: Counter

Qualification: Debug

Instances: locks, write, general

29.4.1.28 `canton.db-storage.<service>.executor.running`

Summary: Number of database access tasks currently running

Description: Database access tasks run on an async executor. This metric shows the current number of tasks running in parallel.

Type: Gauge

Qualification: Debug

Instances: locks, write, general

29.4.1.29 `canton.db-storage.<service>.executor.waittime`

Summary: Scheduling time metric for database tasks

Description: Every database query is scheduled using an asynchronous executor with a queue. The time a task is waiting in this queue is monitored using this metric.

Type: Timer

Qualification: Debug

Instances: locks, write, general

29.4.1.30 `canton.db-storage.<storage>`

Summary: Timer monitoring duration and rate of accessing the given storage

Description: Covers both read from and writes to the storage.

Type: Timer

Qualification: Debug

29.4.1.31 `canton.db-storage.<storage>.load`

Summary: The load on the given storage

Description: The load is a factor between 0 and 1 describing how much of an existing interval has been spent reading from or writing to the storage.

Type: Gauge

Qualification: Debug

29.4.1.32 `canton.db-storage.alerts.multi-domain-event-log`

Summary: Number of failed writes to the multi-domain event log

Description: Failed writes to the multi domain event log indicate an issue requiring user intervention. In the case of domain event logs, the corresponding domain no longer emits any subsequent events until domain recovery is initiated (e.g. by disconnecting and reconnecting the participant from the domain). In the case of the participant event log, an operation might need to be reissued. If this counter is larger than zero, check the canton log for errors for details.

Type: Counter

Qualification: Debug

29.4.1.33 `canton.db-storage.alerts.single-dimension-event-log`

Summary: Number of failed writes to the event log

Description: Failed writes to the single dimension event log indicate an issue requiring user intervention. In the case of domain event logs, the corresponding domain no longer emits any subsequent events until domain recovery is initiated (e.g. by disconnecting and reconnecting the participant from the domain). In the case of the participant event log, an operation might need to be reissued. If this counter is larger than zero, check the canton log for errors for details.

Type: Counter

Qualification: Debug

29.4.1.34 `canton.dirty_requests*`

Summary: Number of requests being validated.

Description: Number of requests that are currently being validated. This also covers requests submitted by other participants.

Type: Gauge

Qualification: Debug

Labels:

- **participant:** The id of the participant for which the value applies.

29.4.1.35 `canton.max_dirty_requests*`

Summary: Configured maximum number of requests currently being validated.

Description: Configuration for the maximum number of requests that are currently being validated. This also covers requests submitted by other participants. A negative value means no configuration value was provided and no limit is enforced.

Type: Gauge

Qualification: Debug

Labels:

- **participant:** The id of the participant for which the value applies.

29.4.1.36 `canton.prune`

Summary: Duration of prune operations.

Description: This timer exposes the duration of pruning requests from the Canton portion of the ledger.

Type: Timer

Qualification: Debug

29.4.1.37 `canton.prune.max-event-age`

Summary: Age of oldest unpruned event.

Description: This gauge exposes the age of the oldest, unpruned event in hours as a way to quantify the pruning backlog.

Type: Gauge

Qualification: Debug

29.4.1.38 `canton.updates-published`

Summary: Number of updates published through the read service to the indexer

Description: When an update is published through the read service, it has already been committed to the ledger. The indexer will subsequently store the update in a form that allows for querying the ledger efficiently.

Type: Meter

Qualification: Debug

29.4.1.39 `daml.cache.evicted_weight*`

Summary: The sum of weights of cache entries evicted.

Description: The total weight of the entries evicted from the cache.

Type: Counter

Qualification: Debug

Labels:

- **name:** The cache for which the metrics are registered.

29.4.1.40 `daml.cache.evictions*`

Summary: The number of the evicted cache entries.

Description: When an entry is evicted from the cache, the counter is incremented.

Type: Counter

Qualification: Debug

Labels:

- **name:** The cache for which the metrics are registered.

29.4.1.41 `daml.cache.hits*`

Summary: The number of cache hits.

Description: When a cache lookup encounters an existing cache entry, the counter is incremented.

Type: Counter

Qualification: Debug

Labels:

- **name:** The cache for which the metrics are registered.

29.4.1.42 `daml.cache.misses*`

Summary: The number of cache misses.

Description: When a cache lookup first encounters a missing cache entry, the counter is incremented.

Type: Counter

Qualification: Debug

Labels:

- **name:** The cache for which the metrics are registered.

29.4.1.43 `daml.commands.delayed_submissions`

Summary: The number of the delayed Daml commands.

Description: The number of Daml commands that have been delayed internally because they have been evaluated to require the ledger time further in the future than the expected latency.

Type: Meter

Qualification: Debug

29.4.1.44 `daml.commands.failed_command_interpretations`

Summary: The number of Daml commands that failed in interpretation.

Description: The number of Daml commands that have been rejected by the interpreter (e.g. badly authorized action).

Type: Meter

Qualification: Debug

29.4.1.45 `daml.commands.max_in_flight_capacity`

Summary: The maximum number of Daml commands that can await completion.

Description: The maximum number of Daml commands that can await completion in the Command Service.

Type: Counter

Qualification: Debug

29.4.1.46 `daml.commands.max_in_flight_length`

Summary: The number of the Daml commands awaiting completion.

Description: The number of the currently Daml commands awaiting completion in the Command Service.

Type: Counter

Qualification: Debug

29.4.1.47 `daml.commands.reassignment_validation`

Summary: The time to validate a reassignment command.

Description: The time to validate a submitted Daml command before is fed to the interpreter.

Type: Timer

Qualification: Debug

29.4.1.48 `daml.commands.submissions`

Summary: The time to fully process a Daml command.

Description: The time to validate and interpret a command before it is handed over to the synchronization services to be finalized (either committed or rejected).

Type: Timer

Qualification: Latency

29.4.1.49 `daml.commands.submissions_running`

Summary: The number of the Daml commands that are currently being handled by the ledger api server.

Description: The number of the Daml commands that are currently being handled by the ledger api server (including validation, interpretation, and handing the transaction over to the synchronization services).

Type: Counter

Qualification: Debug

29.4.1.50 `daml.commands.valid_submissions`

Summary: The total number of the valid Daml commands.

Description: The total number of the Daml commands that have passed validation and were sent to interpretation in this ledger api server process.

Type: Meter

Qualification: Debug

29.4.1.51 `daml.commands.validation`

Summary: The time to validate a Daml command.

Description: The time to validate a submitted Daml command before is fed to the interpreter.

Type: Timer

Qualification: Debug

29.4.1.52 `daml.db.commit.duration.seconds*`

Summary: The time needed to perform the SQL query commit.

Description: This metric measures the time it takes to commit an SQL transaction relating to the `<operation>`. It roughly corresponds to calling `commit()` on a DB connection.

Type: Timer

Qualification: Debug

Labels:

- **name:** The operation/pool for which the metric is registered.

29.4.1.53 `daml.db.compression.duration.seconds*`

Summary: The time needed to decompress the SQL query result.

Description: Some index database queries that target contracts involve a decompression step. For such queries this metric represents the time it takes to decompress contract arguments retrieved from the database.

Type: Timer

Qualification: Debug

Labels:

- **name:** The operation/pool for which the metric is registered.

29.4.1.54 `daml.db.exec.duration.seconds*`

Summary: The time needed to run the SQL query and read the result.

Description: This metric encompasses the time measured by `query` and `commit` metrics. Additionally it includes the time needed to obtain the DB connection, optionally roll it back and close the connection at the end.

Type: Timer

Qualification: Debug

Labels:

- **name:** The operation/pool for which the metric is registered.

29.4.1.55 `daml.db.query.duration.seconds*`

Summary: The time needed to run the SQL query.

Description: This metric measures the time it takes to execute a block of code (on a dedicated executor) related to the <operation> that can issue multiple SQL statements such that all run in a single DB transaction (either committed or aborted).

Type: Timer

Qualification: Debug

Labels:

- **name:** The operation/pool for which the metric is registered.

29.4.1.56 `daml.db.translation.duration.seconds*`

Summary: The time needed to turn serialized Daml-LF values into in-memory objects.

Description: Some index database queries that target contracts and transactions involve a Daml-LF translation step. For such queries this metric stands for the time it takes to turn the serialized Daml-LF values into in-memory representation.

Type: Timer

Qualification: Debug

Labels:

- **name:** The operation/pool for which the metric is registered.

29.4.1.57 `daml.db.wait.duration.seconds*`

Summary: The time needed to acquire a connection to the database.

Description: SQL statements are run in a dedicated executor. This metric measures the time it takes between creating the SQL statement corresponding to the <operation> and the point when it starts running on the dedicated executor.

Type: Timer

Qualification: Debug

Labels:

- **name:** The operation/pool for which the metric is registered.

29.4.1.58 `daml.execution.cache.contract_state.register_update`

Summary: The time spent to update the cache.

Description: The total time spent in sequential update steps of the contract state caches updating logic. This metric is created with debugging purposes in mind.

Type: Timer

Qualification: Debug

29.4.1.59 `daml.execution.cache.key_state.register_update`

Summary: The time spent to update the cache.

Description: The total time spent in sequential update steps of the contract state caches updating logic. This metric is created with debugging purposes in mind.

Type: Timer

Qualification: Debug

29.4.1.60 `daml.execution.cache.read_through_not_found`

Summary: The number of cache read-throughs resulting in not found contracts.

Description: On cache misses, a read-through query is performed against the Index database. When the contract is not found (as result of this query), this counter is incremented.

Type: Counter

Qualification: Debug

29.4.1.61 `daml.execution.cache.resolve_divulgence_lookup`

Summary: The number of lookups trying to resolve divulged contracts on active contracts cache hits.

Description: Divulged contracts are not cached in the contract state caches. On active contract cache hits, where stakeholders are not within the submission readers, a contract activeness lookup is performed against the Index database. On such lookups, this counter is incremented.

Type: Counter

Qualification: Debug

29.4.1.62 `daml.execution.cache.resolve_full_lookup`

Summary: The number of lookups trying to resolve divulged contracts on archived contracts cache hits.

Description: Divulged contracts are not cached in the contract state caches. On archived contract cache hits, where stakeholders are not within the submission readers, a full contract activeness lookup (including fetching contract arguments) is performed against the Index database. On such lookups, this counter is incremented.

Type: Counter

Qualification: Debug

29.4.1.63 `daml.execution.engine`

Summary: The time spent executing a Daml command.

Description: The time spent by the Daml engine executing a Daml command (excluding fetching data).

Type: Timer

Qualification: Debug

29.4.1.64 `daml.execution.engine_running`

Summary: The number of Daml commands currently being executed.

Description: The number of the commands that are currently being executed by the Daml engine (excluding fetching data).

Type: Counter

Qualification: Debug

29.4.1.65 `daml.execution.get_if_package`

Summary: The time to fetch individual Daml code packages during interpretation.

Description: The interpretation of a command in the ledger api server might require fetching multiple Daml packages. This metric exposes the time needed to fetch the packages that are necessary for interpretation.

Type: Timer

Qualification: Debug

29.4.1.66 `daml.execution.lookup_active_contract`

Summary: The time to lookup individual active contracts during interpretation.

Description: The interpretation of a command in the ledger api server might require fetching multiple active contracts. This metric exposes the time to lookup individual active contracts.

Type: Timer

Qualification: Debug

29.4.1.67 `daml.execution.lookup_active_contract_count_per_execution`

Summary: The number of the active contracts looked up per Daml command.

Description: The interpretation of a command in the ledger api server might require fetching multiple active contracts. This metric exposes the number of active contracts that must be looked up to process a Daml command.

Type: Histogram

Qualification: Debug

29.4.1.68 `daml.execution.lookup_active_contract_per_execution`

Summary: The compound time to lookup all active contracts in a single Daml command.

Description: The interpretation of a command in the ledger api server might require fetching multiple active contracts. This metric exposes the compound time to lookup all the active contracts in a single Daml command.

Type: Timer

Qualification: Debug

29.4.1.69 `daml.execution.lookup_contract_key`

Summary: The time to lookup individual contract keys during interpretation.

Description: The interpretation of a command in the ledger api server might require fetching multiple contract keys. This metric exposes the time needed to lookup individual contract keys.

Type: Timer

Qualification: Debug

29.4.1.70 `daml.execution.lookup_contract_key_count_per_execution`

Summary: The number of contract keys looked up per Daml command.

Description: The interpretation of a command in the ledger api server might require fetching multiple contract keys. This metric exposes the number of contract keys that must be looked up to process a Daml command.

Type: Histogram

Qualification: Debug

29.4.1.71 `daml.execution.lookup_contract_key_per_execution`

Summary: The compound time to lookup all contract keys in a single Daml command.

Description: The interpretation of a command in the ledger api server might require fetching multiple contract keys. This metric exposes the compound time needed to lookup all the contract keys in a single Daml command.

Type: Timer

Qualification: Debug

29.4.1.72 `daml.execution.retry`

Summary: The number of the interpretation retries.

Description: The total number of interpretation retries attempted due to mismatching ledger effective time in this ledger api server process.

Type: Meter

Qualification: Debug

29.4.1.73 `daml.execution.total`

Summary: The overall time spent interpreting a Daml command.

Description: The time spent interpreting a Daml command in the ledger api server (includes executing Daml and fetching data).

Type: Timer

Qualification: Debug

29.4.1.74 `daml.execution.total_running`

Summary: The number of Daml commands currently being interpreted.

Description: The number of the commands that are currently being interpreted (includes executing Daml code and fetching data).

Type: Counter

Qualification: Debug

29.4.1.75 `daml.executor.runtime.completed*`

Summary: The number of tasks completed in an instrumented executor.

Description: The number of tasks completed by this executor

Type: Meter

Qualification: Debug

Labels:

- **name:** The name of the executor service.
- **type:** The type of the executor service. Can be *fork_join* or *thread_pool*.

29.4.1.76 `daml.executor.runtime.duration*`

Summary: The time a task runs in an instrumented executor.

Description: A task is considered running only after it has started execution.

Type: Timer

Qualification: Debug

Labels:

- **name:** The name of the executor service.
- **type:** The type of the executor service. Can be *fork_join* or *thread_pool*.

29.4.1.77 `daml.executor.runtime.idle*`

Summary: The time that a task is idle in an instrumented executor.

Description: A task is considered idle if it was submitted to the executor but it has not started execution yet.

Type: Timer

Qualification: Debug

Labels:

- **name:** The name of the executor service.
- **type:** The type of the executor service. Can be *fork_join* or *thread_pool*.

29.4.1.78 `daml.executor.runtime.running*`

Summary: The number of tasks running in an instrumented executor.

Description: The number of currently running tasks.

Type: Counter

Qualification: Debug

Labels:

- **name:** The name of the executor service.
- **type:** The type of the executor service. Can be *fork_join* or *thread_pool*.

29.4.1.79 `daml.executor.runtime.submitted*`

Summary: The number of tasks submitted to an instrumented executor.

Description: Number of tasks that were submitted to the executor.

Type: Meter

Qualification: Debug

Labels:

- **name:** The name of the executor service.
- **type:** The type of the executor service: *fork_join* or *thread_pool*.

29.4.1.80 `daml.index.active_contracts_buffer_size`

Summary: The buffer size for active contracts requests.

Description: An Pekko stream buffer is added at the end of all streaming queries, allowing to absorb temporary downstream backpressure (e.g. when the client is slower than upstream delivery throughput). This metric gauges the size of the buffer for queries requesting active contracts that transactions satisfying a given predicate.

Type: Counter

Qualification: Saturation

29.4.1.81 `daml.index.completions_buffer_size`

Summary: The buffer size for completions requests.

Description: An Pekko stream buffer is added at the end of all streaming queries, allowing to absorb temporary downstream backpressure (e.g. when the client is slower than upstream delivery throughput). This metric gauges the size of the buffer for queries requesting the completed commands in a specific period of time.

Type: Counter

Qualification: Saturation

29.4.1.82 `daml.index.db.active_contract_keys_lookup.batch.active_contract_lookup.batch_size`

Summary: The batch sizes in the lookup batch-loading Contract Service.

Description: The number of lookups contained in a batch, used in the batch-loading Contract Service.

Type: Histogram

Qualification: Debug

29.4.1.83 `daml.index.db.active_contract_keys_lookup.batch.active_contract_lookup.buffer_capacity`

Summary: The capacity of the lookup queue.

Description: The maximum number of elements that can be kept in the queue of lookups in the batch-loading queue of the Contract Service.

Type: Counter

Qualification: Debug

29.4.1.84 `daml.index.db.active_contract_keys_lookup.batch.active_contract_lookup.buffer_delay.duration.seconds`

Summary: The queuing delay for the lookup queue.

Description: The queuing delay for the pending lookups in the batch-loading queue of the Contract Service.

Type: Timer

Qualification: Debug

29.4.1.85 `daml.index.db.active_contract_keys_lookup.batch.active_contract_lookup.buffer_length`

Summary: The number of the currently pending active contract lookups.

Description: The number of the currently pending active contract lookups in the batch-loading queue of the Contract Service.

Type: Counter

Qualification: Debug

29.4.1.86 `daml.index.db.active_contract_lookup.batch.active_contract_lookup.batch_size`

Summary: The batch sizes in the lookup batch-loading Contract Service.

Description: The number of lookups contained in a batch, used in the batch-loading Contract Service.

Type: Histogram

Qualification: Debug

29.4.1.87 `daml.index.db.active_contract_lookup.batch.active_contract_lookup.buffer_capacity`

Summary: The capacity of the lookup queue.

Description: The maximum number of elements that can be kept in the queue of lookups in the batch-loading queue of the Contract Service.

Type: Counter

Qualification: Debug

29.4.1.88 `daml.index.db.active_contract_lookup.batch.active_contract_lookup.buffer_delay.duration.seconds`

Summary: The queuing delay for the lookup queue.

Description: The queuing delay for the pending lookups in the batch-loading queue of the Contract Service.

Type: Timer

Qualification: Debug

29.4.1.89 `daml.index.db.active_contract_lookup.batch.active_contract_lookup.buffer_length`

Summary: The number of the currently pending active contract lookups.

Description: The number of the currently pending active contract lookups in the batch-loading queue of the Contract Service.

Type: Counter

Qualification: Debug

29.4.1.90 `daml.index.db.compression.create_argument_compressed`

Summary: The size of the compressed arguments of a create event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of compressed arguments of a create event.

Type: Histogram

Qualification: Debug

29.4.1.91 `daml.index.db.compression.create_argument_uncompressed`

Summary: The size of the decompressed argument of a create event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of decompressed arguments of a create event.

Type: Histogram

Qualification: Debug

29.4.1.92 `daml.index.db.compression.create_key_value_compressed`

Summary: The size of the compressed key value of a create event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of compressed key value of a create event.

Type: Histogram

Qualification: Debug

29.4.1.93 `daml.index.db.compression.create_key_value_uncompressed`

Summary: The size of the decompressed key value of a create event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of decompressed key value of a create event.

Type: Histogram

Qualification: Debug

29.4.1.94 `daml.index.db.compression.exercise_argument_compressed`

Summary: The size of the compressed argument of an exercise event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of compressed arguments of an exercise event.

Type: Histogram

Qualification: Debug

29.4.1.95 `daml.index.db.compression.exercise_argument_uncompressed`

Summary: The size of the decompressed argument of an exercise event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of decompressed arguments of an exercise event.

Type: Histogram

Qualification: Debug

29.4.1.96 `daml.index.db.compression.exercise_result_compressed`

Summary: The size of the compressed result of an exercise event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of compressed result of an exercise event.

Type: Histogram

Qualification: Debug

29.4.1.97 `daml.index.db.compression.exercise_result_uncompressed`

Summary: The size of the decompressed result of an exercise event.

Description: Event information can be compressed by the indexer before storing it in the database. This metric collects statistics about the size of compressed result of an exercise event.

Type: Histogram

Qualification: Debug

29.4.1.98 `daml.index.db.flat_transactions_stream.translation`

Summary: The time needed to turn serialized Daml-LF values into in-memory objects.

Description: Some index database queries that target contracts and transactions involve a Daml-LF translation step. For such queries this metric stands for the time it takes to turn the serialized Daml-LF values into in-memory representation.

Type: Timer

Qualification: Debug

29.4.1.99 `daml.index.db.lookup_active_contract`

Summary: The time spent fetching a contract using its id.

Description: This metric exposes the time spent fetching a contract using its id from the index db. It is then used by the Daml interpreter when evaluating a command into a transaction.

Type: Timer

Qualification: Debug

29.4.1.100 `daml.index.db.lookup_key`

Summary: The time spent looking up a contract using its key.

Description: This metric exposes the time spent looking up a contract using its key in the index db. It is then used by the Daml interpreter when evaluating a command into a transaction.

Type: Timer

Qualification: Debug

29.4.1.101 `daml.index.db.reassignment_stream.translation`

Summary: The time needed to turn serialized Daml-LF values into in-memory objects.

Description: Some index database queries that target contracts and transactions involve a Daml-LF translation step. For such queries this metric stands for the time it takes to turn the serialized Daml-LF values into in-memory representation.

Type: Timer

Qualification: Debug

29.4.1.102 `daml.index.db.translation.get_lf_package`

Summary: The time needed to deserialize and decode a Daml-LF archive.

Description: A Daml archive before it can be used in the interpretation needs to be deserialized and decoded, in other words converted into the in-memory representation. This metric represents time necessary to do that.

Type: Timer

Qualification: Debug

29.4.1.103 `daml.index.db.tree_transactions_stream.translation`

Summary: The time needed to turn serialized Daml-LF values into in-memory objects.

Description: Some index database queries that target contracts and transactions involve a Daml-LF translation step. For such queries this metric stands for the time it takes to turn the serialized Daml-LF values into in-memory representation.

Type: Timer

Qualification: Debug

29.4.1.104 `daml.index.flat_transactions_buffer_size`

Summary: The buffer size for flat transactions requests.

Description: An Pekko stream buffer is added at the end of all streaming queries, allowing to absorb temporary downstream backpressure (e.g. when the client is slower than upstream delivery throughput). This metric gauges the size of the buffer for queries requesting flat transactions in a specific period of time that satisfy a given predicate.

Type: Counter

Qualification: Saturation

29.4.1.105 `daml.index.ledger_end_sequential_id`

Summary: The sequential id of the current ledger end kept in memory.

Description: The ledger end's sequential id is a monotonically increasing integer value representing the sequential id ascribed to the most recent ledger event ingested by the index db. Please note, that only a subset of all ledger events are ingested and given a sequential id. These are: creates, consuming exercises, non-consuming exercises and divulgence events. This value can be treated as a counter of all such events visible to a given participant. This metric exposes the latest ledger end's sequential id registered in the in-memory data set.

Type: Gauge

Qualification: Debug

29.4.1.106 `daml.index.if_value.compute_interface_view`

Summary: The time to compute an interface view while serving transaction streams.

Description: Transaction API allows clients to request events by interface-id. When an event matches the interface - an interface view is computed, which adds to the latency. This metric represents the time for each such computation.

Type: Timer

Qualification: Debug

29.4.1.107 `daml.index.package_metadata.decode_archive`

Summary: The time to decode a package archive to extract metadata information.

Description: This metric represents the time spent scanning each uploaded package for new interfaces and corresponding templates.

Type: Timer

Qualification: Debug

29.4.1.108 `daml.index.package_metadata.view_init`

Summary: The time to initialize package metadata view.

Description: As the mapping between interfaces and templates is not persistent - it is computed for each Indexer restart by loading all packages which were ever uploaded and scanning them to extract metadata information.

Type: Timer

Qualification: Debug

29.4.1.109 `daml.index.transaction_trees_buffer_size`

Summary: The buffer size for transaction trees requests.

Description: An Pekko stream buffer is added at the end of all streaming queries, allowing to absorb temporary downstream backpressure (e.g. when the client is slower than upstream delivery throughput). This metric gauges the size of the buffer for queries requesting transaction trees.

Type: Counter

Qualification: Saturation

29.4.1.110 `daml.indexer.current_record_time_lag`

Summary: The lag between the record time of a transaction and the wall-clock time registered at the ingestion phase to the index db (in milliseconds).

Description: Depending on the systemic clock skew between different machines, this value can be negative.

Type: Gauge

Qualification: Debug

29.4.1.111 `daml.indexer.events*`

Summary: Number of transactions processed.

Description: Represents the total number of transaction acceptance, transaction rejection, package upload, party allocation, etc. events processed.

Type: Meter

Qualification: Debug

Labels:

- **participant_id:** The id of the participant.
- **application_id:** The application generating the events.
- **event_type:** The type of ledger event processed (transaction, package upload, party allocation, configuration change).
- **status:** Indicates if the transaction was accepted or not. Possible values accepted|rejected.

29.4.1.112 `daml.indexer.last_received_record_time`

Summary: The time of the last event ingested by the index db (in milliseconds since EPOCH).

Description: The last received record time is a monotonically increasing integer value that represents the record time of the last event ingested by the index db. It is measured in milliseconds since the EPOCH time.

Type: Gauge

Qualification: Debug

29.4.1.113 `daml.indexer.ledger_end_sequential_id`

Summary: The sequential id of the current ledger end kept in the database.

Description: The ledger end's sequential id is a monotonically increasing integer value representing the sequential id ascribed to the most recent ledger event ingested by the index db. Please note, that only a subset of all ledger events are ingested and given a sequential id. These are: creates, consuming exercises, non-consuming exercises and divulgence events. This value can be treated as a counter of all such events visible to a given participant. This metric exposes the latest ledger end's sequential id registered in the database.

Type: Gauge

Qualification: Debug

29.4.1.114 `daml.indexer.metered_events*`

Summary: Number of ledger events that are metered.

Description: Represents the number of events that will be included in the metering report. This is an estimate of the total number and not a substitute for the metering report.

Type: Meter

Qualification: Debug

Labels:

- **participant_id:** The id of the participant.
- **application_id:** The application generating the events.

29.4.1.115 `daml.lapi.streams.acs_sent`

Summary: The number of the active contracts sent by the ledger api.

Description: The total number of active contracts sent over the ledger api streams to all clients.

Type: Counter

Qualification: Traffic

29.4.1.116 `daml.lapi.streams.active`

Summary: The number of the active streams served by the ledger api.

Description: The number of ledger api streams currently being served to all clients.

Type: Gauge

Qualification: Debug

29.4.1.117 `daml.lapi.streams.completions_sent`

Summary: The number of the command completions sent by the ledger api.

Description: The total number of completions sent over the ledger api streams to all clients.

Type: Counter

Qualification: Traffic

29.4.1.118 `daml.lapi.streams.transaction_trees_sent`

Summary: The number of the transaction trees sent over the ledger api.

Description: The total number of the transaction trees sent over the ledger api streams to all clients.

Type: Counter

Qualification: Traffic

29.4.1.119 `daml.lapi.streams.transactions_sent`

Summary: The number of the flat updates sent over the ledger api.

Description: The total number of the flat updates sent over the ledger api streams to all clients.

Type: Counter

Qualification: Traffic

29.4.1.120 `daml.lapi.streams.update_trees_sent`

Summary: The number of the update trees sent over the ledger api.

Description: The total number of the update trees sent over the ledger api streams to all clients.

Type: Counter

Qualification: Traffic

29.4.1.121 `daml.parallel_indexer.archivals`

Summary: The number of archive events persisted to the database.

Description: The number of archive events persisted to the database.

Type: Counter

Qualification: Traffic

29.4.1.122 `daml.parallel_indexer.createes`

Summary: The number of create events persisted to the database.

Description: The number of create events persisted to the database.

Type: Counter

Qualification: Traffic

29.4.1.123 `daml.parallel_indexer.input_buffer_length`

Summary: The number of elements in the queue in front of the indexer.

Description: The indexer has a queue in order to absorb the back pressure and facilitate batch formation during the database ingestion.

Type: Counter

Qualification: Saturation

29.4.1.124 `daml.parallel_indexer.inputmapping.batch_size`

Summary: The batch sizes in the indexer.

Description: The number of state updates contained in a batch used in the indexer for database submission.

Type: Histogram

Qualification: Debug

29.4.1.125 `daml.parallel_indexer.output_batched_buffer_length`

Summary: The size of the queue between the indexer and the in-memory state updating flow.

Description: This counter counts batches of updates passed to the in-memory flow. Batches are dynamically-sized based on amount of backpressure exerted by the downstream stages of the flow.

Type: Counter

Qualification: Debug

29.4.1.126 `daml.parallel_indexer.seqmapping.duration`

Summary: The duration of the seq-mapping stage.

Description: The time that a batch of updates spends in the seq-mapping stage of the indexer.

Type: Timer

Qualification: Debug

29.4.1.127 `daml.parallel_indexer.updates`

Summary: The number of the state updates persisted to the database.

Description: The number of the state updates persisted to the database. There are updates such as accepted transactions, configuration changes, package uploads, party allocations, rejections, etc.

Type: Counter

Qualification: Traffic

29.4.1.128 `daml.services.index.<operation>`

Summary: The time to execute an index service operation.

Description: The index service is an internal component responsible for access to the index db data. Its operations are invoked whenever a client request received over the ledger api requires access to the index db. This metric captures time statistics of such operations.

Type: Timer

Qualification: Debug

Instances: `get_transaction_metering`, `prune`, `configuration_entries`, `lookup_configuration`, `party_entries`, `list_known_parties`, `get_parties`, `get_participant_id`, `lookup_maximum_ledger_time`, `get_events_by_contract_key`, `get_events_by_contract_id`, `lookup_contract_key`, `lookup_contract_state_without_divulgence`, `lookup_active_contract`, `get_active_contracts`, `get_transaction_tree_by_id`, `get_transaction_by_id`, `transaction_trees`, `transactions`, `get_completions_limited`, `get_completions`, `latest_pruned_offsets`, `current_ledger_end`, `get_ledger_configuration`, `package_entries`, `get_if_archive`, `list_if_packages`

29.4.1.129 `daml.services.index.in_memory_fan_out_buffer.prune`

Summary: The time to remove all elements from the in-memory fan-out buffer.

Description: It is possible to remove the oldest entries of the in-memory fan out buffer. This metric exposes the time needed to prune the buffer.

Type: Timer

Qualification: Debug

29.4.1.130 `daml.services.index.in_memory_fan_out_buffer.push`

Summary: The time to add a new event into the buffer.

Description: The in-memory fan-out buffer is a buffer that stores the last ingested `maxBufferSize` accepted and rejected submission updates as `TransactionLogUpdate`. It allows bypassing `IndexDB` persistence fetches for recent updates for flat and transaction tree streams, command completion streams and by-event-id and by-transaction-id flat and transaction tree lookups. This metric exposes the time spent on adding a new event into the buffer.

Type: Timer

Qualification: Debug

29.4.1.131 `daml.services.index.in_memory_fan_out_buffer.size`

Summary: The size of the in-memory fan-out buffer.

Description: The actual size of the in-memory fan-out buffer. This metric is mostly targeted for debugging purposes.

Type: Histogram

Qualification: Saturation

29.4.1.132 `daml.services.read.<operation>`

Summary: The time to execute a read service operation.

Description: The read service is an internal interface for reading the events from the synchronization interfaces. The metrics expose the time needed to execute each operation.

Type: Timer

Qualification: Debug

Instances: `validate_dar`, `get_connected_domains`, `state_updates`

29.4.1.133 `daml.services.write.<operation>`

Summary: The time to execute a write service operation.

Description: The write service is an internal interface for changing the state through the synchronization services. The methods in this interface are all methods that are supported uniformly across all ledger implementations. This metric exposes the time needed to execute each operation.

Type: Timer

Qualification: Debug

Instances: `prune`, `submit_configuration`, `allocate_party`, `upload_packages`, `submit_reassignment_running`, `submit_reassignment`, `submit_transaction_running`, `submit_transaction`

29.4.1.134 `daml.services.write.submit_transaction.count`

Summary: The number of submitted transactions by the write service.

Description: The write service is an internal interface for changing the state through the synchronization services. The methods in this interface are all methods that are supported uniformly across all ledger implementations. This metric exposes the total number of the submitted transactions.

Type: Timer

Qualification: Traffic

29.4.2 Synchronization Domain Metrics

29.4.2.1 `canton.<component>.sequencer-client.application-handle`

Summary: Timer monitoring time and rate of sequentially handling the event application logic

Description: All events are received sequentially. This handler records the the rate and time it takes the application (participant or domain) to handle the events.

Type: Timer

Qualification: Debug

Instances: topology-manager, mediator, sequencer

29.4.2.2 `canton.<component>.sequencer-client.delay`

Summary: The delay on the event processing

Description: Every message received from the sequencer carries a timestamp that was assigned by the sequencer when it sequenced the message. This timestamp is called the sequencing timestamp. The component receiving the message on the participant, mediator or topology manager side, is the sequencer client. Upon receiving the message, the sequencer client compares the time difference between the sequencing time and the computers local clock and exposes this difference as the given metric. The difference will include the clock-skew and the processing latency between assigning the timestamp on the sequencer and receiving the message by the recipient. If the difference is large compared to the usual latencies and if clock skew can be ruled out, then it means that the node is still trying to catch up with events that were sequenced by the sequencer a while ago. This can happen after having been offline for a while or if the node is too slow to keep up with the messaging load.

Type: Gauge

Qualification: Debug

Instances: topology-manager, mediator, sequencer

29.4.2.3 `canton.<component>.sequencer-client.event-handle`

Summary: Timer monitoring time and rate of entire event handling

Description: Most event handling cost should come from the application-handle. This timer measures the full time (which should just be marginally more than the application handle.

Type: Timer

Qualification: Debug

Instances: topology-manager, mediator, sequencer

29.4.2.4 `canton.db-storage.<service>.executor.exectime`

Summary: Execution time metric for database tasks

Description: The time a task is running on the database is measured using this metric.

Type: Timer

Qualification: Debug

Instances: locks, write, general

29.4.2.5 `canton.db-storage.<service>.executor.load`

Summary: Load of database pool

Description: Database queries run as tasks on an async executor. This metric shows the current number of queries running in parallel divided by the number database connections for this database connection pool.

Type: Gauge

Qualification: Debug

Instances: locks, write, general

29.4.2.6 `canton.db-storage.<service>.executor.queued`

Summary: Number of database access tasks waiting in queue

Description: Database access tasks get scheduled in this queue and get executed using one of the existing asynchronous sessions. A large queue indicates that the database connection is not able to deal with the large number of requests. Note that the queue has a maximum size. Tasks that do not fit into the queue will be retried, but won't show up in this metric.

Type: Counter

Qualification: Debug

Instances: locks, write, general

29.4.2.7 `canton.db-storage.<service>.executor.running`

Summary: Number of database access tasks currently running

Description: Database access tasks run on an async executor. This metric shows the current number of tasks running in parallel.

Type: Gauge

Qualification: Debug

Instances: locks, write, general

29.4.2.8 `canton.db-storage.<service>.executor.waittime`

Summary: Scheduling time metric for database tasks

Description: Every database query is scheduled using an asynchronous executor with a queue. The time a task is waiting in this queue is monitored using this metric.

Type: Timer

Qualification: Debug

Instances: locks, write, general

29.4.2.9 `canton.db-storage.<storage>`

Summary: Timer monitoring duration and rate of accessing the given storage

Description: Covers both read from and writes to the storage.

Type: Timer

Qualification: Debug

29.4.2.10 `canton.db-storage.<storage>.load`

Summary: The load on the given storage

Description: The load is a factor between 0 and 1 describing how much of an existing interval has been spent reading from or writing to the storage.

Type: Gauge

Qualification: Debug

29.4.2.11 `canton.db-storage.alerts.multi-domain-event-log`

Summary: Number of failed writes to the multi-domain event log

Description: Failed writes to the multi domain event log indicate an issue requiring user intervention. In the case of domain event logs, the corresponding domain no longer emits any subsequent events until domain recovery is initiated (e.g. by disconnecting and reconnecting the participant from the domain). In the case of the participant event log, an operation might need to be reissued. If this counter is larger than zero, check the canton log for errors for details.

Type: Counter

Qualification: Debug

29.4.2.12 `canton.db-storage.alerts.single-dimension-event-log`

Summary: Number of failed writes to the event log

Description: Failed writes to the single dimension event log indicate an issue requiring user intervention. In the case of domain event logs, the corresponding domain no longer emits any subsequent events until domain recovery is initiated (e.g. by disconnecting and reconnecting the participant from the domain). In the case of the participant event log, an operation might need to be reissued. If this counter is larger than zero, check the canton log for errors for details.

Type: Counter

Qualification: Debug

29.4.2.13 `canton.mediator.event-rejected`

Summary: Event rejected because of traffic limit exceeded

Description: This metric is being incremented every time a sequencer rejects an event because the sender does not have enough credit.

Type: Meter

Qualification: Traffic

29.4.2.14 `canton.mediator.max-event-age`

Summary: Age of oldest unpruned mediator response.

Description: This gauge exposes the age of the oldest, unpruned mediator response in hours as a way to quantify the pruning backlog.

Type: Gauge

Qualification: Debug

29.4.2.15 `canton.mediator.outstanding-requests`

Summary: Number of currently outstanding requests

Description: This metric provides the number of currently open requests registered with the mediator.

Type: Gauge

Qualification: Debug

29.4.2.16 `canton.mediator.requests`

Summary: Number of totally processed requests

Description: This metric provides the number of totally processed requests since the system has been started.

Type: Meter

Qualification: Debug

29.4.2.17 `canton.mediator.sequencer-client.handler.actual-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks how many such batches are processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Indicators that the configured upper bound may be too low: This metric constantly is closed to the configured maximum, which is exposed via 'max-in-flight-event-batches', while the system's resources are under-utilized. Indicators that the configured upper bound may be too high: Out-of-memory errors crashing the JVM or frequent garbage collection cycles that slow down processing. The metric tracks how many of these batches have been sent to the application handler but have not yet been fully processed. This metric can help identify potential bottlenecks or issues with the application's processing of events and provide insights into the overall workload of the system.

Type: Counter

Qualification: Saturation

29.4.2.18 `canton.mediator.sequencer-client.handler.max-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks the upper bound of such batches being processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Configured by 'maximum-in-flight-event-batches' parameter in the sequencer-client config. The metric shows the configured upper limit on how many batches the application handler may process concurrently. The metric 'actual-in-flight-event-batches' tracks the actual number of currently processed batches.

Type: Gauge

Qualification: Saturation

29.4.2.19 `canton.mediator.sequencer-client.submissions.dropped`

Summary: Count of send requests that did not cause an event to be sequenced

Description: Counter of send requests we did not witness a corresponding event to be sequenced by the supplied max-sequencing-time. There could be many reasons for this happening: the request may have been lost before reaching the sequencer, the sequencer may be at capacity and the max-sequencing-time was exceeded by the time the request was processed, or the supplied max-sequencing-time may just be too small for the sequencer to be able to sequence the request.

Type: Counter

Qualification: Debug

29.4.2.20 `canton.mediator.sequencer-client.submissions.in-flight`

Summary: Number of sequencer send requests we have that are waiting for an outcome or timeout

Description: Incremented on every successful send to the sequencer. Decrementing when the event or an error is sequenced, or when the max-sequencing-time has elapsed.

Type: Counter

Qualification: Debug

29.4.2.21 `canton.mediator.sequencer-client.submissions.overloaded`

Summary: Count of send requests which receive an overloaded response

Description: Counter that is incremented if a send request receives an overloaded response from the sequencer.

Type: Counter

Qualification: Debug

29.4.2.22 `canton.mediator.sequencer-client.submissions.sends`

Summary: Rate and timings of send requests to the sequencer

Description: Provides a rate and time of how long it takes for send requests to be accepted by the sequencer. Note that this is just for the request to be made and not for the requested event to actually be sequenced.

Type: Timer

Qualification: Debug

29.4.2.23 `canton.mediator.sequencer-client.submissions.sequencing`

Summary: Rate and timings of sequencing requests

Description: This timer is started when a submission is made to the sequencer and then completed when a corresponding event is witnessed from the sequencer, so will encompass the entire duration for the sequencer to sequence the request. If the request does not result in an event no timing will be recorded.

Type: Timer

Qualification: Debug

29.4.2.24 `canton.sequencer.block.event-bytes`

Summary: Event bytes processed by the sequencer, tagged by type and sender.

Description: Similar to events, except measured by bytes.

Type: Meter

Qualification: Traffic

29.4.2.25 `canton.sequencer.block.events`

Summary: Events processed by the sequencer, tagged by type and sender

Description: The sequencer forwards opaque, possibly encrypted payload. However, by looking at the recipient list, the type of message can still be inferred, and tagged appropriately, including the sender.

Type: Meter

Qualification: Traffic

29.4.2.26 `canton.sequencer.block.height`

Summary: Current block height processed

Description: The submission messages are processed in blocks, where each block has an increasing number. The metric shows the height of the last processed block by the given sequencer node.

Type: Gauge

Qualification: Traffic

29.4.2.27 `canton.sequencer.db-storage.<storage>`

Summary: Timer monitoring duration and rate of accessing the given storage

Description: Covers both read from and writes to the storage.

Type: Timer

Qualification: Debug

29.4.2.28 `canton.sequencer.db-storage.<storage>.load`

Summary: The load on the given storage

Description: The load is a factor between 0 and 1 describing how much of an existing interval has been spent reading from or writing to the storage.

Type: Gauge

Qualification: Debug

29.4.2.29 `canton.sequencer.db-storage.alerts.multi-domain-event-log`

Summary: Number of failed writes to the multi-domain event log

Description: Failed writes to the multi domain event log indicate an issue requiring user intervention. In the case of domain event logs, the corresponding domain no longer emits any subsequent events until domain recovery is initiated (e.g. by disconnecting and reconnecting the participant from the domain). In the case of the participant event log, an operation might need to be reissued. If this counter is larger than zero, check the canton log for errors for details.

Type: Counter

Qualification: Debug

29.4.2.30 `canton.sequencer.db-storage.alerts.single-dimension-event-log`

Summary: Number of failed writes to the event log

Description: Failed writes to the single dimension event log indicate an issue requiring user intervention. In the case of domain event logs, the corresponding domain no longer emits any subsequent events until domain recovery is initiated (e.g. by disconnecting and reconnecting the participant from the domain). In the case of the participant event log, an operation might need to be reissued. If this counter is larger than zero, check the canton log for errors for details.

Type: Counter

Qualification: Debug

29.4.2.31 `canton.sequencer.db-storage.general.executor.exectime`

Summary: Execution time metric for database tasks

Description: The time a task is running on the database is measured using this metric.

Type: Timer

Qualification: Debug

29.4.2.32 `canton.sequencer.db-storage.general.executor.load`

Summary: Load of database pool

Description: Database queries run as tasks on an async executor. This metric shows the current number of queries running in parallel divided by the number database connections for this database connection pool.

Type: Gauge

Qualification: Debug

29.4.2.33 `canton.sequencer.db-storage.general.executor.queued`

Summary: Number of database access tasks waiting in queue

Description: Database access tasks get scheduled in this queue and get executed using one of the existing asynchronous sessions. A large queue indicates that the database connection is not able to deal with the large number of requests. Note that the queue has a maximum size. Tasks that do not fit into the queue will be retried, but won't show up in this metric.

Type: Counter

Qualification: Debug

29.4.2.34 `canton.sequencer.db-storage.general.executor.running`

Summary: Number of database access tasks currently running

Description: Database access tasks run on an async executor. This metric shows the current number of tasks running in parallel.

Type: Gauge

Qualification: Debug

29.4.2.35 `canton.sequencer.db-storage.general.executor.waittime`

Summary: Scheduling time metric for database tasks

Description: Every database query is scheduled using an asynchronous executor with a queue. The time a task is waiting in this queue is monitored using this metric.

Type: Timer

Qualification: Debug

29.4.2.36 `canton.sequencer.db-storage.locks.executor.exectime`

Summary: Execution time metric for database tasks

Description: The time a task is running on the database is measured using this metric.

Type: Timer

Qualification: Debug

29.4.2.37 `canton.sequencer.db-storage.locks.executor.load`

Summary: Load of database pool

Description: Database queries run as tasks on an async executor. This metric shows the current number of queries running in parallel divided by the number database connections for this database connection pool.

Type: Gauge

Qualification: Debug

29.4.2.38 `canton.sequencer.db-storage.locks.executor.queued`

Summary: Number of database access tasks waiting in queue

Description: Database access tasks get scheduled in this queue and get executed using one of the existing asynchronous sessions. A large queue indicates that the database connection is not able to deal with the large number of requests. Note that the queue has a maximum size. Tasks that do not fit into the queue will be retried, but won't show up in this metric.

Type: Counter

Qualification: Debug

29.4.2.39 `canton.sequencer.db-storage.locks.executor.running`

Summary: Number of database access tasks currently running

Description: Database access tasks run on an async executor. This metric shows the current number of tasks running in parallel.

Type: Gauge

Qualification: Debug

29.4.2.40 `canton.sequencer.db-storage.locks.executor.waittime`

Summary: Scheduling time metric for database tasks

Description: Every database query is scheduled using an asynchronous executor with a queue. The time a task is waiting in this queue is monitored using this metric.

Type: Timer

Qualification: Debug

29.4.2.41 `canton.sequencer.db-storage.write.executor.exectime`

Summary: Execution time metric for database tasks

Description: The time a task is running on the database is measured using this metric.

Type: Timer

Qualification: Debug

29.4.2.42 `canton.sequencer.db-storage.write.executor.load`

Summary: Load of database pool

Description: Database queries run as tasks on an async executor. This metric shows the current number of queries running in parallel divided by the number database connections for this database connection pool.

Type: Gauge

Qualification: Debug

29.4.2.43 `canton.sequencer.db-storage.write.executor.queued`

Summary: Number of database access tasks waiting in queue

Description: Database access tasks get scheduled in this queue and get executed using one of the existing asynchronous sessions. A large queue indicates that the database connection is not able to deal with the large number of requests. Note that the queue has a maximum size. Tasks that do not fit into the queue will be retried, but won't show up in this metric.

Type: Counter

Qualification: Debug

29.4.2.44 `canton.sequencer.db-storage.write.executor.running`

Summary: Number of database access tasks currently running

Description: Database access tasks run on an async executor. This metric shows the current number of tasks running in parallel.

Type: Gauge

Qualification: Debug

29.4.2.45 `canton.sequencer.db-storage.write.executor.waittime`

Summary: Scheduling time metric for database tasks

Description: Every database query is scheduled using an asynchronous executor with a queue. The time a task is waiting in this queue is monitored using this metric.

Type: Timer

Qualification: Debug

29.4.2.46 `canton.sequencer.max-event-age`

Summary: Age of oldest unpruned sequencer event.

Description: This gauge exposes the age of the oldest, unpruned sequencer event in hours as a way to quantify the pruning backlog.

Type: Gauge

Qualification: Debug

29.4.2.47 `canton.sequencer.processed`

Summary: Number of messages processed by the sequencer

Description: This metric measures the number of successfully validated messages processed by the sequencer since the start of this process.

Type: Meter

Qualification: Debug

29.4.2.48 `canton.sequencer.processed-bytes`

Summary: Number of message bytes processed by the sequencer

Description: This metric measures the total number of message bytes processed by the sequencer. If the message received by the sequencer contains duplicate or irrelevant fields, the contents of these fields do not contribute to this metric.

Type: Meter

Qualification: Debug

29.4.2.49 `canton.sequencer.sequencer-client.handler.actual-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks how many such batches are processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Indicators that the configured upper bound may be too low: This metric constantly is closed to the configured maximum, which is exposed via 'max-in-flight-event-batches', while the system's resources are under-utilized. Indicators that the configured upper bound may be too high: Out-of-memory errors crashing the JVM or frequent garbage collection cycles that slow down processing. The metric tracks how many of these batches have been sent to the application handler but have not yet been fully processed. This metric can help identify potential bottlenecks or issues with the application's processing of events and provide insights into the overall workload of the system.

Type: Counter

Qualification: Saturation

29.4.2.50 `canton.sequencer.sequencer-client.handler.max-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks the upper bound of such batches being processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Configured by 'maximum-in-flight-event-batches' parameter in the sequencer-client config The metric shows the configured upper limit on how many batches the application handler may process concurrently. The metric 'actual-in-flight-event-batches' tracks the actual number of currently processed batches.

Type: Gauge

Qualification: Saturation

29.4.2.51 `canton.sequencer.sequencer-client.submissions.dropped`

Summary: Count of send requests that did not cause an event to be sequenced

Description: Counter of send requests we did not witness a corresponding event to be sequenced by the supplied max-sequencing-time. There could be many reasons for this happening: the request may have been lost before reaching the sequencer, the sequencer may be at capacity and the the max-sequencing-time was exceeded by the time the request was processed, or the supplied max-sequencing-time may just be too small for the sequencer to be able to sequence the request.

Type: Counter

Qualification: Debug

29.4.2.52 `canton.sequencer.sequencer-client.submissions.in-flight`

Summary: Number of sequencer send requests we have that are waiting for an outcome or timeout

Description: Incremented on every successful send to the sequencer. Decrementd when the event or an error is sequenced, or when the max-sequencing-time has elapsed.

Type: Counter

Qualification: Debug

29.4.2.53 `canton.sequencer.sequencer-client.submissions.overloaded`

Summary: Count of send requests which receive an overloaded response

Description: Counter that is incremented if a send request receives an overloaded response from the sequencer.

Type: Counter

Qualification: Debug

29.4.2.54 `canton.sequencer.sequencer-client.submissions.sends`

Summary: Rate and timings of send requests to the sequencer

Description: Provides a rate and time of how long it takes for send requests to be accepted by the sequencer. Note that this is just for the request to be made and not for the requested event to actually be sequenced.

Type: Timer

Qualification: Debug

29.4.2.55 `canton.sequencer.sequencer-client.submissions.sequencing`

Summary: Rate and timings of sequencing requests

Description: This timer is started when a submission is made to the sequencer and then completed when a corresponding event is witnessed from the sequencer, so will encompass the entire duration for the sequencer to sequence the request. If the request does not result in an event no timing will be recorded.

Type: Timer

Qualification: Debug

29.4.2.56 `canton.sequencer.subscriptions`

Summary: Number of active sequencer subscriptions

Description: This metric indicates the number of active subscriptions currently open and actively served subscriptions at the sequencer.

Type: Gauge

Qualification: Debug

29.4.2.57 `canton.sequencer.time-requests`

Summary: Number of time requests received by the sequencer

Description: When a Participant needs to know the domain time it will make a request for a time proof to be sequenced. It would be normal to see a small number of these being sequenced, however if this number becomes a significant portion of the total requests to the sequencer it could indicate that the strategy for requesting times may need to be revised to deal with different clock skews and latencies between the sequencer and participants.

Type: Meter

Qualification: Debug

29.4.2.58 `canton.sequencer.traffic-control.event-delivered-cost`

Summary: Cost of delivered event.

Description: Cost of an event that was delivered.

Type: Meter

Qualification: Traffic

29.4.2.59 `canton.sequencer.traffic-control.event-received-size`

Summary: Raw size of an event received in the sequencer.

Description: This the raw payload size of an event, on the write path. Final event cost calculation.

Type: Meter

Qualification: Traffic

29.4.2.60 `canton.sequencer.traffic-control.event-rejected-cost`

Summary: Cost of rejected event.

Description: Cost of an event that was rejected because it exceeded the sender's traffic limit.

Type: Meter

Qualification: Traffic

29.4.2.61 `canton.topology-manager.sequencer-client.handler.actual-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks how many such batches are processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Indicators that the configured upper bound may be too low: This metric constantly is closed to the configured maximum, which is exposed via 'max-in-flight-event-batches', while the system's resources are under-utilized. Indicators that the configured upper bound may be too high: Out-of-memory errors crashing the JVM or frequent garbage collection cycles that slow down processing. The metric tracks how many of these batches have been sent to the application handler but have not yet been fully processed. This metric can help identify potential bottlenecks or issues with the application's processing of events and provide insights into the overall workload of the system.

Type: Counter

Qualification: Saturation

29.4.2.62 `canton.topology-manager.sequencer-client.handler.max-in-flight-event-batches`

Summary: Nodes process the events from the domain's sequencer in batches. This metric tracks the upper bound of such batches being processed in parallel.

Description: Incoming messages are processed by a sequencer client, which combines them into batches of size up to 'event-inbox-size' before sending them to an application handler for processing. Depending on the system's configuration, the rate at which event batches are sent to the handler may be throttled to avoid overwhelming it with too many events at once. Configured by 'maximum-in-flight-event-batches' parameter in the sequencer-client config The metric shows the configured upper limit on how many batches the application handler may process concurrently. The metric 'actual-in-flight-event-batches' tracks the actual number of currently processed batches.

Type: Gauge

Qualification: Saturation

29.4.2.63 `canton.topology-manager.sequencer-client.submissions.dropped`

Summary: Count of send requests that did not cause an event to be sequenced

Description: Counter of send requests we did not witness a corresponding event to be sequenced by the supplied max-sequencing-time. There could be many reasons for this happening: the request may have been lost before reaching the sequencer, the sequencer may be at capacity and the the max-sequencing-time was exceeded by the time the request was processed, or the supplied max-sequencing-time may just be too small for the sequencer to be able to sequence the request.

Type: Counter

Qualification: Debug

29.4.2.64 `canton.topology-manager.sequencer-client.submissions.in-flight`

Summary: Number of sequencer send requests we have that are waiting for an outcome or timeout

Description: Incremented on every successful send to the sequencer. Decrementd when the event or an error is sequenced, or when the max-sequencing-time has elapsed.

Type: Counter

Qualification: Debug

29.4.2.65 `canton.topology-manager.sequencer-client.submissions.overloaded`

Summary: Count of send requests which receive an overloaded response

Description: Counter that is incremented if a send request receives an overloaded response from the sequencer.

Type: Counter

Qualification: Debug

29.4.2.66 `canton.topology-manager.sequencer-client.submissions.sends`

Summary: Rate and timings of send requests to the sequencer

Description: Provides a rate and time of how long it takes for send requests to be accepted by the sequencer. Note that this is just for the request to be made and not for the requested event to actually be sequenced.

Type: Timer

Qualification: Debug

29.4.2.67 `canton.topology-manager.sequencer-client.submissions.sequencing`

Summary: Rate and timings of sequencing requests

Description: This timer is started when a submission is made to the sequencer and then completed when a corresponding event is witnessed from the sequencer, so will encompass the entire duration for the sequencer to sequence the request. If the request does not result in an event no timing will be recorded.

Type: Timer

Qualification: Debug

29.4.3 Health Metrics

The following metrics are exposed for all components.

29.4.3.1 daml_health_status

Description: The status of the component

Values:

- **0:** Not healthy
- **1:** Healthy

Labels:

- **component:** the name of the component being monitored

Type: Gauge

29.4.4 gRPC Metrics

The following metrics are exposed for all gRPC endpoints. These metrics have the following common labels attached:

grpc_service_name: fully qualified name of the gRPC service (e.g. `com.daml.ledger.api.v1.ActiveContractsService`)

grpc_method_name: name of the gRPC method (e.g. `GetActiveContracts`)

grpc_client_type: type of client connection (unary or streaming)

grpc_server_type: type of server connection (unary or streaming)

service: Canton service's name (e.g. `participant`, `sequencer`, etc.)

29.4.4.1 daml_grpc_server_duration_seconds

Description: Distribution of the durations of serving gRPC requests

Type: Histogram

29.4.4.2 daml_grpc_server_messages_sent_total

Description: Total number of gRPC messages sent (on either type of connection)

Type: Counter

29.4.4.3 daml_grpc_server_messages_received_total

Description: Total number of gRPC messages received (on either type of connection)

Type: Counter

29.4.4.4 `daml_grpc_server_started_total`

Description: Total number of started gRPC requests (on either type of connection)

Type: Counter

29.4.4.5 `daml_grpc_server_handled_total`

Description: Total number of handled gRPC requests

Labels:

- **grpc_code:** returned [gRPC status code](#) for the call (OK, CANCELLED, INVALID_ARGUMENT, etc.)

Type: Counter

29.4.4.6 `daml_grpc_server_messages_sent_bytes`

Description: Distribution of payload sizes in gRPC messages sent (both unary and streaming)

Type: Histogram

29.4.4.7 `daml_grpc_server_messages_received_bytes`

Description: Distribution of payload sizes in gRPC messages received (both unary and streaming)

Type: Histogram

29.4.5 HTTP Metrics

The following metrics are exposed for all HTTP endpoints. These metrics have the following common labels attached:

http_verb: HTTP verb used for a given call (e.g. GET or PUT)

host: fully qualified hostname of the HTTP endpoint (e.g. `example.com`)

path: path of the HTTP endpoint (e.g. `/v1/parties/create`)

service: Daml service's name (`json_api` for the HTTP JSON API Service)

29.4.5.1 `daml_http_requests_duration_seconds`

Description: Distribution of the durations of serving HTTP requests

Type: Histogram

29.4.5.2 daml_http_requests_total

Description: Total number of HTTP requests completed

Labels:

- **http_status:** returned [HTTP status code](#) for the call

Type: Counter

29.4.5.3 daml_http_websocket_messages_received_total

Description: Total number of WebSocket messages received

Type: Counter

29.4.5.4 daml_http_websocket_messages_sent_total

Description: Total number of WebSocket messages sent

Type: Counter

29.4.5.5 daml_http_requests_payload_bytes

Description: Distribution of payload sizes in HTTP requests received

Type: Histogram

29.4.5.6 daml_http_responses_payload_bytes

Description: Distribution of payload sizes in HTTP responses sent

Type: Histogram

29.4.5.7 daml_http_websocket_messages_received_bytes

Description: Distribution of payload sizes in WebSocket messages received

Type: Histogram

29.4.5.8 daml_http_websocket_messages_sent_bytes

Description: Distribution of payload sizes in WebSocket messages sent

Type: Histogram

29.4.6 Pruning Metrics

The following metrics are exposed for all pruning processes. These metrics have the following labels:

phase: The name of the pruning phase being monitored

29.4.6.1 `daml_services_pruning_prune_started_total`

Description: Total number of started pruning processes

Type: Counter

29.4.6.2 `daml_services_pruning_prune_completed_total`

Description: Total number of completed pruning processes

Type: Counter

29.4.7 JVM Metrics

The following metrics are exposed for the JVM, if enabled.

29.4.7.1 `runtime_jvm_gc_time`

Description: Time spent in a given JVM garbage collector in milliseconds

Labels:

- **gc:** Garbage collector regions (eg: G1 Old Generation, G1 New Generation)

Type: Counter

29.4.7.2 `runtime_jvm_gc_count`

Description: The number of collections that have occurred for a given JVM garbage collector

Labels:

- **gc:** Garbage collector regions (eg: G1 Old Generation, G1 New Generation)

Type: Counter

29.4.7.3 `runtime_jvm_memory_area`

Description: JVM memory area statistics

Labels:

- **area:** Can be `heap` or `non_heap`
- **type:** Can be `committed`, `used` or `max`

29.4.7.4 `runtime_jvm_memory_pool`

Description: JVM memory pool statistics

Labels:

- **pool:** Defined pool name.
- **type:** Can be `committed`, `used` or `max`

29.5 Logging

Canton uses [Logback](#) as the logging library. All Canton logs derive from the logger `com.digitalasset.canton`. By default, Canton will write a log to the file `log/canton.log` using the INFO log-level and will also log WARN and ERROR to stdout.

How Canton produces log files can be configured extensively on the command line using the following options:

- `-v` (or `--verbose`) is a short option to set the Canton log level to `DEBUG`. This is likely the most common log option you will use.
- `--debug` sets all log levels except stdout to `DEBUG`. Stdout is set to `INFO`. Note that `DEBUG` logs of external libraries can be very noisy.
- `--log-level-root=<level>` configures the log-level of the root logger. This changes the log level of Canton and of external libraries, but not of stdout.
- `--log-level-canton=<level>` configures the log-level of only the Canton logger.
- `--log-level-stdout=<level>` configures the log-level of stdout. This will usually be the text displayed in the Canton console.
- `--log-file-name=log/canton.log` configures the location of the log file.
- `--log-file-appender=flat|rolling|off` configures if and how logging to a file should be done. The rolling appender will roll the files according to the defined date-time pattern.
- `--log-file-rolling-history=12` configures the number of historical files to keep when using the rolling appender.
- `--log-file-rolling-pattern=YYYY-mm-dd` configures the rolling file suffix (and therefore the frequency) of how files should be rolled.
- `--log-truncate` configures whether the log file should be truncated on startup.
- `--log-profile=container` provides a default set of logging settings for a particular setup. Only the `container` profile is supported, which logs to both STDOUT and to 10-hour limited rolling log files history (to avoid storage leaks).
- `--log-immediate-flush=false` turns off immediate flushing of the log output to the log file.

Note that if you use `--log-profile`, the order of the command line arguments matters. The profile settings can be overridden on the command line by placing adjustments after the profile has been selected.

Canton supports the normal log4j logging levels: `TRACE`, `DEBUG`, `INFO`, `WARN`, and `ERROR`.

For further customization, a custom [logback configuration](#) can be provided using `JAVA_OPTS`.

```
JAVA_OPTS="-Dlogback.configurationFile=./path-to-file.xml" ./bin/canton --config .
↪ ..
```

If you use a custom log-file, the command line arguments for logging will not have any effect, except that `--log-level-canton` and `--log-level-root` can still be used to adjust the log level of the root loggers.

29.5.1 Viewing Logs

A log file viewer such as [lnav](#) is recommended to view Canton logs and resolve issues. Among other features, lnav has automatic syntax highlighting, convenient filtering for specific log messages, and the ability to view log files of different Canton components in a single view. This makes viewing logs and resolving issues more efficient than using standard UNIX tools such as `less` or `grep`.

The following features are especially useful when using `lnav`:

- Viewing log files of different Canton components in [a single view](#), merged according to timestamps (`lnav <log1> <log2> ...`).

- [Filtering](#) specific log messages in `(:filter-in <regex>)` or out `(:filter-out <regex>)`. When filtering messages (for example, with a given trace-id), a transaction can be traced across different components, especially when using the single-view-feature described earlier.

- [Searching](#) for specific log messages `(/ <regex>)` and jumping between them (`n` and `N`).

- Automatic syntax highlighting of parts of log messages (such as timestamps) and log messages themselves (for example, `WARN` log messages are yellow).

- [Jumping](#) between error (`e` and `E`) and warn messages (`w` and `W`).

- Selectively activating and deactivating different filters and files (`TAB` and ``` ``` to activate/deactivate a filter).

- Marking lines (`m`) and jumping back and forth between marked lines (`u` and `U`).

- Jumping back and forth between lines that have the same [trace-id](#) (`o` and `O`).

The [custom lnav log format file](#) for Canton logs `canton.lnav.json` is bundled in any Canton release. You can install it with `lnav -i canton.lnav.json`. JSON-based log files (which need to use the file suffix `.clog`) can be viewed using the `canton-json.lnav.json` format file.

29.5.2 Detailed Logging

By default, logging omits details to avoid writing sensitive data into log files. For debugging or educational purposes, you can turn on additional logging using the following configuration switches:

```
canton.monitoring.logging {
  event-details = true
  api {
    message-payloads = true
    max-method-length = 1000
    max-message-lines = 10000
    max-string-length = 10000
    max-metadata-size = 10000
  }
}
```

This turns on payload logging in the `ApiRequestLogger`, which records every gRPC API invocation, and turns on detailed logging of the `SequencerClient` and the transaction trees. Please note that all additional events are logged at `DEBUG` level.

Note: Note that the detailed event logging will happen within an gRPC API Interceptor. This creates a sequential bottleneck as every message that is sent or received gets translated into a pretty-printed string. You will not be able to achieve the same performance if this setting is turned on.

29.6 Tracing

For further debugging, Canton provides a trace-id which allows you to trace the processing of requests through the system. The trace-id is exposed to logback through the *mapping diagnostic context* and can be included in the logback output pattern using `%mdc{trace-id}`.

The trace-id propagation is enabled by setting the `canton.monitoring.tracing.propagation = enabled` configuration option, which is enabled by default.

You can configure the service where traces and spans are reported for observing distributed traces. Refer to [Traces](#) for a preview.

Jaeger and Zipkin are supported. For example, Jaeger reporting can be configured as follows:

```
monitoring.tracing.tracer.exporter {
  type = jaeger
  address = ... // default: "localhost"
  port = ... // default: 14250
}
```

This configuration connects to a running Jaeger server to report tracing information.

You can run Jaeger in a Docker container as follows:

```
docker run --rm -it --name jaeger\
  -p 16686:16686 \
  -p 14250:14250 \
  jaegertracing/all-in-one:1.22.0
```

If you prefer not to use Docker, you can download the binary for your specific OS at [Download Jaeger](#). Unzip the file and then run the binary `jaeger-all-in-one` (no arguments are needed). By default, Jaeger will expose port 16686 (for its UI, which can be seen in a browser window) and port 14250 (to which Canton will report trace information). Be sure to properly expose these ports.

Make sure that all Canton nodes in the network report to the same Jaeger server to have an accurate view of the full traces. Also, ensure that the Jaeger server is reachable by all Canton nodes.

Apart from jaeger, Canton nodes can also be configured to report in Zipkin or OTLP formats.

29.6.1 Sampling

You can change how often spans are sampled and reported to the configured exporter. By default, it will always report (`monitoring.tracing.tracer.sampler.type = always-on`). You can configure it to never report (`monitoring.tracing.tracer.sampler.type = always-off`), although this is less useful. Also, you can configure only a specific fraction of spans to be reported as follows:

```
monitoring.tracing.tracer.sampler = {
  type = trace-id-ratio
  ratio = 0.5
}
```

You can also change the parent-based sampling property. By default, it is turned on (`monitoring.tracing.tracer.sampler.parent-based = true`). When turned on, a span is sampled iff its parent is sampled (the root span will follow the configured sampling strategy). There will never be

incomplete traces; either the full trace is sampled or it is not. If you change this property, all spans will follow the configured sampling strategy and ignore whether the parent is sampled.

29.6.2 Known Limitations

Not every trace created which can be observed in logs is reported to the configured trace collector service. Traces originated at console commands or that are part of the transaction protocol are largely reported, while other types of traces are added to the set of reported traces as the need arises.

Also, the transaction protocol trace has a known limitation: once a command is submitted and its trace is fully reported, a new trace is created for any resulting Daml events that are processed. This occurs because the ledger API does not propagate any trace context information from the command submission to the transaction subscription. As an example, when a participant creates a `Ping` contract, you can see the full transaction processing trace of the `Ping` command being submitted. However, a participant that processes the `Ping` by exercising `Respond` and creating a `Pong` contract creates a separate trace instead of using the same one.

This differs from a situation where a single Daml transaction results in multiple actions at the same time, such as archiving and creating multiple contracts. In that case, a single trace encompasses the entire process, since it occurs as part of a single transaction rather than the result of an external process reacting to Daml events.

29.6.3 Traces

Traces contain operations that are each represented by a span. A trace is a directed acyclic graph (DAG) of spans, where the edges between spans are defined as parent/child relationships (the definitions come from the [Opentelemetry glossary](#)).

Canton reports several types of traces. One example: every Canton console command that interacts with the Admin API starts a trace whose initial span last for the entire duration of the command, including the GRPC call to the specific Admin API endpoint.

Traces of Daml command submissions are important. The trace illustrated in the figure results when you perform a Canton ping using the console. The ping is a smoke test that sends a Daml transaction (create `Ping`, exercise choice `Pong`, exercise choice `Archive`) to test a connection. It uses a particular smart contract that is preinstalled on every Canton participant. The command uses the Admin API to access a preinstalled application, which then issues Ledger API commands operating on this smart contract. In this example, the trace contains 18 spans. The ping is started by `participant1`, and `participant2` is the target. The trace focuses on the message exchange through the sequencer without digging deep into the message handlers or further processing of transactions.

In some cases, spans may start later than the end of their parents, due to asynchronous processing. This typically occurs when a new operation is placed on a queue to be handled later, which immediately frees the parent span and ends it.

The initial span (span 1) covers the duration of the ping operation. In span 2, the `GrpcPingService` in the participant node handles a GRPC request made by the console. It also lasts for the duration of the ping operation.

The Canton ping consists of three Daml commands:

1. The admin party for `participant1` creates a `Ping` contract.
2. The admin party for `participant2` exercises the `Respond` consuming choice on the contract, which results in the creation of a `Pong` contract.

Fig. 2: Graph of a Canton ping trace containing 18 spans

3. The admin party for `participant1` exercises the `Ack` consuming choice on it.

The submission of the first of the three Daml commands (the creation of the Ping contract) starts at span 3 in the example trace. Due to a limitation explained in the next section, the other two Daml command submissions are not linked to this trace. It is possible to find them separately. In any case, span 2 will only complete once the three Daml commands are completed.

At span 3, the participant node is on the client side of the ledger API. In other use cases, it could be an application integrated with the participant. This span lasts for the duration of the GRPC call, which is received on the server side in span 4 and handled by the `CantonSyncService` in span 5. The request is then received and acknowledged, but not fully processed. It is processed asynchronously later, which means that spans 3 through 5 will complete before the request is handled.

Missing steps from the trace (which account for part of the gap between spans 5 and 6) are:

- The sync domain routing where the participant decides which sync domain to use for the command submission.

- The preparation of the initial set of messages to be sent.

The start of the Canton transaction protocol begins at span 6. In this span, `participant1` sends a request to `sequencer1` to sequence the initial set of confirmation request messages as part of phase 1 of the transaction protocol. The transaction protocol has [seven phases](#).

At span 7, `sequencer1` receives the request and registers it. Receipt of the messages is not part of this span. That happens asynchronously at a later point.

At span 18, as part of phase 2, `mediator1` receives an informee message. It only needs to validate and register it. Since it doesn't need to respond, span 18 has no children.

As part of phase 3, `participant2` receives a message (see span 8), and `participant1` also receives a message (see span 9). Both participants asynchronously validate the messages. `participant2` does not need to respond. Since it is only an observer, span 8 has no children. `participant1` responds, however, which is visible at span 10. There, it again makes a call to `sequencer1`, which

receives it at span 11.

At span 12, `participant1` receives a successful send response message that signals that its message to the mediator was successfully sequenced. This occurs as part of phase 4, where confirmation responses are sent to the mediator. The mediator receives it at span 13, and it validates the message (phase 5).

In spans 14 and 15, `mediator1` (now at phase 6) asks `sequencer1` to send the transaction result messages to the participants.

To end this round of the transaction protocol, `participant1` and `participant2` receive their messages at spans 16 and 17, respectively. The messages are asynchronously validated, and their projections of the virtual shared ledger are updated (phase 7).

As mentioned, there are two other transaction submissions that are unlinked from this ping trace but are part of the operation. The second one starts at a span titled `admin-ping.processTransaction`, which is created by `participant2`. The third one has the same name but is initiated by `participant1`.

29.7 Node Health Status

Each Canton node exposes rich health status information. Running:

```
<node>.health.status
```

returns a status object, which can be one of:

- `Failure`: if the status of the node cannot be determined, including an error message of why it failed

- `NotInitialized`: if the node is not yet initialized

- `Success[NodeStatus]`: if the status could be determined, including the detailed status

The `NodeStatus` differs depending on the node type. A participant node responds with a message containing:

- `Participant id`: the participant id of the node

- `Uptime`: the uptime of this node

- `Ports`: the ports on which the participant node exposes the Ledger and the Admin API.

- `Connected domains`: the list of sync domains to which the participant is properly connected

- `Unhealthy domains`: the list of sync domains to which the participant is trying to connect, but the connection is not ready for command submission

- `Active`: true if this instance is the active replica (It can be false in the case of the passive instance of a high-availability deployment.)

A sync domain node or a sequencer node responds with a message containing:

- `Domain id`: the unique identifier of the sync domain

- `Uptime`: the uptime of this node

- `Ports`: the ports on which the sync domain exposes the Public and the Admin API

- `Connected Participants`: the list of connected participants

- `Sequencer`: a boolean flag indicating whether the embedded sequencer writer is operational

A sequencer node also returns the following additional field starting from Canton 2.8.6:

- `Accepts admin changes`: a boolean flag indicating whether the sequencer accepts admin changes

A sync domain topology manager or a mediator node returns:

- Node uid: the unique identifier of the node
- Uptime: the uptime of this node
- Ports: the ports on which the node hosts its APIs
- Active: true if this instance is the active replica (It can be false in the case of the passive instance of a high-availability deployment.)

Additionally, all nodes also return a `components` field detailing the health state of each of its internal runtime dependencies. The actual components differ per node and can give further insights into the node's current status. Example components include storage access, sync domain connectivity, and sequencer backend connectivity.

29.8 Health Checks

29.8.1 gRPC Health Check Service

Each Canton node can optionally be configured to start a gRPC server exposing the [gRPC Health Service](#). Passive nodes (see [High Availability](#) for more information on active/passive states) return `NOT_SERVING`. Consider this when configuring [liveness and readiness probes in a Kubernetes environment](#).

The precise way the state is computed is subject to change.

Here is an example monitoring configuration to place inside a node configuration object:

```
monitoring.grpc-health-server {  
  address = "127.0.0.1"  
  port = 5861  
}
```

Note: The gRPC health server is configured per Canton node, not per process, as is the case for the HTTP health check server (see below). This means that the configuration must be inserted within a node's configuration object.

Note: To support usage as a Kubernetes liveness probe, the health server exposes a service named `liveness` that should be targeted when [configuring a gRPC probe](#). The latter service always returns `SERVING`.

29.8.2 HTTP Health Check

Optionally, the `canton` process can expose an HTTP endpoint indicating whether the process believes it is healthy. This may be used as an uptime check or as a [Kubernetes liveness probe](#). If enabled, the `/health` endpoint will respond to a GET HTTP request with a 200 HTTP status code (if healthy) or 500 (if unhealthy, along with a plain text description of why it is unhealthy).

To enable this health endpoint, add a `monitoring` section to the Canton configuration. Since this health check is for the whole process, add it directly to the `canton` configuration rather than for a specific node.

```
canton {  
  monitoring.health {  
    server {  
      port = 7000  
    }  
  
    check {  
      type = ping  
      participant = participant1  
      interval = 30s  
    }  
  }  
}
```

This health check causes `participant1` to ledger ping itself every 30 seconds. The process is considered healthy if the ping is successful.

29.9 Health Dumps

You should provide as much information as possible to receive efficient support. For this purpose, Canton implements an information-gathering facility that gathers key essential system information for support staff. If you encounter an error where you need assistance, please ensure the following:

- Start Canton in interactive mode, with the `-v` option to enable debug logging: `./bin/canton -v -c <myconfig>`. This provides a console prompt.

- Reproduce the error by following the steps that previously caused the error. Write down these steps so they can be provided to support staff.

- After you observe the error, type `health.dump()` into the Canton console to generate a ZIP file.

This creates a dump file (`.zip`) that stores the following information:

- The configuration you are using, with all sensitive data stripped from it (no passwords).
- An extract of the log file. Sensitive data is not logged into log files.
- A current snapshot on Canton metrics.
- A stacktrace for each running thread.

Provide the gathered information to your support contact together with the exact list of steps that led to the issue. Providing complete information is very important to help troubleshoot issues.

29.9.1 Remote Health Dumps

When running a console configured to access remote nodes, the `health.dump()` command gathers health data from the remote nodes and packages them into resulting zip files. There is no special action required. You can obtain the health data of a specific node by targeting it when running the command. For example:

```
remoteParticipant1.health.dump()
```

When packaging large amounts of data, increase the default timeout of the dump command:

```
health.dump(timeout = 2.minutes)
```

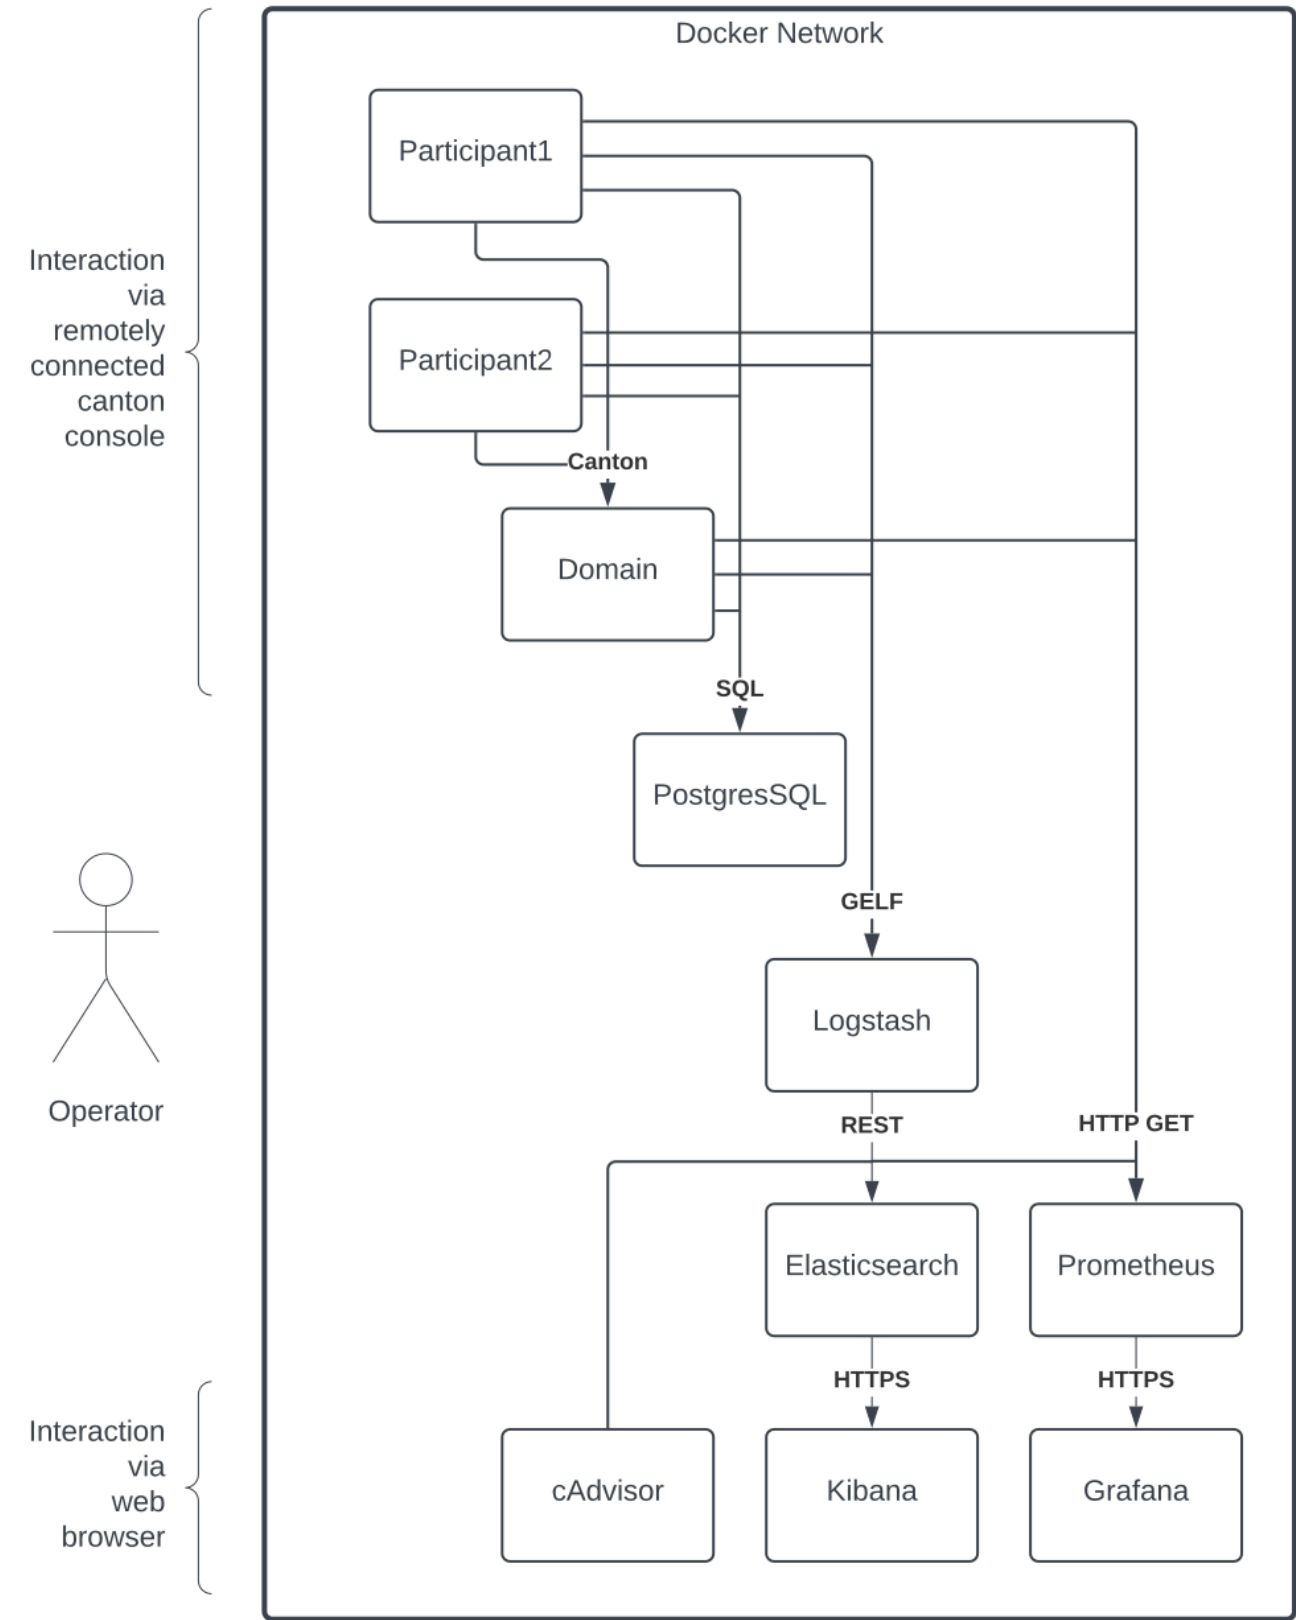

29.10 Example Monitoring Setup

This section provides an example of how Canton can be run inside a connected network of Docker containers. The example also shows how you can monitor network activity. See the [monitoring glossary](#) for an explanation of the terms and the [Monitoring Choices](#) section for the reasoning behind the example monitoring setup.

29.10.1 Container Setup

To configure [Docker Compose](#) to spin up the Docker container network shown in the diagram, use the information below. See the [compose](#) documentation for detailed information concerning the structure of the configuration files.

`compose` allows you to provide the overall configuration across multiple files. Each configuration file is described below, followed by information on how to bring them together in a running network.

29.10.1.1 Intended Use

This example is intended to demonstrate how to expose, aggregate, and observe monitoring information from Canton. It is not suitable for production without alterations. Note the following warnings:

Warning: Ports are exposed from the Docker network that are not necessary to support the UI. For example, the network can allow low-level interaction with the underlying service via a REST or similar interface. In a production system, the only ports that should be exposed are those required for the operation of the system.

Warning: Some of the services used in the example (for example, Postgres and Elasticsearch) persist data to disk. For this example, the volumes used for this persisted data are internal to the Docker container. This means that when the Docker network is torn down, all data is cleaned up along with the containers. In a production system, these volumes would be mounted onto permanent storage.

Warning: Passwords are stored in plaintext in configuration files. In a production system, passwords should be extracted from a secure keystore at runtime.

Warning: Network connections are not secured. In a production system, connections between services should be TLS-enabled, with a certificate authority (CA) provided.

Warning: The memory use of the containers is only suitable for light demonstration loads. In a production setup, containers need to be given sufficient memory based on memory profiling.

Warning: The versions of the Docker images used in the example may become outdated. In a production system, only the latest patched versions should be used.

29.10.1.2 Network Configuration

In this compose file, define the network that will be used to connect all the running containers:

Listing 1: etc/network-docker-compose.yml

```
# Create with `docker network create monitoring`
# Note that `external: false` will fail the docker-compose execution if the
↪network `monitoring` already exists

version: "3.8"
```

(continues on next page)

(continued from previous page)

```
networks:
  default:
    name: monitoring
    external: false
```

29.10.1.3 Postgres Setup

Using only a single Postgres container, create databases for the sync domain, along with Canton and index databases for each participant. To do this, mount *postgres-init.sql* into the Postgres-initialized directory. Note that in a production environment, passwords must not be inlined inside config.

Listing 2: etc/postgres-docker-compose.yml

```
services:
  postgres:
    image: postgres:14.8-bullseye
    hostname: postgres
    container_name: postgres
    environment:
      - POSTGRES_USER=pguser
      - POSTGRES_PASSWORD=pgpass
    volumes:
      - ../etc/postgres-init.sql:/docker-entrypoint-initdb.d/init.sql
    expose:
      - "5432"
    ports:
      - "5432:5432"
    healthcheck:
      test: "pg_isready -U postgres"
      interval: 5s
      timeout: 5s
      retries: 5
```

Listing 3: etc/postgres-init.sql

```

create database canton1db;
create database index1db;

create database domain0db;

create database canton2db;
create database index2db;

```

29.10.1.4 Synchronization Domain Setup

Run the sync domain with the *-log-profile container* that writes plain text to standard out at debug level.

Listing 4: etc/domain0-docker-compose.yml

```

services:
  domain0:
    image: digitalasset/canton-open-source:2.5.1
    container_name: domain0
    hostname: domain0
    volumes:
      - ./domain0.conf:/canton/etc/domain0.conf
    command: daemon --log-profile container --config etc/domain0.conf
    expose:
      - "10018"
      - "10019"
      - "10020"
    ports:
      - "10018:10018"
      - "10019:10019"
      - "10020:10020"

```

Listing 5: etc/domain0.conf

```

canton {
  domains {
    domain0 {
      storage {
        type = postgres
        config {
          dataSourceClass = "org.postgresql.ds.PGSimpleDataSource"
          properties = {
            databaseName = "domain0db"
            serverName = "postgres"
            portNumber = "5432"
            user = pguser
            password = pgpass
          }
        }
      }
    }
  }
  public-api {

```

(continues on next page)

(continued from previous page)

```

    port = 10018
    address = "0.0.0.0"
  }
  admin-api {
    port = 10019
    address = "0.0.0.0"
  }
}
}
monitoring.metrics.reporters = [{
  type = prometheus
  address = "0.0.0.0"
  port = 10020
}]
}
```

29.10.1.5 Participant Setup

The participant container has two files mapped into it on container creation. The `.conf` file provides details of the sync domain and database locations. An HTTP metrics endpoint is exposed that returns metrics in the [Prometheus Text Based Format](#). By default, participants do not connect to remote sync domains, so a bootstrap script is provided to accomplish that.

Listing 6: `etc/participant1-docker-compose.yml`

```

services:
  participant1:
    image: digitalasset/canton-open-source:2.5.1
    container_name: participant1
    hostname: participant1
    volumes:
      - ./participant1.conf:/canton/etc/participant1.conf
      - ./participant1.bootstrap:/canton/etc/participant1.bootstrap
    command: daemon --log-profile container --config etc/participant1.conf --
    ↪bootstrap etc/participant1.bootstrap
    expose:
      - "10011"
      - "10012"
      - "10013"
    ports:
      - "10011:10011"
      - "10012:10012"
      - "10013:10013"
```

Listing 7: `etc/participant1.bootstrap`

```
participant1.domains.connect(domain0.defaultDomainConnection)
```

Listing 8: `etc/participant1.conf`

```

canton {
  participants {
```

(continues on next page)

(continued from previous page)

```

participant1 {
  storage {
    type = postgres
    config {
      dataSourceClass = "org.postgresql.ds.PGSimpleDataSource"
      properties = {
        databaseName = "cantonldb"
        serverName = "postgres"
        portNumber = "5432"
        user = pguser
        password = pgpass
      }
    }
    ledger-api-jdbc-url = "jdbc:postgresql://postgres:5432/indexldb?
↪user=pguser&password=pgpass"
  }
  ledger-api {
    port = 10011
    address = "0.0.0.0"
  }
  admin-api {
    port = 10012
    address = "0.0.0.0"
  }
}
}
monitoring.metrics.reporters = [{
  type = prometheus
  address = "0.0.0.0"
  port = 10013
}]
remote-domains.domain0 {
  public-api {
    address="domain0"
    port = 10018
  }
  admin-api {
    address = "domain0"
    port = 10019
  }
}
}
}

```

The setup for participant2 is identical, except that the name and ports are changed.

Listing 9: etc/participant2-docker-compose.yml

```

services:
  participant2:
    image: digitalasset/canton-open-source:2.5.1
    container_name: participant2
    hostname: participant2
    volumes:
      - ../participant2.conf:/canton/etc/participant2.conf

```

(continues on next page)

(continued from previous page)

    admin-api {
      address = "domain0"
      port = 10019
    }
  }
}

```

29.10.1.6 Logstash

Docker containers can specify a log driver to automatically export log information from the container to an aggregating service. The example exports log information in GELF, using Logstash as the aggregation point for all GELF streams. You can use Logstash to feed many downstream logging data stores, including Elasticsearch, Loki, and Graylog.

Listing 12: etc/logstash-docker-compose.yml

```

services:
  logstash:
    image: docker.elastic.co/logstash/logstash:8.5.1
    hostname: logstash
    container_name: logstash
    expose:
      - 12201/udp
    volumes:
      - ./pipeline.yml:/usr/share/logstash/config/pipeline.yml
      - ./logstash.yml:/usr/share/logstash/config/logstash.yml
      - ./logstash.conf:/usr/share/logstash/pipeline/logstash.conf
    ports:
      - "12201:12201/udp"

```

Logstash reads the *pipeline.yml* to discover the locations of all pipelines.

Listing 13: etc/pipeline.yml

```

- pipeline.id: main
  path.config: "/usr/share/logstash/pipeline/logstash.conf"

```

The configured pipeline reads GELF-formatted input, then outputs it to an Elasticsearch index prefixed with *logs-* and postfixed with the date.

Listing 14: etc/logstash.conf

```

# Main logstash pipeline

input {
  gelf {
    use_udp => true

```

(continues on next page)

(continued from previous page)

```
    use_tcp => false
    port => 12201
  }
}

filter {}

output {

  elasticsearch {
    hosts => ["http://elasticsearch:9200"]
    index => "logs-%{+YYYY.MM.dd}"
  }
}
```

The default Logstash settings are used, with the HTTP port bound to all host IP addresses.

Listing 15: etc/logstash.yml

```
# For full set of descriptions see
# https://www.elastic.co/guide/en/logstash/current/logstash-settings-file.html

http.host: "0.0.0.0"
```

29.10.1.7 Elasticsearch

Elasticsearch supports running in a clustered configuration with built-in resiliency. The example runs only a single Elasticsearch node.

Listing 16: etc/elasticsearch-docker-compose.yml

```
services:
  elasticsearch:
    image: docker.elastic.co/elasticsearch/elasticsearch:8.5.2
    container_name: elasticsearch
    environment:
      ELASTIC_PASSWORD: elastic
      node.name: elasticsearch
      cluster.name: elasticsearch
      cluster.initial_master_nodes: elasticsearch
      xpack.security.enabled: false
      bootstrap.memory_lock: true
    ulimits:
      memlock:
        soft: -1
        hard: -1
    expose:
      - 9200
    ports:
      - 9200:9200
    healthcheck:
```

(continues on next page)

(continued from previous page)

```
test: "curl -s -I http://localhost:9200 | grep 'HTTP/1.1 200 OK'"
interval: 10s
timeout: 10s
retries: 10
```

29.10.1.8 Kibana

Kibana provides a UI that allows the Elasticsearch log index to be searched.

Listing 17: etc/kibana-docker-compose.yml

```
services:
  kibana:
    image: docker.elastic.co/kibana/kibana:8.5.2
    container_name: kibana
    expose:
      - 5601
    ports:
      - 5601:5601
    environment:
      - SERVERNAME=kibana
      - ELASTICSEARCH_HOSTS=http://elasticsearch:9200
    healthcheck:
      test: "curl -s -I http://localhost:5601 | grep 'HTTP/1.1 302 Found'"
      interval: 10s
      timeout: 10s
      retries: 10
```

You must manually configure a data view to view logs. See [Kibana Log Monitoring](#) for instructions.

29.10.1.9 cAdvisor

cAdvisor exposes container system metrics (CPU, memory, disk, and network) to Prometheus. It also provides a UI to view these metrics.

Listing 18: etc/cadvisor-docker-compose.yml

```
services:
  cadvisor:
    image: gcr.io/cadvisor/cadvisor:v0.45.0
    container_name: cadvisor
    hostname: cadvisor
    privileged: true
    devices:
      - /dev/kmsg:/dev/kmsg
    volumes:
      - /var/run:/var/run:ro
      - /var/run/docker.sock:/var/run/docker.sock:ro
```

(continues on next page)

(continued from previous page)

```

# Although the following two directories are not present on OSX removing
→ them stops cAdvisor working
# Maybe some internal logic checks for the existence of the directory.
- /sys:/sys:ro
- /var/lib/docker/./var/lib/docker:ro
expose:
- 8080
ports:
- "8080:8080"

```

To view container metrics:

1. Navigate to <http://localhost:8080/docker/>.
2. Select a Docker container of interest.

You should now see a UI similar to the one shown.

Usage

Overview

Processes

No processes found

CPU

Total Usage

Prometheus-formatted metrics are available by default at <http://localhost:8080/metrics>.

29.10.1.10 Prometheus

Configure Prometheus with `prometheus.yml` to provide the endpoints from which metric data should be scraped. By default, port 9090 can query the stored metric data.

Listing 19: `etc/prometheus-docker-compose.yml`

```
services:
  prometheus:
    image: prom/prometheus:v2.40.6
    container_name: prometheus
    hostname: prometheus
    volumes:
      - ./prometheus.yml:/etc/prometheus/prometheus.yml
    ports:
      - 9090:9090
```

Listing 20: `etc/prometheus.yml`

```
global:
  scrape_interval: 15s
  scrape_timeout: 10s
  evaluation_interval: 1m

scrape_configs:
  - job_name: canton
    static_configs:
      - targets:
          - domain0:10020
          - participant1:10013
          - participant2:10023

  - job_name: cadvisor
    static_configs:
      - targets:
          - cadvisor:8080

    # Exclude container labels by default
    # curl cadvisor:8080/metrics to see all available labels
    metric_relabel_configs:
      - regex: "container_label_.*"
        action: labeldrop
```

29.10.1.11 Grafana

Grafana is provided with:

- The connection details for the Prometheus metric store
- The username and password required to use the web UI
- The location of any externally provided dashboards
- The actual dashboards

Note that the *Metric Count* dashboard referenced in the `docker-compose.yml` file (`grafana-message-count-dashboard.json`) is not inlined below. The reason is that this is not hand-configured but built via the web UI and then exported. See [Grafana Metric Monitoring](#) for instructions to log into Grafana and display the dashboard.

Listing 21: `etc/grafana-docker-compose.yml`

```
services:
  grafana:
    image: grafana/grafana:9.3.1-ubuntu
    container_name: grafana
    hostname: grafana
    volumes:
      - ./grafana.ini:/etc/grafana/grafana.ini
      - ./grafana-datasources.yml:/etc/grafana/provisioning/datasources/default.
↪yml      - ./grafana-dashboards.yml:/etc/grafana/provisioning/dashboards/default.yml
      - ./grafana-message-count-dashboard.json:/var/lib/grafana/dashboards/
↪grafana-message-count-dashboard.json
    ports:
      - 3000:3000
```

Listing 22: `etc/grafana.ini`

```
instance_name = "docker-compose"

[security]
admin_user = "grafana"
admin_password = "grafana"

[unified_alerting]
enabled = false

[alerting]
enabled = false

[plugins]
plugin_admin_enabled = true
```

Listing 23: `etc/grafana-datasources.yml`

```
---
apiVersion: 1

datasources:
- name: prometheus
```

(continues on next page)

(continued from previous page)

```

type: prometheus
access: proxy
orgId: 1
uid: prometheus
url: http://prometheus:9090
isDefault: true
version: 1
editable: false

```

Listing 24: etc/grafana-dashboards.yml

```

---
apiVersion: 1

providers:
- name: local
  orgId: 1
  folder: ''
  folderUid: default
  type: file
  disableDeletion: true
  updateIntervalSeconds: 30
  allowUiUpdates: true
  options:
    path: /var/lib/grafana/dashboards
    foldersFromFilesStructure: true

```

29.10.1.12 Dependencies

There are startup dependencies between the Docker containers. For example, the sync domain needs to be running before the participant, and the database needs to run before the sync domain.

The *yaml* anchor *x-logging* enabled GELF container logging and is duplicated across the containers where you want to capture logging output. Note that the host address is the host machine, not a network address (on OSX).

Listing 25: etc/dependency-docker-compose.yml

```

x-logging: &logging
driver: gelf
options:
  # Should be able to use "udp://logstash:12201"
  gelf-address: "udp://host.docker.internal:12201"

services:

  logstash:
    depends_on:
      elasticsearch:
        condition: service_healthy

  postgres:
    logging:

```

(continues on next page)

(continued from previous page)

```

    <<: *logging
  depends_on:
    logstash:
      condition: service_started

domain0:
  logging:
    <<: *logging
  depends_on:
    postgres:
      condition: service_healthy
    logstash:
      condition: service_started

participant1:
  logging:
    <<: *logging
  depends_on:
    domain0:
      condition: service_started
    logstash:
      condition: service_started

participant2:
  logging:
    <<: *logging
  depends_on:
    domain0:
      condition: service_started
    logstash:
      condition: service_started

kibana:
  depends_on:
    elasticsearch:
      condition: service_healthy

grafana:
  depends_on:
    prometheus:
      condition: service_started

```

29.10.1.13 Docker Images

The Docker images need to be pulled down before starting the network:

```

digitalasset/canton-open-source:2.5.1
docker.elastic.co/elasticsearch/elasticsearch:8.5.2
docker.elastic.co/kibana/kibana:8.5.2
docker.elastic.co/logstash/logstash:8.5.1
gcr.io/cadvisor/cadvisor:v0.45.0
grafana/grafana:9.3.1-ubuntu
postgres:14.8-bullseye
prom/prometheus:v2.40.6

```

29.10.1.14 Running Docker Compose

Since running `docker compose` with all the compose files shown above creates a long command line, a helper script `dc.sh` is used.

A minimum of **12GB** of memory is recommended for Docker. To verify that Docker is not running short of memory, run `docker stats` and ensure the total `MEM%` is not too high.

Listing 26: `dc.sh`

```
#!/bin/bash

if [ $# -eq 0 ];then
    echo "Usage: $0 <docker compose command>"
    echo "Use '$0 up --force-recreate --renew-anon-volumes' to re-create network"
    exit 1
fi

set -x

docker compose \
    -p monitoring \
    -f etc/network-docker-compose.yml \
    -f etc/cadvisor-docker-compose.yml \
    -f etc/elasticsearch-docker-compose.yml \
    -f etc/logstash-docker-compose.yml \
    -f etc/postgres-docker-compose.yml \
    -f etc/domain0-docker-compose.yml \
    -f etc/participant1-docker-compose.yml \
    -f etc/participant2-docker-compose.yml \
    -f etc/kibana-docker-compose.yml \
    -f etc/prometheus-docker-compose.yml \
    -f etc/grafana-docker-compose.yml \
    -f etc/dependency-docker-compose.yml \
    $*
```

Useful commands

```
./dc.sh up -d          # Spins up the network and runs it in the background
./dc.sh ps             # Shows the running containers
./dc.sh stop           # Stops the containers
./dc.sh start          # Starts the containers
./dc.sh down           # Stops and tears down the network, removing any created
↳ containers
```

29.10.2 Connecting to Nodes

To interact with the running network, a Canton console can be used with a remote configuration. For example:

```
bin/canton -c etc/remote-participant1.conf
```

29.10.2.1 Remote Configurations

Listing 27: etc/remote-domain0.conf

```
canton.remote-domains.domain0 {  
  admin-api {  
    address="0.0.0.0"  
    port="10019"  
  }  
  public-api {  
    address="0.0.0.0"  
    port="10018"  
  }  
}
```

Listing 28: etc/remote-participant1.conf

```
canton {  
  
  features.enable-testing-commands = yes // Needed for ledger-api  
  
  remote-participants.participant1 {  
    ledger-api {  
      address="0.0.0.0"  
      port="10011"  
    }  
    admin-api {  
      address="0.0.0.0"  
      port="10012"  
    }  
  }  
}
```

Listing 29: etc/remote-participant2.conf

```
canton {  
  
  features.enable-testing-commands = yes // Needed for ledger-api  
  
  remote-participants.participant2 {  
    ledger-api {  
      address="0.0.0.0"  
      port="10021"  
    }  
    admin-api {
```

(continues on next page)

(continued from previous page)

```

    address="0.0.0.0"
    port="10022"
  }
}
}

```

29.10.2.2 Getting Started

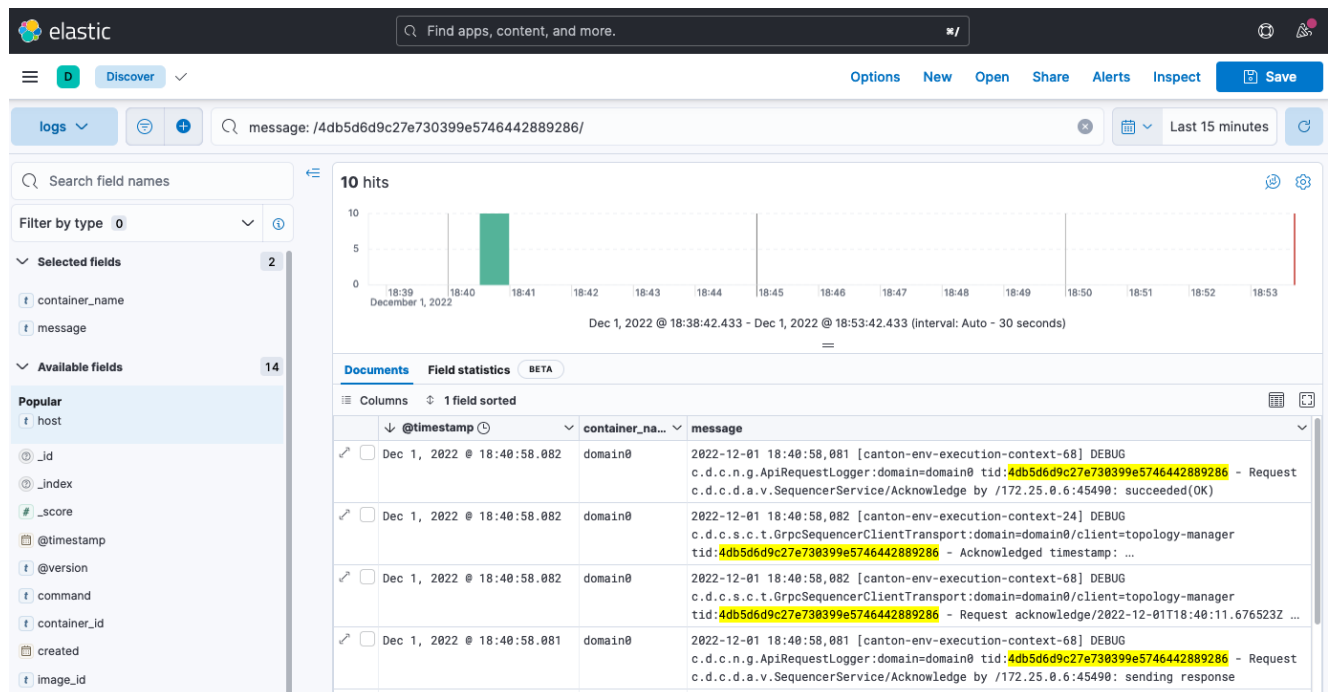

Using the previous scripts, you can follow the examples provided in the [Getting Started](#) guide.

29.10.3 Kibana Log Monitoring

When Kibana is started for the first time, you must set up a data view to allow view the log data:

1. Navigate to <http://localhost:5601/>.
2. Click **Explore on my own**.
3. From the menu select **Analytics > Discover**.
4. Click **Create data view**.
5. Save a data view with the following properties:
 Name: *Logs*
 Index pattern: *logs-**
 Timestamp field: *@timestamp*

You should now see a UI similar to the one shown here:

In the Kibana interface, you can:

- Create a view based on selected fields
- View log messages by logging timestamp
- Filter by field value

Search for text
Query using either KSQL or Lucene query languages

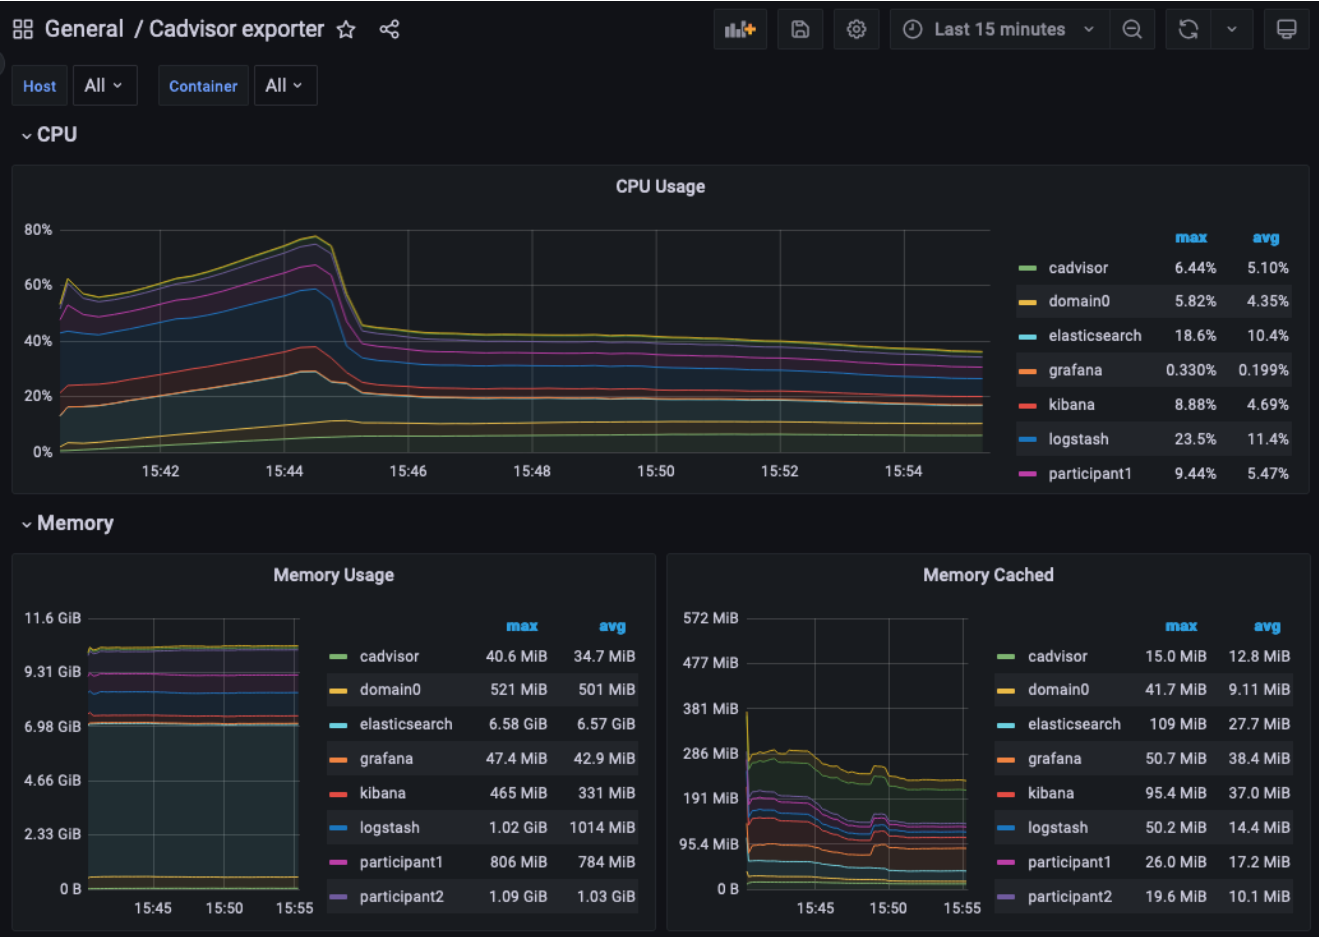

For more details, see the Kibana documentation. Note that querying based on plain text for a wide time window likely results in poor UI performance. See [Logging Improvements](#) for ideas to improve it.

29.10.4 Grafana Metric Monitoring

You can log into the Grafana UI and set up a dashboard. The example imports a [GrafanaLabs community dashboard](#) that has graphs for cAdvisor metrics. The [cAdvisor Export dashboard](#) imported below has an ID of **14282**.

- 1. Navigate to <http://localhost:3000/login>.
- 2. Enter the username/password: *grafana/grafana*.
- 3. In the side border, select **Dashboards** and then **Import**.
- 4. Enter the dashboard ID 14282 and click **Load**.
- 5. On the screen, select **Prometheus** as the data source and click **Import**.

You should see a container system metrics dashboard similar to the one shown here:

See the [Grafana documentation](#) for how to configure dashboards. For information about which metrics are available, see the Metrics documentation in the Monitoring section of this user manual.

29.10.5 Monitoring Choices

This section documents the reasoning behind the technology used in the example monitoring setup.

29.10.5.1 Use Docker Log Drivers

Reasons:

- Most Docker containers can be configured to log all debug output to stdout.
- Containers can be run as supplied.
- No additional dockerfile layers need to be added to install and start log scrapers.
- There is no need to worry about local file naming, log rotation, and so on.

29.10.5.2 Use GELF Docker Log Driver

Reasons:

- It is shipped with Docker.
- It has a decodable JSON payload.
- It does not have the size limitations of syslog.
- A UDP listener can be used to debug problems.

29.10.5.3 Use Logstash

Reasons:

- It is a lightweight way to bridge the GELF output provided by the containers into Elasticsearch.
- It has a simple conceptual model (pipelines consisting of input/filter/output plugins).
- It has a large ecosystem of input/filter and output plugins.
- It externalizes the logic for mapping container logging output to a structures/ECS format.
- It can be run with *stdin/stdout* input/output plugins for use with testing.
- It can be used to feed Elasticsearch, Loki, or Graylog.
- It has support for the Elastic Common Schema (ECS) if needed.

29.10.5.4 Use Elasticsearch/Kibana

Reasons:

- Using Logstash with Elasticsearch and Kibana, the ELK stack, is a mature way to set up a logging infrastructure.
- Good defaults for these products allow a basic setup to be started with almost zero configuration.
- The ELK setup acts as a good baseline as compared to other options such as Loki or Graylog.

29.10.5.5 Use Prometheus/Grafana

Reasons:

Prometheus defines and uses the OpenTelemetry reference file format.
Exposing metrics via an HTTP endpoint allows easy direct inspection of metric values.
The Prometheus approach of pulling metrics from the underlying system means that the running containers do not need infrastructure to store and push metric data.
Grafana works very well with Prometheus.

29.10.6 Logging Improvements

This version of the example only has the logging structure provided via GELF. It is possible to improve this by:

Extracting data from the underlying containers as a JSON stream.
Mapping fields in this JSON data onto the ECS so that the same name is used for commonly used field values (for example, log level).
Configuring Elasticsearch with a schema that allows certain fields to be quickly filtered (for example, log level).

29.11 Glossary

29.11.1 cAdvisor

Container Advisor (cAdvisor) provides an overview of CPU, memory, disk, and network utilization for each of the Docker containers. It works by querying the [Docker Engine API](#) to get these statistics for each container. This lets you avoid layering the containers with a utility to perform these functions.

<https://github.com/google/cadvisor>

29.11.2 Docker Log Driver

Docker containers can be configured with a log driver that allows log output to be exported from the Docker container. Using log drivers to export logging information makes running another process on the Docker container for this unnecessary.

<https://docs.docker.com/config/containers/logging/configure/>

29.11.3 Docker Plugins

A Docker plugin is a way to extend Docker (for example, by adding a log driver).

<https://docs.docker.com/engine/extend/>

29.11.4 ECS

The Elastic Common Schema (ECS) defines a naming convention for fields used in Elasticsearch. For example, use `@timestamp` for timestamp.

<https://www.elastic.co/guide/en/ecs/current/ecs-field-reference.html>

29.11.5 Elasticsearch

Elasticsearch is a technology that allows JSON documents to be stored, indexed, and searched in near real time. It can be configured as a cluster with built-in resiliency.

<https://www.elastic.co/guide/en/elasticsearch/reference/8.5/index.html>

29.11.6 ELK

The ELK stack is an established way to enable capturing, indexing, and displaying log data.

<https://www.elastic.co/what-is/elk-stack>

29.11.7 GELF

The Graylog extended logging format (GELF) improves on syslog logging by providing structured messages that are not size-limited. GELF is one of the built-in logging drivers supported by Docker. The message format is compressed JSON.

<https://docs.graylog.org/docs/gelf>

29.11.8 Grafana

Grafana provides a web UI that allows the construction of dashboards showing metric data. This data can be queried against a Prometheus metric store.

<https://grafana.com/grafana/>

29.11.9 Graylog

Unlike Elasticsearch, Graylog is not a general-purpose indexing, analytics, and search tool. It is designed specifically for log data. This provides a simpler, more focused option with better defaults for logging.

<https://www.graylog.org/about/>

29.11.10 Logstash

Logstash is a service that allows a series of pipelines to be configured that read, filter, and manipulate data before writing it out. It has support for a multitude of input, filter, and output types. The GELF input reader and Elasticsearch output writer are of particular interest.

<https://www.elastic.co/guide/en/logstash/current/introduction.html>

29.11.11 Loki

Loki is a log aggregation system designed to store and query logs from all your applications and infrastructure. It displays log information inside Grafana, allowing a single UI to be used for both metric data and logs.

<https://grafana.com/oss/loki/>

29.11.12 Loki Log Driver

The Loki log driver is a Loki client that allows log information to be shipped from a Docker log file, similar to other log drivers. The message format is gRPC protobuf.

<https://grafana.com/docs/loki/latest/clients/docker-driver/>

29.11.13 MinIO

AWS S3 Compatible Storage (used by Loki).

<https://min.io/product/s3-compatibility>

29.11.14 OpenTelemetry

OpenTelemetry is an organization that works to standardize observability (an umbrella term that includes logging, metrics, and tracing).

<https://opentelemetry.io/>

29.11.15 Prometheus

Prometheus can be configured to scrape metric data from many endpoints. This metric data can then be queried by metric visualization tools such as Grafana.

<https://prometheus.io/>

29.11.16 Syslog

Syslog is a standard for logging messages that has been around since the 1980s. Syslog is one of the built-in logging drivers supported by Docker.

<https://en.wikipedia.org/wiki/Syslog>

Chapter 30

PQS

30.1 Introduction

PQS (Participant Query Store) is a feature that makes the ledger available to be queried by SQL. This enables users to query the state and history of the ledger, while minimizing the demand on the participant node.

Note: The term Operational Data Store (ODS) refers to a database that mirrors the Daml ledger and allows for efficient querying. The PQS feature is an ODS for the participant.node.

30.1.1 Audience

This documentation provides guidance on what PQS achieves, how to use it, and its operation and limitations. The following types of users are likely to find PQS useful:

Application developers: to query the ledger to display information to users, integrate or carry out automated business processes, and debugging.

Business analysts: to access and analyze ledger data with ad-hoc investigations to understand operational usage.

Support analysts: to diagnose any problems on a live system, when sophisticated inspection of the ledger is required.

Application operators: to take a snapshot of the ledger, either with or without history in order to analyse and investigate.

Report analysts: to provide access to ledger data information for analysis and aggregation with standard reporting tools, on a historical or real-time basis.

30.1.2 Purpose

PQS provides powerful and scaleable read access for a participant by exposing all data via SQL - leveraging existing tools and knowledge.

The participant's primary role is to submit and propagate transactions in the network, which requires interaction to submit commands. PQS works in this domain to monitor transactions on a streaming basis, maintain history and state based on these events, and makes the resultant data available for users to query. It allows independent scaling of the read loads, depending on the capacity required.

30.1.3 Operational Architecture

PQS is a service that operates within the trusted core infrastructure of a participant. It can be configured via command line arguments, environment variables and configuration files. It is intended as a long-running process and is resilient to network outages. It is also designed to be idempotent (or crash tolerant) so that it can be restarted safely at any time. It does not write to the ledger; it is a passive consumer of data from a Canton participant. PQS focuses on providing a powerful and scaleable read pipeline - as per the [CQRS](#) design pattern.

The following diagram shows that PQS initiates connections to both the participant and the datatore: (arrows indicate the direction of connection)

Connection Flow

Similarly, from the perspective of data-flow:

Data Flow

Expanding the application node from the above, you can imagine many potential architectures, including:

App Connection Flow

30.1.4 Key Feature Summary

PQS enables the following key capabilities:

To make the Daml ledger queryable via SQL.

Allow querying on a point-in-time or latest-available basis.

Filter the scope by Daml party and contract template.

Embed an API within the database to allow consumers to easily access the ledger data by:

- Using familiar Daml identifiers (eg. `mypackage:My.Module:MyTemplate`) instead of PostgreSQL approximations.
- Using SQL to perform familiar aggregations, transformations and joins.
- Creating custom indexes to optimize queries.
- Facilitating access to both state (contracts) and audit trail (events) perspectives.

Crash-tolerance so it can be restarted safely.

30.2 Getting Started

30.2.1 Pre-requisites

To run PQS you need the following:

- PostgreSQL version 12-16.
- Daml Sandbox or participant.as the source of ledger data.
- Any access tokens or TLS certificates required by the above.
- PQS .jar or Docker image

30.2.2 Running PQS

Exploring commands and parameters is easiest via the `--help` (and `--help-verbose`) arguments: For example, if you are running a downloaded .jar file:

```
$ ./scribe.jar --help
Usage: scribe COMMAND

An efficient ledger data exporting tool

Options:
  -h, --help            Print help information and quit
  -H, --help-verbose    Print help information with extra details and quit
  -v, --version          Print version information and quit

Commands:
  pipeline      Initiate continuous ledger data export
  datastore     Perform operations supporting a certified data store

Run 'scribe COMMAND --help[-verbose]' for more information on a command.
```

Or similarly, using Docker:

```
$ docker run -it digitalasset-docker.jfrog.io/participant-query-store:0.5.0 --help
Picked up JAVA_TOOL_OPTIONS: -javaagent:/open-telemetry.jar
Usage: scribe COMMAND

An efficient ledger data exporting tool

Commands:
  pipeline      Initiate continuous ledger data export
  datastore     Perform operations supporting a certified data store

Run 'scribe COMMAND --help[-verbose]' for more information on a command.
```

30.2.2.1 Daml Platform Support

From version 0.5.0 PQS is built and tested against multiple Daml SDK targets. Each Daml SDK target generates its own `.jar` file. These binaries are present in the published participant-query-store docker images. The container defaults to the lowest targeted Daml SDK. To run PQS against a newer target, you must set the container's `workdir` at runtime to the desired Daml SDK target.

The supported targets are:

```
/daml2 << default
/daml3.2
/daml3.3
```

Please note that the preceeding `/` is required as the target is the path to the `scribe.jar` file.

An example of the default Daml SDK target:

```
$ docker run -it digitalasset-docker.jfrog.io/participant-query-store:0.5.0 --
↪version
Picked up JAVA_TOOL_OPTIONS: -javaagent:/open-telemetry.jar
scribe, version: v0.5.0
daml-sdk.version: 2.9.5
postgres-document.schema: 021
```

An example of selecting the `/daml3.2` target:

```
docker run -it --workdir /daml3.2 digitalasset-docker.jfrog.io/participant-query-
↪store:0.5.0 --version
Picked up JAVA_TOOL_OPTIONS: -javaagent:/open-telemetry.jar
scribe, version: v0.5.0
daml-sdk.version: 3.2.0-snapshot.20241106.13400.0.vad854047
postgres-document.schema: 021
```

30.2.2.2 Preparing the Database

Start by investigating the database schema that PQS creates, using the `datastore` command that is used for administrative operations:

```
$ ./scribe.jar datastore postgres-document schema show
[...]
/*****
 * generated by scribe, version: [...]
 *****/
-- tables
create table [...]
```

A database administrator can now choose to create the database and apply the produced DDL, or leave it to the `pipeline` command to do this on an ongoing idempotent basis.

30.2.2.3 Running the Pipeline

The following command connects to a non-auth ledger and replicates the latest state of the ledger (excluding prior-history) from the perspective of the supplied Daml party. It uses the ledger source and supplied database, though these values can be omitted as they are all defaults:

```
$ ./scribe.jar pipeline ledger postgres-document \
  --pipeline-filter-parties☐
↪Alice::12209942561b94adc057995f9ffca5a0b974953e72ba25e0eb158e05c801149639b9 \
  --pipeline-ledger-start Latest \
  --target-postgres-host localhost \
  --target-postgres-port 5432 \
  --target-postgres-database postgres \
  --source-ledger-port 6865 \
  --source-ledger-host localhost
18:27:26.799 I [zio-fiber-64] com.digitalasset.scribe.appversion.package:11☐
↪scribe, version: v...
18:27:27.159 I [zio-fiber-68] com.digitalasset.scribe.configuration.package:40☐
↪Applied configuration:
[...]
```

```
18:27:28.714 I [zio-fiber-67] com.digitalasset.scribe.postgres.document.
↪DocumentPostgres.Service:36 Applying schema
18:27:28.805 I [zio-fiber-67] com.digitalasset.scribe.postgres.document.
↪DocumentPostgres.Service:39 Schema applied
18:27:28.863 I [zio-fiber-0] com.digitalasset.scribe.pipeline.pipeline.Impl:29☐
↪Starting pipeline on behalf of 'Alice::...'
18:27:29.043 I [zio-fiber-0] com.digitalasset.scribe.pipeline.pipeline.Impl:57☐
↪Last checkpoint is absent. Seeding from ACS before processing transactions with☐
↪starting offset '00000000000000000008'
18:27:29.063 I [zio-fiber-938] com.digitalasset.zio.daml.Ledger.Impl:191 Contract☐
↪filter inclusive of 4 templates and 0 interfaces
18:27:29.120 I [zio-fiber-0] com.digitalasset.scribe.pipeline.pipeline.Impl:74☐
↪Continuing from offset 'GENESIS' and index '0' until offset 'INFINITY'
18:27:29.159 I [zio-fiber-967] com.digitalasset.zio.daml.Ledger.Impl:191 Contract☐
↪filter inclusive of 4 templates and 0 interfaces
[...]
```

Note: The above command continues to run until terminated. You can terminate it with `Ctrl-C` at any time.

30.2.2.4 Auth

If you are running PQS against a participant that has auth, you must provide some credentials. For example:

```
$ ./scribe.jar pipeline ledger postgres-document \
  --source-ledger-auth OAuth \
  --pipeline-oauth-clientid my_client_id \
  --pipeline-oauth-clientsecret deadbeef \
  --pipeline-oauth-cafile ca.crt \
  --pipeline-oauth-endpoint https://my-auth-server/token
```

For more information see the [Authentication](#) section.

30.3 Database

PQS supports a single datastore format known as `postgres-document`. This uses PostgreSQL to store the data in a document-oriented (schemaless) way, making extensive use of JSONB.

30.3.1 Ledger Source

To understand how PQS stores data, you need to understand the ledger data model. In simple terms, the Daml ledger is composed of a sequence of transactions, which contain events. Events can be:

Creates: creation of contracts / interface views.

Exercise: of a choice of contracts / interface views.

Archive: end of the lifetime of contracts / interface views.

Warning: When defining the scope of ledger data being stored, it is important to understand the implications of the data source and the filters applied. The data source and filters determine the data that is available to the [Read API](#) functions, and this cannot be changed. Since a change in scope will result in a change to the breadth of data being stored, a re-seed is required to widen or narrow the scope of the data. The only exception to this is where you widen the scope into a new area (eg. new templates new parties) that you know has no historical data, in which case a re-seed is not required. Or, operators may also use the [reset](#) function to roll-back the datastore to a prior state where this was true.

30.3.2 Transaction Data Source

PQS can run in two modes as specified by the `--pipeline-datasource` configuration. The following table shows the differences between the two modes, in terms of data availability via the respective [Read API](#) functions :

Data / Mode	TransactionStream	TransactionTreeStream
<code>creates()</code> contracts	✓	✓
<code>exercises()</code> contracts		✓
<code>archives()</code> contracts	✓	✓
<code>creates()</code> interfaces	✓	
<code>exercises()</code> interfaces		✓
<code>archives()</code> interfaces	✓	
Transient (create-archive in a transaction)		✓
Stakeholders	✓	✓
Note:		
Default	✓	
Data size	Smaller	Larger

30.3.3 PostgreSQL Schema

The PostgreSQL schema is designed to be generic and not tied to any specific Daml model. This is achieved by a fixed schema that relates to the general ledger model but uses a documented-oriented approach (JSONB) to store the data whose schema lies in the Daml models.

Warning: Any database artifact starting with an underscore character (`_`) is explicitly denoted an internal implementation, subject to change, and should not be relied upon. Since every table is prefixed this way, they change in the future - for example as a result of future functional and performance enhancements.

Ledger data consumers should interact with the database via the [Read API](#), which provides a stable supported interface. Database Administrators who wish to have a deeper understanding of the schema specifics, in order to understand it's operational characteristics, can easily inspect the schema using the command:

```
$ ./scribe.jar datastore postgres-document schema show
[...]
```

30.3.3.1 Objectives

Overall, the objectives of the schema design are to facilitate:

Scaleable writes: high-throughput and efficient to free up as much capacity for useful work (reads) as possible.

Scaleable reads: queries can able to be parallelized, and do not become blocked behind writes. They produce sensible query plans that do not result in unnecessary table scans.

Ease of use: readers can use familiar tools and techniques to query the database, without needing to understand the specifics of the schema design. Instead, they can use simple entry points that provide access to data in familiar ledger terms: active contracts, creates, exercises, archives, offsets, etc. Readers do not need to worry about an offset-based model for point-in-time snapshot isolation.

Read consistency: readers can achieve the level of consistency that they require, including consistency with other queries they are conducting.

Crash tolerance: the schema is designed to be simple and ensure recovery from any kind of crash, taking a pessimistic view of what races may occur, however unlikely.

Static schema: the schema is designed to be static and not require any changes to the schema as the ledger evolves, to the extent possible. Note: discovering adding new templates during normal operation does currently require additional table partitions to be created.

30.3.3.2 Design

To facilitate these objectives, the following design approaches have been used:

Concurrent append-only writes: ledger transactions are written with significant parallelism without contention, ensuring that writes can be high-throughput and unconstrained by latency.

Bulk batching: using `COPY` (not `INSERT`) to deliver large batches of data efficiently.

Offset indexed: all data is appropriately indexed by offset to provide efficient access to slice the result by offset. `BRIN` indexes are used to ensure contiguity of data that is often accessed together.

Implicit offset: readers can opt for queries with implicit offset, meaning they can ignore the role of offset in their queries but still receive a stable view of the ledger data. We seek to provide a similar experience to PostgreSQL's MVCC, where users receive consistency benefits without needing to understand the underlying implementation.

Idempotent: PQS is designed to be restarted safely at any time. All state is maintained in the datastore.

Watermarks: a single thread maintains a watermark denoting the most recent contiguous transaction - representing the offset of the most recent consistent ledger transaction. In addition, the watermark processes the `archive` mutation on any archived contracts or interface views, in a batch. This reintroduces data consistency without needing readers to perform complex query paths. This efficiently resolves the uncertainty created by the parallel writes.

Schemaless content: content defined in Daml templates uses the JSONB datatype to store the data. This allows for a schemaless approach and can store any Daml model without needing to change the schema, other than custom JSONB indexes.

30.4 Configuration

Several items need to be configured to suit your environment and requirements. This section provides an overview of common configuration options that you should consider for your deployment:

30.4.1 PQS Configuration

PQS ascertains its configuration from:

- command-line arguments
- environment variables
- HOCON configuration files (`--config` argument)

Note: Consult the command `./scribe.jar pipeline --help-verbose` for further information on individual configuration items, and the conventions used to specify them in the above forms.

Complex configurations may benefit from using a HOCON configuration file, for example:

```
{
  health.port = 8080

  logger {
    # level = "Debug"
```

(continues on next page)

(continued from previous page)

```

    format = "Plain"
    pattern = "Plain"
  }

  pipeline {
    datasource = "TransactionStream"

    filter {
      parties = "*"
      metadata = "!*"
      contracts = "*"
    }

    ledger {
      start = "Latest"
      stop = "Never"
    }
  }

  source {
    ledger {
      host = "canton"
      port = 10011
    }
  }

  target {
    postgres {
      host = "postgres"
      port = 5432
      username = "postgres"
      database = "postgres"
      maxConnections = 16
    }
  }
  schema.autoApply = true
}

```

Note: For more information on logging configuration, see the dedicated [Logging](#) section.

30.4.1.1 Applying Configuration Changes

PQS sets its configuration at startup. It does not perform dynamic configuration updates, so making a configuration change (such as adding a new party, new template, or new interface) requires a restart.

Warning: PQS will not go back in time and recover history - but only move forward by consuming new transactions it has not previously seen. It is important that scope only be expanded when it is known to have no prior history, at the point in time that PQS was stopped. Otherwise, a re-seed operation will be required to reinitialize from a empty datastore, will be required.

30.4.2 Contract Filters

`--pipeline-filter-contracts` specifies an inclusion filter expression to determine the Daml templates, interface views and choices include. A filter expression is a simple wildcard inclusion (*) with basic boolean logic (& ! | ()), where whitespace is ignored. For example:

```
*: everything (default)
pkg: *: everything in this package
pkg:a.b.c.Bar: just this one fully qualified name for template Bar
a.b.c.*: all members of the a.b.c namespace
* & !pkg:a.b.c.Bar: everything except this one fully qualified name
(a.b.c.Foo | a.b.c.Bar): these two fully qualified names
(a.b.c.* & !(a.b.c.Foo | a.b.c.Bar) | g.e.f.Baz): everything in a.b.c except
for Foo and Bar, and also include g.e.f.Baz
a.b.c.Foo & a.b.c.Bar: error (the identifier can't be both)
```

Note: There are further conditions placed upon the filtering of templates and interfaces to avoid potential ambiguity. It is required to include any filter for:

```
All Interface Views of included Templates
All Templates of included Interface Views
```

30.4.3 Party Filtering

Similarly, the `--pipeline-filter-parties` option specifies an inclusion filter expression to determine which parties to supply data for. For example:

```
*: everything (default)
Alice::* | Bob::*: any party with an Alice or Bob hint
Alice::122055fc4b190e3fff438587b699495a4b6388e911e2305f7e013af160f49a76080ab:
just this one party
* & !Alice::*: all parties except those with an Alice hint
Alice* | Bob* | (Charlie* & !(Participant3::*)): Alice and Bob parties, as well
as Charlie except Charlie3
```

When the ledger requires authentication, this filter applies within the scope of parties for which PQS's Ledger API user has access. Naturally, the `--pipeline-filter-parties` cannot be used to access data for parties for which the user is not authorized.

30.4.4 Java Virtual Machine (JVM) Configuration

JVM configuration is important to ensure that PQS has enough resources to run efficiently. At minimum the following should be considered for any realistic deployment:

```
-XX:+AlwaysPreTouch
-XX:-UseAdaptiveSizePolicy

## containers:
-XX:InitialRAMPercentage=75.0
-XX:MaxRAMPercentage=75.0
```

(continues on next page)

(continued from previous page)

```
## host/vm:
-Xms4g
-Xmx4g
```

In scenarios of resource-constraint, an out-of-memory error may occur. To diagnose this, a heap-dump will need to be collected for analysis, by adding the following JVM parameters:

```
-XX:+HeapDumpOnOutOfMemoryError
-XX:HeapDumpPath=/path/to/heap.dump
```

If you wish to have more detailed logging for diagnosis, you can adjust the `--logger-level` parameter to `Debug` or `Trace`. However, be aware that this will generate a lot of log output and may negatively impact performance. Therefore it is recommended you de-scope particularly verbose components (such as `Netty`) to `Info` level. This can be done by adding the following arguments:

```
--logger-level=Debug
--logger-mappings-io.netty=Info
--logger-mappings-io.grpc.netty=Info
```

Setting the Ledger API queue length is a trade-off between memory usage and performance. The default value is 128, and can be increased to deliver more stable performance, at the cost of requiring additional memory. Note that the buffer will consume memory equal to the size of transactions in the rolling window of the buffer size:

```
--source-ledger-buffersize=1024
```

30.4.5 PostgreSQL Configuration

Users should at least consider the following PostgreSQL config items which are relevant to the workloads it will be expected to satisfy:

```
## postgresql.conf:
[autovacuum_*] (https://www.postgresql.org/docs/16/runtime-config-autovacuum.html
↳ #RUNTIME-CONFIG-AUTOVACUUM)
[maintenance_work_mem] (https://www.postgresql.org/docs/16/runtime-config-resource.html#GUC-MAINTENANCE-WORK-MEM)
[checkpoint_*] (https://www.postgresql.org/docs/16/runtime-config-wal.html#RUNTIME-CONFIG-WAL-CHECKPOINTS)
[*_wal_size] (https://www.postgresql.org/docs/16/runtime-config-wal.html#GUC-MAX-WAL-SIZE)
[bgwriter_*] (https://www.postgresql.org/docs/16/runtime-config-resource.html#RUNTIME-CONFIG-RESOURCE-BACKGROUND-WRITER)
```

In cases where high performance is required, a DBA will need to tune PostgreSQL for the intended workload and infrastructure.

30.4.6 PostgreSQL Users

To secure the PostgreSQL database, you should consider the rights granted to various users that connect to the database. At minimum the following user categories should be considered with their respective [DDL/ACL privileges](#):

Administraton: Provides a way for Database Administrators to perform any action on the database - SUPERUSER

Processing: The user that PQS process connects to the database as - SELECT, INSERT, UPDATE, DELETE

Querying: Data consumers that connect to the database to read the ledger data - SELECT

Redaction: Any users that needs to perform redaction operations - SELECT, UPDATE

Pruning: Users perform pruning operations - SELECT, UPDATE, DELETE

Indexing: Users that maintain JSONB indexes - CREATE

30.4.7 Host Infrastructure

The following are the minimum requirements for the host operating system running any kind of production workload, and should be seen as a starting point for determining the appropriate resources required by a particular workload:

PQS host:

Memory: 4GB

CPU: 4 cores

PostgreSQL:

Memory: 8GB

CPU: 8 cores

30.4.8 Host Environment

PQS requires write access to the `/tmp` directory in order temporarily cache Daml packages. The size of this cache is proportional to the size of all Daml packages observable on the ledger. It is an ephemeral cache - so it does not need to persist beyond a single execution. Containerized environments should configure a disk-based mount, as it is not important for overall performance.

30.4.9 Testing

Of course all of these settings need to be independently assessed and tuned. Users should establish performance testing and benchmarking environment in order to validate the performance of PQS on a given workload. It should be noted that the following variables are extremely relevant to overall PQS performance characteristics:

Network latency

Ledger transaction throughput

Ledger transaction sizes

Contract data sizes

Changing any of these variables requires re-testing to ensure that the impact on system performance is understood, and within acceptable tollerances.

As a reference you may want to consult the *Performance Benchmarking* section of the documentation, for an example of one such performance benchmark. This may give you a sense of the performance characteristics, and allow you to adapt it into something that matches your workloads.

30.5 Resilience

PQS is designed to operate as a long-running process which uses these principles to enhance availability:

Redundancy involves running multiple instances of PQS in parallel to ensure that the system remains available even if one instance fails.

Retry involves healing from transient and recoverable failures without shutting down the process or requiring operator intervention.

Recovery entails reconciling the current state of the ledger with already exported data in the datastore after a cold start, and continuing from the latest checkpoint.

30.5.1 High Availability

Multiple isolated instances of PQS can be instantiated without any cross-dependency. This allows for an active-active high availability clustering model. Please note that different instances might not be at the same offset due to different processing rates and general network non-determinism. PQS's Read API provides capabilities to deal with this 'eventual consistency' model, to ensure that readers have at least 'repeatable read' consistency. See `validate_offset_exists()` in the [Read API](#) for more details.

30.5.2 Retries

PQS's `pipeline` command is a unidirectional streaming process that heavily relies on the availability of its `source` and `target` dependencies. When PQS encounters an error, it attempts to recover by restarting its internal engine, if the error is designated as recoverable:

`gRPC` (white-listed; retries if):

- CANCELLED
- DEADLINE_EXCEEDED
- NOT_FOUND
- PERMISSION_DENIED
- RESOURCE_EXHAUSTED
- FAILED_PRECONDITION
- ABORTED
- INTERNAL
- UNAVAILABLE

- DATA_LOSS
 - UNAUTHENTICATED
- JDBC (black-listed; retries unless):**
- INVALID_PARAMETER_TYPE
 - PROTOCOL_VIOLATION
 - NOT_IMPLEMENTED
 - INVALID_PARAMETER_VALUE
 - SYNTAX_ERROR
 - UNDEFINED_COLUMN
 - UNDEFINED_OBJECT
 - UNDEFINED_TABLE
 - UNDEFINED_FUNCTION
 - NUMERIC_CONSTANT_OUT_OF_RANGE
 - NUMERIC_VALUE_OUT_OF_RANGE
 - DATA_TYPE_MISMATCH
 - INVALID_NAME
 - CANNOT_COERCE
 - UNEXPECTED_ERROR

30.5.2.1 Configuration

The following configuration options are available to control the retry behavior of PQS:

```
$ ./scribe.jar pipeline --help
[...]
```

<code>--retry-backoff-base</code> string	Base time (ISO 8601) for backoff
<code>↪retry strategy</code> (default: PT1S)	
<code>--retry-backoff-cap</code> string	Max duration (ISO 8601) between
<code>↪attempts</code> (default: PT1M)	
<code>--retry-backoff-factor</code> double	Factor for backoff retry strategy
<code>↪(default: 2.0)</code>	
<code>--retry-counter-attempts</code> int	Max attempts before giving up
<code>↪(optional)</code>	
<code>--retry-counter-reset</code> string	Reset retry counters after period
<code>↪(ISO 8601) of stability</code> (default: PT10M)	
<code>--retry-counter-duration</code> string	Time limit (ISO 8601) before giving
<code>↪up</code> (optional)	
<code>[...]</code>	

Configuring `--retry-backoff-*` settings control periodicity of retries and the maximum duration between attempts.

Configuring `--retry-counter-attempts` and `--retry-counter-duration` controls the maximum *instability* tolerance before shutting down.

Configuring `--retry-counter-reset` controls the period of *stability* after which the retry counters are reset across the board.

30.5.2.2 Logging

```
## Irrelevant log lines omitted
$ scribe.jar pipeline ledger postgres-document \
  --pipeline-ledger-start Oldest --pipeline-ledger-stop Never \
  --retry-backoff-base=PT10S --retry-counter-duration=PT10M --retry-counter-

```

30.5.2.3 Metrics

The following metrics are available to monitor stability of PQS's dependencies. See the [observability](#) section for more details on general observability:

```
## TYPE app_restarts_total counter
## HELP app_restarts_total Number of total app restarts due to recoverable errors
app_restarts_total{exception="Recoverable GRPC exception."} 5.0

## TYPE grpc_up gauge
## HELP grpc_up Grpc channel is up
grpc_up{} 1.0

## TYPE jdbc_conn_pool_up gauge
## HELP jdbc_conn_pool_up JDBC connection pool is up
jdbc_conn_pool_up{} 1.0
```

30.5.2.4 Retry Counters Reset

If PQS encounters network unavailability it starts incrementing retry counters with each attempt. These counters are reset only after a period of stability, as defined by `--retry-counter-reset`. As such, during the prolonged periods of intermittent failures that alternate with brief periods of operating normally, PQS keeps maintaining a cautious stance on assumptions regarding the stability of the overall system. This can be illustrated with an example below:

```
## --retry-counter-reset=PT5M

time -->          1:00              5:00              10:00
           v                        v                        v
operation:  ===xx=x====x=====x=====
           ^                        ^                        ^
           A                        B                        C

x - a failure causing retry happens
= - operating normally
```

In the timeline above, intermittent failures start at point A, and each retry attempt contributes to the increase of the overall backoff schedule. Consequently, each subsequent retry allows more time for the system to recover. This schedule does not reset to its initial values until after the configured period of stability is reached following the last failure (point B), such as after operating without any failures for 5 minutes (point C).

30.5.2.5 Exit codes

PQS terminates with the following exit codes:

- 0: Normal termination
- 1: Termination due to unrecoverable error or all retry attempts for recoverable errors have been exhausted

30.5.3 Ledger Streaming & Recovery

On (re-)start, PQS determines last saved checkpoint and continues incremental processing from that point onward. PQS is able to start and finish at prescribed ledger offsets, specified via args:

```
$ ./scribe.jar pipeline --help-verbose

Usage: pipeline SOURCE TARGET [OPTIONS]
[...]
Options:
[...]
  --pipeline-ledger-start [enum | string]  Start offset (default: Latest)
                                           + Environment variable: SCRIBE_
↳ PIPELINE_LEDGER_START
                                           + System property:      pipeline.
↳ ledger.start
                                           + Enumeration values:  Genesis, □
↳ Oldest, Latest
  --pipeline-ledger-stop [enum | string]    Stop offset (default: Never)
                                           + Environment variable: SCRIBE_
↳ PIPELINE_LEDGER_STOP
                                           + System property:      pipeline.
↳ ledger.stop
                                           + Enumeration values:  Latest, □
↳ Never
[...]
```

Start offset meanings:

- Genesis: Commence from the first offset of the ledger, failing if not available.
- Oldest: Resume processing, or start from the oldest available offset of the ledger (if the data-store is empty).
- Latest: Resume processing, or start from the latest available offset of the ledger (if the data-store is empty).
- <offset>: Offset from which to start processing, terminating if it does not match the state of the datastore.

Stop offset meanings:

- Latest: Process until reaching the latest available offset of the ledger, then terminate.
- Never: Keep processing and never terminate.
- <offset>: Process until reaching this offset, then terminate.

In many scenarios `--pipeline-ledger-start=Oldest --pipeline-ledger-stop=Never` is the most appropriate configuration, for both initial population of all available history, and also catering for resumption/recovery processing.

Caution: If the ledger has been pruned beyond the offset specified in `--pipeline-ledger-start`, PQS fails to start. For more details see [History Slicing](#).

30.6 Read API

While data consumers do not communicate with the PQS process directly, they do use an API that PQS has provisioned in the database itself. This Read API is designed to provide a consistent and stable interface for users to access the ledger. It consists of a set of functions that should be the only database artifacts readers interact with.

30.6.1 How The Ledger Models Time

A key aspect to consider when querying the ledger is the fact that it makes the history over time available. Additionally, understanding time in a distributed environment can be challenging because there are many different clocks available. If you are familiar with Daml and its time model, skip this section and move to the section [Time Model](#).

30.6.1.1 Offset

A participant models time using an index called an *offset*. An offset is a unique index of the participant's local ledger. You can think of this as selecting an item in the ledger using a specific offset (or index) into the ledger.

Offsets are ordered, representing the order of transactions on the ledger of a participant. Due to privacy and filtering, the sequence of offsets of a participant usually appears to contain gaps.

Offsets are specific to a participant and are not consistent between peer participants - even when processing common transactions. This is because each participant has its own ledger and allocates its own offsets based on its permissioned view of transactions.

Offsets are represented as strings, encoded in zero-padded hexadecimal form. eg. `0000000000000000A8`

30.6.1.2 Ledger Time

Ledger time is an approximate wall-clock time (within a bounded skew) that preserves causal ordering. That is, if a contract is created at a certain time, it cannot be used until after that time. The ledger time is represented by the `created_at` field in the PQS Read API.

30.6.1.3 Transaction ID

A transaction ID corresponds to an offset in the following ways:

Not every offset has a transaction ID. For example, the completion event of a rejected transaction does not have a transaction ID because it was unsuccessful.

There is, at most, one transaction ID at a given offset.

Each transaction ID is unique and always has a single offset.

While offsets are allocated by, and are specific to, a participant; transaction ID values are common to all participants.

Transaction ordering (as represented by associated offset) can vary between participants.

A transaction ID is entirely opaque and does not communicate any information, other than identification.

30.6.1.4 Which should I use?

Different types of data analysis require different tools. For example in these types of analysis the following identifiers can be useful:

Causal: **Offset** provides an understanding of events in causal order, consistent with the Participant-determined ledger commit ordering.

Systematic: **Transaction ID** is required for correlating over multiple participants, serving as a common identifier for individual transactions.

Temporal: **Ledger Time** provides an ordering of events in wall-clock time, with bounded skew. This can be useful depending on your need for precision.

30.6.2 Time Model

PQS provides all three identifiers, but offset is defines the order. With this PQS is able to provide a consistent view of ledger transactions.

Offsets are deeply embedded in the Read API, allowing users to query the ledger in a manner that provides consistency. Users can nominate the offsets they wish to query, or simply query the latest available offset.

The following figure shows a pair of participants and their respective ledgers. Each participant has its own PQS instance, and you can see that it always has the portion of the ledger it is authorized to see:

You can also see that the offsets (prefix) are common to the participant and PQS, but the Transaction IDs (suffix) are shared throughout.

30.6.3 Offset Management

The following functions control the temporal perspective of the ledger, and allow you to control how you consider time in your queries. Since PQS exposes an eventually-consistent perspective of the ledger, you may wish to query:

Ignore; The *latest available* state.

Pin; The state of the ledger at a specific time.

Span; The ledger events across a time range, such as for an audit trail.

Consistency; The ledger in a way that maintains consistency with other interactions you have had with the ledger (read or write).

The following functions allow you to control the temporal scope of the ledger. This establishes the context in which subsequent queries execute:

`set_latest(offset)`: nominates the offset of the latest data to include in observing the ledger. If NULL it uses the latest available. The actual offset to be used is returned. If the supplied offset is beyond what is available, an error occurs.

`validate_offset_exists(offset)`: validates that the datastore has a complete history up to and including the offset provided. Returns an error if the nominated offset is not available (too old, or too new).

`set_oldest(offset)`: nominates the offset of the oldest events to include in query scope. If NULL then it uses the oldest available. Function returns the actual offset used. If the supplied offset is beyond what is available, an error occurs.

`nearest_offset(time)`: a helper function to determine the offset of a given time (or interval prior to now).

Under this scope, the following [table functions](#) allow access to the ledger and are used directly in queries. They are designed to be used in a similar manner to tables or views, and allow users to focus on the data they wish to query, with the impact of offsets removed.

`active(name)`: active instances of the target template/interface views that existed at the time of the latest offset

`creates(name)`: create events of the target template/interface views that occurred between the oldest and latest offset

`archives(name)`: archive events of the target template/interface views that occurred between the oldest and latest offset

`exercises(name)`: exercise events of the target choice that occurred between the oldest and latest offset

The above functions allow the user to focus on the templates, interfaces, and choices they wish to query without concern for [PostgreSQL name limits](#) that are more constraining than Daml identifiers. If you wish to allocate a SQL name, you can create a SQL VIEW in which you reference the above functions.

The name identifier can be used with or without the package specified:

Fully qualified: `<package>:<module>:<template|interface|choice>`

Partially qualified: `<module>:<template|interface|choice>`

Note: Partially qualified identifiers fail if there is an ambiguous result.

These functions have optional parameters to allow the user to specify the offset range to be used. Providing these arguments is alternative to using `set_*` functions prior in the session. The following queries are equivalent:

```
-- Implicit: geared towards context-oriented exploration
psql=# select set_oldest('0000000000000005000');
psql=# select set_latest('0000000000000006000');
psql=# select * from creates('package:My.Module:Template');
...

-- Explicit: beneficial to inline the entire context, to emit in a single
-- statement
psql=# select * from creates('package:My.Module:Template', '0000000000000005000',
-- '0000000000000006000');
...
```

30.6.4 JSONB Encoding

PQS stores the ledger using a [Daml-LF JSON-based encoding](#) of Daml-LF values. An overview of the encoding is provided below. For more details, refer to [the Daml-LF page](#).

Users should consult the [PostgreSQL documentation](#) to understand how to work with JSONB data natively in SQL.

Values on the ledger (contract payloads and keys, interface views, exercise arguments, and return values) can be primitive types, user-defined records, variants, or enums. These types translate to [JSON types](#) as follows:

30.6.4.1 Primitive Types

`ContractID`: represented as [string](#).
`Int64`: represented as [string](#).
`Decimal`: represented as [string](#).
`List`: represented as [array](#).
`Text`: represented as [string](#).
`Date`: days since the Unix epoch, represented as [integer](#).
`Time`: microseconds since the UNIX epoch, represented as [number](#).
`Bool`: represented as [boolean](#).
`Party`: represented as [string](#).
`Unit & Empty`: Represented as empty object `{}`.
`Optional`: represented as a variant with two constructors: `None` and `Some`.

30.6.4.2 User-Defined Types

`Record`: represented as [object](#), where each create parameter's name is a key, and the parameter's value is the JSON-encoded value.
`Variant`: represented as [object](#), using the `{constructor: body}` format, such as `{"Left": true}`.
`Enum`: represented as [string](#), where the value is the constructor name.

30.6.5 Querying Patterns

Scenario: A website user wants to query the state of the ledger after having completed a command (write), which has successfully committed at offset 0000000000000001350. The user does not want to see a version of the ledger prior to this, in order to appear consistent.

[!NOTE] This is a common pattern for web interfaces built on eventually-consistent data sources. It can be useful to track the latest offset within the web session, and update it on each interaction (read or write). Such offset is then used to protect any further reads from seeing prior versions.

```
-- fails if the offset is not yet available
SELECT validate_offset_exists("0000000000000001350");

-- this query only runs if the offset is available, and therefore the user can be
-- assured that the query does not return a prior version.
SELECT * FROM active('test:Test.User:User');
```

Scenario: A user wants to query the most recent available state of the ledger. This user treats the ledger's Active Contract Set as a database table and is not concerned with history or offsets. This user simply wants to query the (latest) state of the ledger, without consideration for offsets. Querying is inherently limited to one datasource, as the user has no control over the actual offset being used.

In this case the user wishes to query all Daml templates of `User` within the `Test.User` templates, where the user is not an administrator:

```
SELECT set_latest(NULL);

SELECT *
  FROM active('test:Test.User:User') AS "user"
 WHERE "user".payload->>'admin' = 'false';
```

By using PostgreSQL's JSONB querying capabilities, you can join with the related `Alias` template to provide an overview of all users and their aliases:

```
SELECT set_latest(NULL);

SELECT *
  FROM active('test:Test.User:User') AS "user"
 LEFT JOIN active('test:Test.User:Alias') AS "alias"
    ON "user".payload->>'user_id' = "alias".payload->>'user_id';
```

Historical events can also be accessed; by default all the history in the datastore is available for querying. The following query returns the data associated with all `User` contracts that were archived in the available history:

```
SELECT set_latest(NULL), set_oldest(NULL);

SELECT *
  FROM archives('test:Test.User:User') AS "archive"
 JOIN creates('test:Test.User:User') AS "user"
   USING contract_id;
```

Scenario: A report writer wants to query the ledger as of a known historical point in time, to ensure that consistent data is provided regardless of where the ledger subsequently evolved.

This user can obtain a point-in-time view of the ledger, to see all non-admin `User` templates that were active at that point in time:

```
SELECT set_latest(nearest_offset('2020-01-01 00:00:00+0'));

SELECT "user".*
  FROM active('test:Test.User:User') AS "user"
 WHERE "user".payload->>'admin' = 'false';
```

Scenario: Query the history of the ledger to determine how many aliases have existed for each user who was active at 2020-01-01:

```
SELECT set_latest(nearest_offset('2020-01-01 00:00:00+0')), set_oldest(NULL);

SELECT "user".user_id, COUNT(alias.*) AS alias_count
  FROM active('test:Test.User:User') AS "user"
```

(continues on next page)

(continued from previous page)

```
JOIN creates('test:Test.User:Alias') AS alias
  ON "user".payload->>'user_id' = alias.payload->>'user_id'
WHERE "user".payload->>'admin' = 'false';
```

Scenario: An automation user wants to query from a fixed offset (repeatable read consistency) and write their query in familiar SQL.

```
-- fails if the datastore has not yet reached the given offset
SELECT set_latest("0000000000000001250");

-- this query run at the nominated offset
SELECT ...
```

The above queries now observe active contracts as of the given offset. Therefore, the example queries presented above are unchanged.

Scenario: A user wants to present a limited amount of history to their users. They only want to see the last 90 days of history.

```
-- fails if this offset has already been pruned from the datastore
SELECT set_oldest(nearest_offset(INTERVAL '90 days'));

-- audit trail of all created users
SELECT * FROM creates('test:Test.User:User');
```

Scenario: A user wants to enquire where the datastore is up to, in terms of offset availability.

Here, the user requests the most recent and oldest available offsets to be used, and in the process returns what these offsets are:

```
SELECT set_latest(NULL) AS latest_offset,
       set_oldest(NULL) AS oldest_offset;
```

30.6.6 Summary functions

Summary functions are available to provide an overview of the ledger data available within the nominated offset range:

`summary_transients(from_offset, to_offset)`: the number of transients per Daml fully qualified name within the offset range.
`summary_updates(from_offset, to_offset)`: summary of create and archive counts per Daml fully qualified name within the offset range.

The following functions retrieve event counts per `template_fqn`:

```
summary_active(at_offset)
summary_creates(from_offset, to_offset)
summary_archives(from_offset, to_offset)
summary_exercises(from_offset, to_offset)
```

Valid values for `payload_type` are:

```
template
interface_view
```

```

consuming_choice
nonconsuming_choice

```

```

postgres=# select * from summary_active();
OR
postgres=# select * from summary_active('000000000000000000a');

template_fqn                                |payload_type|count|
-----+-----+-----+
QueryingPackage:NameRegistry:BirthCertificate|template    |    2|
QueryingPackage:NameRegistry:INameDocument   |interface   |    2|
(2 rows)

```

30.6.7 Lookup functions

`lookup_contract(contract_id)` is a mechanism to retrieve contract data without needing to know its Daml qualified name. The function returns both contract and all associated interface view projections, distinguishable by the `payload_type` column.

```

postgres=# select right(template_fqn, 64) template_fqn, fqn_type, "offset",
↳left(contract_id, 8) contract_id, left(event_id, 8) event_id, payload
from lookup_contract(
↳'0065497c49743b751946e7686fd853adc68b3081fc0e83bd418deb0d3fc4a5a610ca01122039fd9bf65a
↳');

        template_fqn          |      fqn_type       |      offset      |
↳contract_id | event_id |
↳
↳              payload
-----+-----+-----+-----+
↳-----+-----+-----+-----+
↳-----+-----+-----+-----+
↳-----+-----+-----+-----+
mypkg:PingPong:BirthCertificate | template          | 000000000000000009 |
↳0065497c      | #1220f9a | {"owner":
↳"Alice::122053a2c7fb4d821b2d09ee4da44f4f575b24312045a62eb65fbba050bf03ae4cc1
↳", "user_id": "id-joe", "lastName": "Bloggs", "firstName": "Fred"}
mypkg:PingPong:INameDocument   | interface_view    | 000000000000000009 |
↳0065497c      | #1220f9a | {"name": "Fred Bloggs", "owner":
↳"Alice::122053a2c7fb4d821b2d09ee4da44f4f575b24312045a62eb65fbba050bf03ae4cc1
↳"}

(2 rows)

```

`lookup_exercises(contract_id)` - a mechanism to retrieve choice exercise data without needing to know the Daml qualified name; knowing the contract ID is sufficient.

```

postgres=# select right(choice_fqn, 40) choice_fqn, right(template_fqn, 40)
↳template_fqn, fqn_type, exercised_at_offset, left(contract_id, 8) contract_
↳id, left(exercise_event_id, 8) exercise_event_id, argument, result
from lookup_exercises(
↳'009a92084a89683c6c2cdbec4231a068238e11a93ef6d8722c48d23acdce3d87fdca011220f554549ca0
↳');

        choice_fqn          |      template_fqn      |
↳fqn_type          | exercised_at_offset | contract_id | exercise_event_id |
↳
↳      argument      |
↳
↳      result

```

(continues on next page)

30.6.8 Optimization

This section briefly discusses optimizing the PQS database to make the most of the capabilities of PostgreSQL. The topic is broad, and there are many resources available. Refer to the [PostgreSQL documentation](#) for more information.

PQS makes extensive use of JSONB columns to store ledger data. Familiarity with JSONB is essential to optimize queries. The following sections provide some tips to help you get started.

30.6.8.1 Indexing

Indexes are an important tool for improving the performance of queries with JSONB content. Users are expected to create JSONB-based indexes to optimize their model-specific queries, where additional read efficiency justifies the inevitable write-amplification. Simple indexes can be created using the following helper function. More sophisticated indexes can be created using the standard PostgreSQL syntax.

```

call create_index_for_contract('token_wallet_holder_idx', 'register:DA.
↪Register:Token', '(payload->'wallet'->'holder')', 'hash');

```

In this example, the index allows comparisons on the wallet holder. It has the additional advantage that the results of the JSON inspection are cached/materialized and do not have to be recomputed for every access.

PostgreSQL provides several index types, including B-tree, Hash, GiST, SP-GiST, GIN, and BRIN. Each index type uses a different algorithm that is best suited to different types of queries. The table below provides a basic explanation of where they can be used. For a more thorough understanding, consult the [chapter on indexes](#) in the PostgreSQL manual.

Index Type	Comment
Hash	Compact. Useful only for filters that use =.
B-tree	Can be used in filters that use <, <=, =, >=, > as well as postfix string comparisons (e.g. LIKE 'foo%'). B-trees can also speed up ORDER BY clauses and can be used to retrieve subexpressions values from the index rather than evaluating the subexpressions (i.e. when used in a SELECT clause).
GIN	Useful for subset operators.
GiST, SP-GiST	See PostgreSQL manual.
BRIN	Efficient for tables where rows are already physically sorted for a particular column.

30.6.8.2 Pagination

Pagination refers to splitting up large result sets into pages of up to n results. It can allow user navigation, such as moving to the next page to display, going to the end of the result set, or jumping around in the middle. It can be a very effective user experience when there is a large ordered data set. The following pagination use cases are important:

Pagination Use Case		Example
Random access	Accessing arbitrary pages	Client-side binary search of results; A user opens random pages in a search result.
Iteration or enumeration	Accessing page 1, then page 2,	Programmatic processing of all results in batches iter.

For efficient pagination iteration, you need a stable column to sort on. The requirements are:

- It should be acceptable to the user to sort results on the column.

- It must have unique values.

- A unique B-tree index should exist.

You can then retrieve a page using queries with the specified `page_num` and of size `page_size`:

```
SELECT *
  FROM the_source
 ORDER BY the_key
  LIMIT page_size
  OFFSET (page_num * page_size);
```

Caution: Large `OFFSET` values become progressively slower, as increasing number of rows need to be read and discarded. See the chapter on [LIMIT and OFFSET](#) in the PostgreSQL manual.

Keyset pagination is a scalable and efficient method to use. This is a technique where you use the last value of the previous page to fetch the next page. The following query fetches the next page of results after the last value of the previous page. You should consider an appropriate index for the key column:

```
SELECT *
  FROM the_table
 WHERE the_key > prev_page_last_key
 ORDER BY the_key
 LIMIT page_size
```

30.6.8.3 psql Tips

Type `psql <dbname>` on the command line to enter the PostgreSQL REPL (if in doubt, use `postgres` as the database name). Some useful commands are shown in the following table:

Command	Description
<code>\l</code>	List all databases.
<code>\c database</code>	Switch to a different database.
<code>\d</code>	List all tables in the current database.
<code>\d table</code>	Show a table, including column types and indexes.

To manage users:

```
CREATE USER the_user WITH PASSWORD '*****';
GRANT SELECT, UPDATE, INSERT ON ALL TABLES IN SCHEMA postgres TO the_user;
ALTER DEFAULT PRIVILEGES IN SCHEMA postgres GRANT SELECT, UPDATE, INSERT ON
↳TABLES TO user;
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA postgres TO the_user;
GRANT CREATE ON postgres TO the_user;
DROP USER the_user;
```

`psql` can also be used for scripting:

```
$ psql postgres <<END
SELECT * FROM ...;
END
```

The script continues to execute if a command fails.

30.6.8.4 Query Analysis

In `psql` you can prefix a query with `EXPLAIN ANALYZE` to get an explanation of how the query would be executed. This helps verify that a query executes as expected, using the indexes that you expect it to.

```
EXPLAIN ANALYZE
SELECT COUNT(*) FROM ...;
```

30.7 Pruning

Pruning ledger data from the database can help reduce storage size and improve query performance by removing old and irrelevant data. PQS provides two approaches to prune ledger data: using the PQS CLI or using the `prune_to_offset` PostgreSQL function.

Warning: Calling either the `prune` CLI command with `--prune-mode Force` or calling the PostgreSQL function `prune_to_offset` deletes data irrevocably.

30.7.1 Data Deletion and Changes

Both pruning approaches (CLI and PostgreSQL function) share the same behavior in terms of data deletion and changes.

Active contracts are preserved under a new offset, while all other transaction-related data up to, and including the target offset is deleted. This approach is in line with ledger pruning [recommendation](#):

As a consequence, after pruning, a Daml application must bootstrap from the Active Contract Service and a recent offset.

PQS helps users avoid an unnecessary bootstrapping process, but achieves the same outcome as if it had obtained a fresh snapshot (of the Active Contract Set) from the ledger.

The target offset, that is, the offset provided via `--prune-target` or as argument to `prune_to_offset` is the transaction with the highest offset to be deleted by the pruning operation.

Note: If the provided offset does not have a transaction associated with it, the effective target offset becomes the oldest offset that succeeds (is greater than) the provided offset.

When using either pruning method, the following data will be changed:

The offset of active contracts is moved to the oldest known offset which succeeds the pruning target offset. For example, this could be the offset of the oldest transaction that is unaffected by the pruning operation.

Transactions with offsets up to and including the target offset, including associated archived contracts and exercise events, are deleted.

The following data is unaffected:

Transaction-related data (event/choices/contracts) for transaction with an offset greater than the pruning target.

Pruning is a destructive operation and cannot be undone. If necessary, make sure to back up your data before performing any pruning operations.

30.7.2 Constraints

Some constraints apply to pruning operations:

1. The provided target offset must be within the bounds of the contiguous history. If the target offset is outside the bounds, an error is raised.
2. The pruning operation cannot coincide with the latest consistent checkpoint of the contiguous history. If so, it raises an error.

30.7.3 Pruning from the command line

The PQS CLI provides a `prune` command that allows you to prune the ledger data up to a specified offset, timestamp, or duration.

For detailed information on all available options, please run `./scribe.jar datastore postgres-document prune --help-verbose`.

To use the `prune` command, you need to provide a pruning target as an argument. The pruning target can be an offset, a timestamp (ISO 8601), or a duration (ISO 8601):

```
$ ./scribe.jar datastore postgres-document prune --prune-target '<offset>'
...
```

By default, the `prune` command performs a dry run, meaning it displays the effects of the pruning operation without actually deleting any data. To execute the pruning operation, add the `--prune-mode Force` option:

```
$ ./scribe.jar datastore postgres-document prune --prune-target '<offset>' --
↪prune-mode Force
...
```

30.7.4 Example with Timestamp and Duration

In addition to providing an offset as `--prune-target`, a timestamp or duration can also be used as a pruning cut-off. For example, to prune data older than 30 days (relative to now), you can use the following command:

```
$ ./scribe.jar datastore postgres-document prune --prune-target P30D
...
```

To prune data up to a specific timestamp, you can use the following command:

```
$ ./scribe.jar datastore postgres-document prune --prune-target 2023-01-
↪30T00:00:00.000Z
...
```

30.7.5 Pruning from SQL

The `prune_to_offset()` function is a PostgreSQL function that allows you to prune the ledger data up to a specified offset. It has the same behavior as the `datastore postgres-document prune` command, but does not feature a dry-run option.

To use `prune_to_offset`, you need to provide an offset:

```
SELECT * FROM prune_to_offset('<offset>');
```

The function deletes transactions and updates active contracts as described above.

You can use `prune_to_offset` in combination with the `nearest_offset` function to prune data up to a specific timestamp or interval. For example, to prune data older than 30 days, you can use the following query:

```
SELECT * FROM prune_to_offset(nearest_offset(interval '30 days'));
```

30.8 Authentication

To run PQS with authentication you need to turn on via `--source-ledger-auth OAuth`. PQS uses [OAuth 2.0 Client Credentials flow](#) that requires additional `--pipeline-oauth` parameters:

```
--pipeline-oauth-clientid my_client_id \  
--pipeline-oauth-clientsecret deadbeef \  
--pipeline-oauth-cafile ca.crt \  
--pipeline-oauth-endpoint https://my-auth-server/token
```

PQS uses the supplied client credentials (`clientid` and `clientsecret`) to access the token endpoint (`endpoint`) of the OAuth service of your choice. Optional `cafile` parameter is a path to the Certification Authority certificate used to access the token endpoint. If `cafile` is not set, the Java TrustStore is used.

Please make sure you have [configured your Daml participant to use authorization](#) and an authorization server to accept your client credentials for `grant_type=client_credentials` and `scope=daml_ledger_api`.

Full example:

```
$ ./scribe.jar pipeline ledger postgres-document \  
  --source-ledger-auth OAuth \  
  --pipeline-oauth-clientid my_client_id \  
  --pipeline-oauth-clientsecret deadbeef \  
  --pipeline-oauth-cafile ca.crt \  
  --pipeline-oauth-endpoint https://my-auth-server/token  
  
03:32:02.407 I [zio-fiber-75] com.digitalasset.scribe.appversion.package:14  
  ↳ scribe, version: v0.0.1-main+3892  
03:32:02.671 I [zio-fiber-98] com.digitalasset.scribe.configuration.package:43  
  ↳ Applied configuration:  
[...]  
03:32:03.592 I [zio-fiber-90] com.digitalasset.auth.TokenService:76 Initialised  
  ↳ with tokenEndpoint=https://my-auth-server/token and clientId=my_client_id  
[...]
```

30.8.1 Audience-Based Token

For [Audience-Based Tokens](#) use the `--pipeline-oauth-parameters-audience` parameter:

```
$ ./scribe.jar pipeline ledger postgres-document \  
  --source-ledger-auth OAuth \  
  --pipeline-oauth-clientid my_client_id \  
  --pipeline-oauth-clientsecret deadbeef \  
  --pipeline-oauth-cafile ca.crt \  
  --pipeline-oauth-endpoint https://my-auth-server/token \  
  --pipeline-oauth-scope None \  
  --pipeline-oauth-parameters-audience https://daml.com/jwt/aud/participant/my_  
↪participant_id  
...
```

30.8.2 Scope-Based Token

For [Scope-Based Tokens](#) use the `--pipeline-oauth-scope` parameter:

```
$ ./scribe.jar pipeline ledger postgres-document \  
  --source-ledger-auth OAuth \  
  --pipeline-oauth-clientid my_client_id \  
  --pipeline-oauth-clientsecret deadbeef \  
  --pipeline-oauth-cafile ca.crt \  
  --pipeline-oauth-endpoint https://my-auth-server/token \  
  --pipeline-oauth-scope myScope \  
  --pipeline-oauth-parameters-audience https://daml.com/jwt/aud/participant/my_  
↪participant_id  
...
```

Note: The default value of the `--pipeline-oauth-scope` parameter is `daml_ledger_api`. Ledger API requires `daml_ledger_api` in the list of scopes unless [custom target scope](#) is configured.

30.8.3 Custom Daml Claims Tokens

Note: PQS authenticates as a user, as defined through the [User Identity Management](#) feature. Consequently, [Custom Daml Claims Access Tokens](#) are not supported. An audience-based or scope-based token must be used instead.

30.8.4 Static Access Token

Alternatively, you can configure PQS to use a static access token (meaning it is not refreshed) using the `--pipeline-oauth-accesstoken` parameter:

```
$ ./scribe.jar pipeline ledger postgres-document \
  --source-ledger-auth OAuth \
  --pipeline-oauth-accesstoken my_access_token
...
```

30.8.5 Ledger API Users and Daml Parties

PQS connects to a participant (via Ledger API) as a user, as defined through the [User Identity Management](#) feature. PQS gets its user identity by providing an OAuth token of that user. After authenticating, the participant has the authorization information to know what Daml Party data the user can access. By default, PQS subscribes to data for all parties available to PQS's authenticated user. However, this scope can be limited via the `--pipeline-filter-parties` filter parameter.

30.8.6 Token expiry

JWT tokens have an expiration time. PQS has a mechanism to automatically request a new access token from the Auth Server, before the old access token expires. To set when PQS should try to request a new access token, use `--pipeline-oauth-preemptexpiry` (default `PT1M` - one minute), meaning: request a new access token one minute before the current access token expires. This new access token is used for any future Ledger API calls. However, for streaming calls such as [getTransactions](#) the access token is part of the request that initiates the streaming. Canton versions prior to 2.9 terminate the stream with error `PERMISSION_DENIED` as soon as the old access token expires to prevent streaming forever based on the old access token. Versions 2.9+ fail with code `ABORTED` and description `ACCESS_TOKEN_EXPIRED` and PQS streams from the offset of the last successfully processed transaction.

30.9 History Slicing

As described in [Ledger Streaming & Recovery](#) you can use PQS with `--pipeline-ledger-start` and `--pipeline-ledger-stop` to ask for the slice of the history you want. There are some constraints on start and stop offsets which cause PQS to fail-fast if they are violated.

You cannot use:

1. **Offsets that are outside ledger history**

2. Pruned offsets or Genesis on pruned ledger

3. Offsets that lead to a gap in datastore history

4. Offsets that are before the PQS datastore history

Note: In the above examples:

Request represents offsets requested via `--pipeline-ledger-start` and `--pipeline-ledger-stop` arguments.

Participant represents the availability of unpruned ledger history in the participant.

Datastore represents data in the PQS database.

30.10 Reset Procedure

30.10.1 Reset

Reset-to-offset is a manual procedure that deletes all transactions from the PQS database after a given offset. This allows you to restart processing from the offset as if subsequent transactions have never been processed.

Warning: Reset is a dangerous, destructive, and permanent procedure that needs to be coordinated within the entire ecosystem and not performed in isolation.

Reset can be useful to perform a point-in-time rollback of the ledger in a range of circumstances. For example, in the event of:

1. **Unexpected new entities** - A new scope, such as a Party or template, appears in ledger transactions without coordination. That is, new transactions arrive without ensuring PQS is restarted - to ensure it knows about these new entities prior.
2. **Ledger roll-back** - If a ledger is rolled-back due to the disaster recovery process, you will need to perform a similar roll back with PQS. This is a manual process that requires coordination with the participant.

The procedure:

Stop any applications that use the PQS database.

Stop the PQS process.

Connect to the PostgreSQL as an administrator.

Prevent PQS database readers from interacting (`REVOKE CONNECT..`).

Terminate any other remaining connections:

```
SELECT pg_terminate_backend(pid) FROM pg_stat_activity WHERE pid <> pg_
↪backend_pid( ) AND datname = current_database( )..
```

Obtain a summary of the scope of the proposed reset and validate that the intended outcome matches your expectations by performing a dry run:

```
SELECT * FROM validate_reset_offset("00000000000000A8000")
```

Implement the destructive changes of removing all transactions after the given offset and adjust internal metadata to allow PQS to resume processing from the supplied offset:

```
SELECT * FROM reset_to_offset("00000000000000A8000")
```

Re-enable access for PQS database users: `GRANT CONNECT..`)

Wait for the Participant to be available post-repair.

Start PQS.

Conduct any remedial action required in PQS database consumers, to account for the fact that the ledger appears to be rolled back to the specified offset.

Start applications that use the PQS database and resume operation.

30.10.2 Constraints

The provided target offset must be within the bounds of the contiguous history. If the target offset is outside the bounds, it raises an error.

30.11 Logging

30.11.1 Log Level

Set log level with `--logger-level`. Possible values are `All`, `Fatal`, `Error`, `Warning`, `Info` (default), `Debug`, `Trace`:

```
--logger-level=Debug
```

30.11.2 Per-Logger Log Level

Use `--logger-mappings` to adjust the log level for individual loggers. For example, to remove Netty network traffic from a more detailed overall log:

```
--logger-mappings-io.netty=Warning \  
--logger-mappings-io.grpc.netty=Trace
```

30.11.3 Log Pattern

With `--logger-pattern`, use one of the predefined patterns, such as `Plain` (default), `Standard` (standard format used in DA applications), `Structured`, or set your own. Check [Log Format Configuration](#) for more details.

To use your custom format, provide its string representation, such as:
`--logger-pattern="%highlight{%fixed{1}{%level}} [%fiberId] %name:%line
%highlight{%message} %highlight{%cause} %kvs"`

30.11.4 Log Format for Console Output

Use `--logger-format` to set the log format. Possible values are `Plain` (default) or `Json`. These formats can be used for the `pipeline` command.

30.11.5 Log Format for File Output

Use `--logger-format` to set the log format. Possible values are `Plain` (default), `Json`, `PlainAsync` and `JsonAsync`. They can be used for the interactive commands, such as `prune`. For `PlainAsync` and `JsonAsync`, log entries are written to the destination file asynchronously.

30.11.6 Destination File for File Output

Use `--logger-destination` to set the path to the destination file (default: `output.log`) for interactive commands, such as `prune`.

30.11.7 Log Format and Log Pattern Combinations

Notice you need to use `%label{your_label}{format}` to describe a Json attribute-value pair.

30.12 Database Schema Evolution

This section describe how PQS manages the evolution of its database schema between releases. This is important for operators who need to understand what is involved in upgrading PQS to a new version, and how to troubleshoot any issues that may arise.

Note: The [Read API](#) (not the database schema) is the interface for downstream consumers of PQS. The schema is an implementation detail that will evolve in order to enhance functional and performance characteristics.

30.12.1 Baselining

Prior to version `v0.2.1` PQS did not have a schema versioning mechanism. At this version, PQS gained a schema management capability based on [Flyway](#). If upgrading from an older version, you will need to baseline your database schema as a one-off procedure. You can either:

Let PQS do it for you as part of the pipeline launch:

```
$ ./scribe.jar pipeline ledger postgres-document \
  --target-schema-autoapply true \
  --target-schema-baseline true \
  --target-postgres-database ...
```

Perform it as an isolated operation:

```
$ ./scribe.jar datastore postgres-document schema apply \
  --schema-baseline true \
  --postgres-database ...
```

The result is the addition of the version table along with the application of any subsequent patches:

```
postgres=# select * from flyway_schema_history;
-[ RECORD 1 ]-----
installed_rank | 1
version        | 001
description     | Baseline initial schema
type           | BASELINE
script         | Baseline initial schema
checksum       |
installed_by    | postgres
installed_on    | 2024-04-10 16:47:42.449063
execution_time  | 0
success        | t
-[ RECORD 2 ]-----
installed_rank | 2
version        | 002
description     | Make initializecontractimplements function idempotent
type           | SQL
script         | V002__Make_initializecontractimplements_function_idempotent.sql
checksum       | 1833119048
installed_by    | postgres
installed_on    | 2024-04-10 16:47:42.505723
execution_time  | 5
success        | t
```

30.12.2 Schema Upgrades

When running a new version, PQS automatically applies any missing patches to the schema. This means that new PQS releases seamlessly evolve the schema to the latest required version.

30.12.3 Schema Dump

Some deployment environments require far stricter access control than letting operational processes perform such intrusive database schema operations. PQS allows you to export the required schema to standard output, which can later be reviewed and applied by authorized operators.

The following command displays the latest required schema:

```
$ ./scribe.jar datastore postgres-document schema show \
--ledger-host ...
```

The output contains all SQL statements that are required to bring the schema up to the latest version and clearly demarcates each patch's contents:

```
/*****  
 * generated by scribe, version: UNSPECIFIED *  
 *****/  
  
-- >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>> --  
-- db/migration/V001__Create_initial_schema.sql (start) --  
-- >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>> --  
-- ... patch content ...  
-- <<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<<< --  
-- db/migration/V001 Create initial schema.sql (end) --
```

(continues on next page)

The Database Administrator can then review the output and apply the ones that are higher than the current latest entry in the `flyway_schema_history` table.

```
$ ./scribe.jar pipeline ledger postgres-document \
  --target-schema-autoapply false \
  ...
```

(continued from previous page)

```

09:25:52.153 I [zio-fiber-556] org.flywaydb.core.internal.schemahistory.

```

More detailed logs can be obtained by setting the log level to debug. Launch a PQS command with `--help` for more information, or refer to the [Logging](#) section.

30.12.5 Troubleshooting

30.12.5.1 Problem 1: An application's Flyway conflicts with PQS's Flyway

An application making use of the PQS datastore may also manage its own database migrations via Flyway - either embedded, command-line, or other supported means. An example of such a scenario is the creation of application specific indexes.

With default settings, the application's Flyway produces an error similar to the one seen below because its view of available/valid migrations is different from PQS's:

```

$ flyway -configFiles=conf/flyway.toml migrate
Flyway Community Edition 10.12.0 by Redgate

See release notes here: https://rd.gt/416ObMi
Database: jdbc:postgresql://localhost:5432/postgres (PostgreSQL 15.5)
ERROR: Validate failed: Migrations have failed validation
Migration checksum mismatch for migration version 001
-> Applied to database : -332813992
-> Resolved locally : 422692347
Either revert the changes to the migration, or run repair to update the schema
  ↳history.
Need more flexibility with validation rules? Learn more: https://rd.gt/3AbJUZE

```

Note: Here, the command-line Flyway was used for demonstration purposes. The same applies to other methods of running Flyway.

However, it is trivial to instruct the application's Flyway to use a different, non-default table name to store its versioning information, which allows both Flyways to coexist in the same database.

```
postgres=# select version, description, script, success from flyway_schema_
↳ history ;
 version |          description          | script | success |
-----+-----+-----+-----+
001      | Create initial schema         | V001__Create_initial_schema.sql | t
002      | Make initializecontractimplements function idempotent | V002__Make_initializecontractimplements_function_idempotent.sql | t
003      | Fix create index for contract | V003__Fix_create_index_for_contract.sql | t
004      | Add tmp to tx references cascade constraint | V004__Add_tmp_to_tx_references_cascade_constraint.sql | t
005      | Make watermark progression safer | V005__Make_watermark_progression_safer.sql | t
006      | Make checkpoint functions stable | V006__Make_checkpoint_functions_stable.sql | t
007      | Expose effective at           | V007__Expose_effective_at.sql | t
(7 rows)
```

```
$ flyway -configFiles=conf/flyway.toml migrate -table=myapp_version -
↳ baselineOnMigrate=true -baselineVersion=0
Flyway Community Edition 10.12.0 by Redgate

See release notes here: https://rd.gt/416ObMi
Database: jdbc:postgresql://localhost:5432/postgres (PostgreSQL 15.5)
Schema history table "public"."myapp_version" does not exist yet
Successfully validated 1 migration (execution time 00:00.029s)
Creating Schema History table "public"."myapp_version" with baseline ...
Successfully baselined schema with version: 0
Current version of schema "public": 0
Migrating schema "public" to version "1.0 - Add index on Ping sender"
Successfully applied 1 migration to schema "public", now at version v1.0
↳ (execution time 00:00.036s)
```

```
postgres=# select version, description, script, success from myapp_version ;
 version | description | script | success |
-----+-----+-----+-----+
0        | << Flyway Baseline >> | << Flyway Baseline >> | t
1.0      | Add index on Ping sender | V1.0__Add_index_on_Ping_sender.sql | t
(2 rows)
```

Now both PQS and the application can manage their own schema versions independently. Assuming the application limits itself to only adding indexes and other non-conflicting changes, the two Flyways can coexist without issues.

```
-- new PQS release applies missing migrations

Daml contracts are the fundamental unit of runtime data stored on the ledger. In addition to storing data, contracts allow attaching certain behaviors (expressed as template choices) to this data. Both a contract's data (its create event arguments) and a choice's exercise events (their input and output arguments) rely on strongly typed data structures.

These data structures can be likened to tables in a relational database, as described in the documentation introducing [Data Types](#). However, Daml enriches these structures to such an extent that direct Daml-to-relational mapping becomes impractical, leading you to consider Daml contracts and events as self-contained documents rather than relational rows. For this reason, PQS stores these contracts and events in PostgreSQL as [JSON documents](#), since a document form is a natural fit for Daml's more expressive data model.

To organize data access in a more relational-friendly manner, you need to build project-specific abstractions on top of what PQS provides in general terms. This document introduces techniques and patterns that can be used to help express Daml's world through relational means.

30.12.6 Mapping Daml Models to Relational World

The following code represents a data cluster related to issuer approval of a set of token changes for an issue. Irrelevant details are omitted.

```
type Quantity = Decimal

data Issue = Issue with issuer: Party; label: Text
data Wallet = Wallet with holder: Party; label: Text; locks: Set Lock
data Lock = Lock with notary: Party, label: Text

template IssuerApproval
  with
    requestor: Party
    transferId: Text
    issue: Issue
    opens: [ContractId TokenOpen]
    closes: [ContractId TokenClose]
  where
    signatory issue.issuer, requestor

template TokenOpen
  with
    delegate: Party
    token: Token
  where
    signatory delegate, walletSigs token.wallet
    observer token.issue.issuer

template TokenClose
  with
    delegate: Party
```

(continues on next page)

(continued from previous page)

```

token: Token
tokenCid: ContractId Token
where
  signatory delegate, walletSigs token.wallet
  observer token.issue.issuer

template Token
with
  issue: Issue          -- what
  wallet: Wallet        -- where
  quantity: Quantity    -- how many
  observers: Set Party
where
  signatory issue.issuer, walletSigs wallet
  ensure quantity /= 0.0
  observer observers

template Transfer
...
choice Transfer_Settle: [ContractId Token]
with
  issuerApprovals: [ContractId IssuerApproval]
controller requestor
do
  ...

```

In this example, you can see that the data model is rich and interconnected:

Rich value types are used, such as Quantity, Lock, Wallet and Issue, which are simply defined by reference.

An IssuerApproval contract references multiple TokenOpen and TokenClose contracts via their contract IDs.

A TokenClose contract references a single Token contract via its contract ID.

Navigable relationships with different cardinalities, but all unidirectional. For instance, TokenClose knows of Token and IssuerApproval knows of TokenOpen, but not vice-versa.

```

```

Postgres offers [robust tools](#) for working with JSON data, but they can be cumbersome for users who are not familiar with them. You could make this data more accessible in a more traditional (rectangular) relational manner. To achieve this:

- Map out templates' attributes to tables' columns.

- Establish Postgres's natural primary and foreign key relationships between tables.

- Compose queries that would allow you to further combine data from multiple sources.

30.12.7 Considerations

Daml's data model is more sophisticated than SQL, and cannot be mapped directly to a relational model.

Consider representing nested structures with multiple cardinalities, recursive structures, maps of values, and value objects without proper identities. While such task is problematic in general terms, it is feasible to do so for a specific models by introducing selectively flattened contents, and dropping irrelevant (or infrequently used) data elements from the view.

The payload of a contract is a JSON document that only references ledger terms (contract ID strings) in the body, not Postgres' efficient `bigint` key references. However, it is feasible to keep referencing contract IDs when navigating relationships, since all `__contracts_*` tables already have a matching index provided.

Finally, arguments and results of choices are defined using the same strongly typed data structures as the templates. This means that the same techniques could be applied to enrich the data of choice exercises for relational querying. However, most choice exercises are recommended to pass contract IDs instead of the full contract data, thus enabling direct linkage of input-output effects but requiring extra steps to expose the actual data pieces involved.

A major caveat to consider before choosing this as the go-to solution instead of focusing on state querying is that it may incur a significant performance penalty (as all queries involving containment scanning would experience). If the arguments/results are flat, then this may provide a neat way to enrich your choice exercises, exposing more essential data rather than technical details.

30.12.8 Definitions

Important: Although the examples below have a 1-to-1 match in terms of model-to-table mapping, this should not necessarily be the only approach. It is often better to pull multiple sources into a single view from the outset if it makes future data access easier. All the ideas mentioned above are still very relevant in this case.

```
create or replace view vw_issuer_approval as
select
  c.create_event_pk,
  c.contract_id,
  c.payload->'issue'->>'label' as security,
  c.payload->>'requestor' as requestor,
  c.payload->>'transferId' as transferId,
  array(select jsonb_array_elements_text(c.payload->'opens')) as opens,
  array(select jsonb_array_elements_text(c.payload->'closes')) as closes
from creates('IssuerApproval') c;

create or replace view vw_token_open as
select
  c.create_event_pk,
  c.contract_id,
  (c.payload->'token'->>'quantity')::numeric as quantity
from creates('TokenOpen') c;

create or replace view vw_token_close as
select
  c.create_event_pk,
  c.contract_id,
  (c.payload->'token'->>'quantity')::numeric as quantity,
  c.payload->>'tokenCid' as token
from creates('TokenClose') c;

create or replace view vw_token as
select
  c.create_event_pk,
  c.contract_id,
  c.payload->'wallet'->>'label' as wallet,
  (c.payload->>'quantity')::numeric as quantity
from creates('Token') c;

create or replace view vw_xfer_settle as
select e.exercise_event_pk,
       e.exercise_event_id,
       array(select jsonb_array_elements_text(e.argument->'issuerApprovals')) as
       ↪approvals,
       array(select jsonb_array_elements_text(e.result)) as tokens
from exercises('TransferSettle') e;

-- add some indexes that may speed up queries
call create_index_for_contract('issuerapproval_xferid', 'DA.
       ↪Register:IssuerApproval', '(payload->>'transferId')', 'btree', 'text_pattern_
       ↪ops');
call create_index_for_contract('tokenopen_qty', 'DA.Register:TokenOpen',
       ↪'((payload->'token'->>'quantity')::numeric)', 'btree');
```

(continues on next page)

(continued from previous page)

```
call create_index_for_contract('token_qty', 'DA.Register:Token', '((payload->>'
  ↳ 'quantity')::numeric)', 'btree');
```

30.12.9 Queries & Results

The two contrived examples provided here demonstrate how PQS's data can be turned almost indistinguishable to what one would expect to see in a typical relational database without too much maintenance overhead. Timings are provided as the result of execution over a non-trivial database size - more details can be found [here](#).

30.12.10 Performance Optimizations

Assuming you could arrive to a set of composable SQL abstractions that allow you to express ledger data in relational terms, the next step is to ensure that the performance of your queries is acceptable for your needs. When examining the query plan for one of the queries mentioned above, you can observe that PostgreSQL's cost estimates are extremely high. The core problem is that JSON documents do not have granular statistics which would allow it to choose the best way of running the query. A secondary problem is that the exercises query runs predicates over data inside arrays, which complicates the plan even further.

Scenarios such as this can be overcome by materializing the results of your abstractions through either:

- Materialized views; or
- Custom triggers

30.12.10.1 Materialized Views

One way to speed up your queries, depending on your use case, is to opt for materialized views. Note that materialized views are not automatically updated when the underlying data changes (see some ideas how to deal with it [here](#)). The following code demonstrates how materialized views could benefit the queries under consideration:

```
create or replace function cid_to_pk(cid text) returns bigint as $$
select create_event_pk from __contracts where contract_id = cid;
$$ language sql;

create materialized view mvw_token_open as
select
    c.create_event_pk,
    c.contract_id,
    (c.payload->'token'->'quantity')::numeric as quantity
from creates('TokenOpen') c;
create index mvw_token_open_pk_idx on mvw_token_open (create_event_pk);

create materialized view mvw_token_close as
select
    c.create_event_pk,
    c.contract_id,
    (c.payload->'token'->'quantity')::numeric as quantity,
    cid_to_pk(c.payload->'tokenCid') as token
from creates('TokenClose') c;
create index mvw_token_close_pk_idx on mvw_token_close (create_event_pk);

create materialized view mvw_token as
select
    c.create_event_pk,
    c.contract_id,
    c.payload->'wallet'->'label' as wallet,
    (c.payload->'quantity')::numeric as quantity
from creates('Token') c;
create index mvw_token_pk_idx on mvw_token (create_event_pk);

create materialized view mvw_issuer_approval_to_token_open as
select
    c.create_event_pk as issuer_approval_pk,
    op.pk as token_open_pk
from creates('IssuerApproval') c
join lateral ( select cid_to_pk(cid) as pk from jsonb_array_elements_text(c.
    ↪payload->'opens') as cid ) op on true;
create index mvw_issuer_approval_to_token_open_iapk_idx on mvw_issuer_approval_to_
    ↪token_open (issuer_approval_pk);
create index mvw_issuer_approval_to_token_open_topk_idx on mvw_issuer_approval_to_
    ↪token_open (token_open_pk);

create materialized view mvw_issuer_approval_to_token_close as
select
    c.create_event_pk as issuer_approval_pk,
    cl.pk as token_close_pk
from creates('IssuerApproval') c
join lateral ( select distinct cid_to_pk(cid) as pk from jsonb_array_elements_
    ↪text(c.payload->'closes') as cid ) cl on true;
```

```

Observe that both query timings are extremely fast. This is because the data is now essentially in flattened tables with indexes, which allows Postgres to use its full capabilities, as reflected in the query plans.

30.12.10.2 Custom Triggers

Another option is to take a less declarative approach and use custom triggers to maintain the desired tables. While this approach offers greater flexibility and enables the implementation of more complex logic, it also demands more effort to maintain.

```

-- necessary tables
create table tbl_tokens (create_event_pk bigint, contract_id text, wallet text,
↪quantity numeric);
create index tbl_tokens_pk_idx on tbl_tokens (create_event_pk);

create table tbl_token_opens (create_event_pk bigint, contract_id text, quantity
↪numeric);
create index tbl_token_opens_pk_idx on tbl_token_opens (create_event_pk);

create table tbl_token_closes (create_event_pk bigint, contract_id text, quantity
↪numeric, token_pk bigint);
create index tbl_token_closes_pk_idx on tbl_token_closes (create_event_pk);

create table tbl_issuer_approvals(create_event_pk bigint, contract_id text,
↪security text, requestor text, transferId text);
create index tbl_issuer_approval_pk_idx on tbl_issuer_approvals (create_event_pk);

create table tbl_issuer_approval_to_token_open (issuer_approval_pk bigint, token_
↪open_pk bigint);
create index tbl_issuer_approval_to_token_open_iapk_idx on tbl_issuer_approval_to_
↪token_open (issuer_approval_pk);
create index tbl_issuer_approval_to_token_open_topk_idx on tbl_issuer_approval_to_
↪token_open (token_open_pk);

```

(continues on next page)

(continued from previous page)

```

Time: 1.915 ms

```

Query timings are in line with those of the materialized views. Note that triggers are executed as part of the transaction during underlying inserts, so care should be taken not to introduce performance bottlenecks with additional processing. In the example, the triggers are simple enough to avoid significant overhead:

```
-- ingestion benchmark
[watermark_ix]
First reading: 179 @ 1710197030847
Last reading: 40565095 @ 1710198940757
PQS throughput: 21,239 tx/s (101,289 ledger events/sec)

-- ingestion with triggers
[watermark_ix]
First reading: 214 @ 1713833930948
Last reading: 40565095 @ 1713835912812
PQS throughput: 20,468 tx/s (97,610 ledger events/sec)
```

Compared to the materialized views approach, custom triggers incur the maintenance cost upfront during ingestion, while views defer this cost over time, albeit at the expense of data availability/re-cency.

30.12.11 Trade-Offs Summary

The table below summarizes the trade-offs against various dimensions across the approaches discussed in this document.

Characteristic	Views	Materialized Views	Triggers
Definition	declarative	declarative	procedural
Data Availability	immediate	lagging (on refresh schedule)	immediate
Indexable	over JSONB column	over actual columns	over actual columns
Statistics	crude	detailed	detailed
Write Path Impact	none	none	slows down ingestion transaction

Caution: PQS's Read API functions not only expose ledger's events as first-class citizens through the use of `creates()`, `archives()`, `active()`, and `exercises()`, but also enable advanced querying capabilities, such as running a query as of a fixed point in time (as of a particular offset). This powerful feature is not provided by the relational approach described above. However, it is possible to combine the two approaches by supplying additional joins to enrich the resulting outcomes.

```
select ...
  from tbl_issuer_approvals ia
  ...
  inner join active('DA.Register:IssuerApproval', 'some_offset') ac on ac.create_
  event_pk = ia.create_event_pk
  ...
```

30.13 Observability

This page describes observability features of PQS, which are designed to help you monitor health and performance of the application.

30.13.1 Underlying Mechanism

PQS opted to incorporate OpenTelemetry APIs to provide its observability features. All three sources of signals (traces, metrics, and logs) can be exported to various backends by providing appropriate configuration defined by OpenTelemetry protocols and guidelines. This makes PQS flexible in terms of observability backends, allowing users to choose what fits their needs and established infrastructure without being overly prescriptive.

To have PQS emit observability data, an OpenTelemetry Java Agent must be attached to the JVM running PQS. OpenTelemetry's documentation page on [Automatic Instrumentation](#) has all the necessary information to get started.

As a frequently requested shortcut (only metrics over Prometheus exposition endpoint embedded by PQS), the following snippet can help you get started. For more details, refer to the official documentation:

```
export OTEL_SERVICE_NAME=scribe
export OTEL_TRACES_EXPORTER=none
export OTEL_LOGS_EXPORTER=none
export OTEL_METRICS_EXPORTER=prometheus
export OTEL_EXPORTER_PROMETHEUS_PORT=9090
export JDK_JAVA_OPTIONS="-javaagent:path/to/opentelemetry-javaagent.jar"
./scribe.jar pipeline ledger postgres-document ...
```

```
services:
  scribe:
    image: scribe:X.Y.Z
    # ...
    environment:
      JDK_JAVA_OPTIONS: "-javaagent:path/to/opentelemetry-javaagent.jar"
      OTEL_SERVICE_NAME: scribe
      OTEL_TRACES_EXPORTER: none
      OTEL_LOGS_EXPORTER: none
      OTEL_METRICS_EXPORTER: prometheus
      OTEL_EXPORTER_PROMETHEUS_PORT: 9090
    # ...
```

30.13.2 Provided Metrics

Assuming PQS exposes metrics as described above, you can access the following metrics at `http://localhost:9090/metrics`. Each metric is accompanied by `# HELP` and `# TYPE` comments, which describe the meaning of the metric and its type, respectively.

Some metric types have additional constituent parts exposed as separate metrics. For example, a histogram metric type tracks `max`, `count`, `sum`, and `actual ranged buckets` as separate time series. Metrics are labeled where it makes sense, providing additional context such as the type of operation or the template/choice involved.

Conceptual list of metrics (refer to actual metric names in the Prometheus output):

Type	Name	Description
gauge	watermark_ix	Current watermark index (transaction)
counter	pipeline_events	Processed ledger events
histogram	jdbc_conn_use	Latency of database connections usage
histogram	jdbc_conn_isvalid	Latency of database connection validation
histogram	jdbc_conn_commit	Latency of database connection commit
gauge	tx_lag_from_ledger_wallclock	Lag from ledger (wall-clock delta (in ms))
histogram	pipeline_convert_acs_event	Latency of converting ACS events
histogram	pipeline_convert_transaction	Latency of converting transactions
histogram	pipeline_prepare_batch_latency	Latency of preparing batches of statements
histogram	pipeline_execute_batch_latency	Latency of executing batches of statements
histogram	pipeline_progress_watermark_latency	Latency of watermark progression
histogram	pipeline_wp_acs_events_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_acs_statements_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_acs_batched_statements_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_acs_prepared_statements_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_events_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_statements_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_batched_statements_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_prepared_statements_size	Number of in-flight units of work in pipeline
histogram	pipeline_wp_watermarks_size	Number of in-flight units of work in pipeline
counter	pipeline_wp_acs_events_total	Number of units of work processed in pipeline
counter	pipeline_wp_acs_statements_total	Number of units of work processed in pipeline
counter	pipeline_wp_acs_batched_statements_total	Number of units of work processed in pipeline
counter	pipeline_wp_acs_prepared_statements_total	Number of units of work processed in pipeline
counter	pipeline_wp_events_total	Number of units of work processed in pipeline
counter	pipeline_wp_statements_total	Number of units of work processed in pipeline
counter	pipeline_wp_batched_statements_total	Number of units of work processed in pipeline
counter	pipeline_wp_prepared_statements_total	Number of units of work processed in pipeline
counter	pipeline_wp_watermarks_total	Number of units of work processed in pipeline
counter	app_restarts	Tracks number of times recoverable failure
gauge	grpc_up	Indicator whether gRPC channel is up and
gauge	jdbc_conn_pool_up	Indicator whether JDBC connection pool

30.13.3 Example Dashboard

Based on the metrics described above, it is possible to build a comprehensive dashboard to monitor PQS. Included in the PQS artifact, are a set of example dashboards for Grafana versions 9, 10 and 11. You may want to refer to these as a starting point for your own:

```

scribe.jar
grafana/v9.4.0/dashboard.json
grafana/v10.4.0/dashboard.json
grafana/v11.0.0/dashboard.json

```

30.13.4 Health Check

The health of the PQS process can be monitored using the health check endpoint `/livez`. The health check endpoint is available on the configured network interface (`--health-host`) and TCP port (`--health-port`). Note the default is `127.0.0.1:8080`.

```
$ curl http://localhost:8080/livez
{"status":"ok"}
```

30.13.5 Tracing of Pipeline Execution

PQS instruments the most critical parts of its operations with tracing to provide insights into the execution flow and performance. Traces can be exported to various OpenTelemetry backends by providing appropriate configuration, for example:

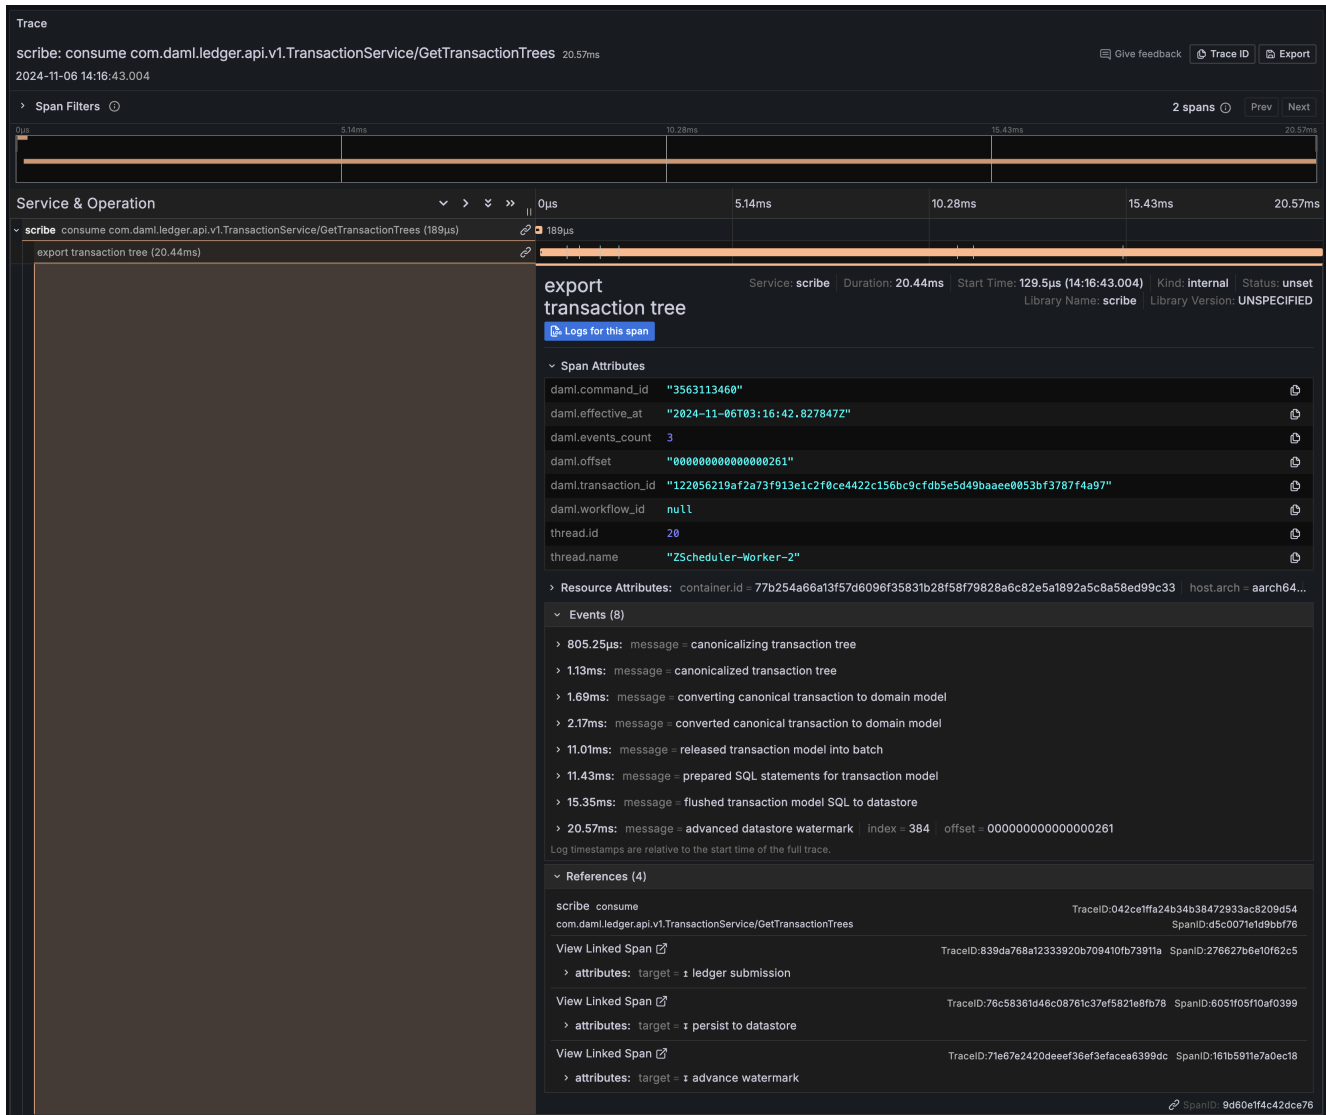

```
export OTEL_TRACES_EXPORTER=otlp
export OTEL_EXPORTER_OTLP_PROTOCOL=grpc
export OTEL_EXPORTER_OTLP_ENDPOINT="http://otel-collector:4317"
export JDK_JAVA_OPTIONS="-javaagent:path/to/opentelemetry-javaagent.jar"
./scribe.jar pipeline ledger postgres-document ...
```

The following root spans are emitted by PQS:

span name	description
process metadata and schema	interactions that happen when PQS starts up and ensures its datastore is ready for operations
initialization routine	interactions that happen when PQS establishes its offset range boundaries (including seeding from ACS if requested) on startup
consume com.daml.ledger.api.v1.TransactionService/GetTransactionsconsume com.daml.ledger.api.v1.TransactionService/GetTransactionTrees	[Daml SDK v2.x] timeline of processing a ledger transaction from delivery over gRPC to its persistence to datastore
consume com.daml.ledger.api.v2.UpdateService/GetUpdatesconsume com.daml.ledger.api.v2.UpdateService/GetUpdateTrees	[Daml SDK v3.x] timeline of processing a ledger transaction from delivery over gRPC to its persistence to datastore
execute datastore transaction	interactions when a batch of transactions is persisted to the datastore
advance datastore watermark	interactions when the latest consecutive watermark is persisted to the datastore

All spans are enriched with contextual information through OpenTelemetry's attributes and events where appropriate. It is advisable to get to know this contextual data. Due to the technical nature of asynchronous and parallel execution, PQS heavily employs [span links](#) to highlight causal relationships between independent traces. Modern trace visualisation tools leverage this information to provide a usable representation and navigation through the involved traces.

Below is an example of causal trace data that spans from the receipt of a transaction from the Ledger API to it becoming visible by PQS's [Read API](#) in Postgres.

```

30.13.6 Trace Context Propagation

PQS is an intermediary between a ledger instance and downstream applications that access data through SQL rather than by streaming directly from the Ledger API. Despite forming a pipeline between two data storage systems (Canton and Postgres), PQS stores the [original ledger transaction's trace context](#) for propagation. This allows downstream applications to decide for themselves how they want to connect to the original submission's trace (as a child span or as a new trace connected through [span links](#)).

```

scribe=# select "offset", (trace_context).trace_parent, (trace_context).trace_
↪state from __transactions limit 1;
      offset              |              trace_parent              | 
↪trace_state

Accessing data stored in PQS's `__transactions.trace_context` column allows any application to re-create the propagated [trace context](#) and use it with their runtime's instrumentation library.

30.14 Redaction

The redaction feature enables removal of sensitive or personally identifiable information from contracts and exercises within the PQS database. This operation is particularly useful for complying with privacy regulations and data protection laws, as it enables the permanent removal of contract payloads, contract keys, choice arguments, and choice results. Note that redaction is a destructive operation and once redacted, information cannot be restored.

The redaction process involves assigning a `redaction_id` to a contract or an exercise and nullifying its sensitive data fields. For contracts, the `payload` and `contract_key` fields are redacted, while for exercises, the `argument` and `result` fields are redacted.

30.14.1 Conditions for Redaction

The following conditions apply to contracts and interface views:

- You cannot redact an active contract.
- A redacted contract cannot be redacted again.

There are no restrictions on the redaction of choice exercise events.

A redaction operation requires a redaction ID, which is an arbitrary label to identify the redaction and provide information about its reason, and correlate with other systems that coordinate such activity.

30.14.2 Examples

30.14.2.1 Redacting an Archived Contract

To redact an archived contract, use the `redact_contract` function by providing the `contract_id` and a `redaction_id`. The intent of the `redaction_id` is to provide a case reference to identify the reason why the redaction has taken place, and it should be set according to organizational policies. This operation NULLs the `payload` and `contract_key` of the contract and assigns the `redaction_id`.

```
SELECT redact_contract('<contract_id>', '<redaction_id>');
```

Redaction is applied to the contract and its interface views, if any, and it returns the number of affected entries.

30.14.2.2 Redacting a Choice Exercise

To redact an exercise, use the `redact_exercise` function by providing the `event_id` of the exercise and a `redaction_id`. This NULLs the `argument` and `result` of the exercise and assigns the `redaction_id`.

```
SELECT redact_exercise('<event_id>', '<redaction_id>');
```

30.14.3 Accessing Redaction Information

The `redaction_id` of a contract is exposed as a column in the following functions of the read API. The columns `payload` and `contract_key` for a redacted contract are NULL.

```
creates(...)
archives(...)
active(...)
lookup_contract(...)
```

The `redaction_id` of an exercise event is exposed as a column in the following functions of the read API. The columns `argument` and `result` for a redacted exercise are NULL:

```
exercises(...)
lookup_exercises(...)
```

Chapter 31

Identity Management

On-ledger identity management focuses on the distributed aspect of identities across Canton system entities, while user identity management focuses on individual participants managing access of their users to their ledger APIs.

Canton comes with a built-in identity management system used to manage on-ledger identities. The technical details are explained in the [architecture section](#), while this write-up here is meant to give a high level explanation.

The identity management system is self-contained and built without a trusted central entity or pre-defined root certificate such that anyone can connect with anyone, without the need for some central approval and without the danger of losing self-sovereignty.

31.1 Introduction

31.1.1 What is a Canton Identity?

When two system entities such as a participant, sync domain topology manager, mediator or sequencer communicate with each other, they will use asymmetric cryptography to encrypt messages and sign message contents such that only the recipient can decrypt the content, verify the authenticity of the message, or prove its origin. Therefore, we need a method to uniquely identify the system entities and a way to associate encryption and signing keys with them.

On top of that, Canton uses the contract language Daml, which represents contract ownership and rights through [parties](#). But parties are not primary members of the Canton synchronization protocol. They are represented by participants and therefore we need to uniquely identify parties and relate them to participants, such that a participant can represent several parties (and in Canton, a party can be represented by several participants).

31.1.2 Unique Identifier

A Canton identity is built out of two components: a random string X and a fingerprint of a public key N . This combination, (X, N) , is called a *unique identifier* and is assumed to be globally unique by design. This unique identifier is used in Canton to refer to particular parties, participants, or sync domain entities. A system entity (such as a party) is described by the combination of role (party, participant, mediator, sequencer, sync domain topology manager) and its unique identifier.

The system entities require knowledge about the keys that are used for encryption and signing by the respective other entities. This knowledge is distributed and therefore, the system entities require a way to verify that a certain association of an entity with a key is correct and valid. This is the purpose of the fingerprint of a public key in the unique identifier, which is referred to as *Namespace*. The secret key of the corresponding namespace acts as the *root of trust* for that particular namespace, as explained later.

31.1.3 Topology Transactions

In order to remain flexible and be able to change keys and cryptographic algorithms, we don't identify the entities using a single static key, but we need a way to dynamically associate participants or sync domain entities with keys and parties with participants. We do this through topology transactions.

A topology transaction establishes a certain association of a unique identifier with either a key or a relationship with another identifier. There are several different types of topology transactions. The most general one is the `OwnerToKeyMapping`, which as the name says, [associates a key with a unique identifier](#). Such a topology transaction will inform all other system entities that a certain system entity is using a specific key for a specific purpose, such as participant *Alice* of namespace *12345..* is using the key identified through the fingerprint *AABBCCDDEE..* to sign messages.

Now, this poses two questions: who authorizes these transactions, and who distributes them?

For the authorization, we need to look at the second part of the unique identifier, the *Namespace*. A topology transaction that refers to a particular unique identifier operates on that namespace and we require that such a topology transaction is authorized by the corresponding secret key through a cryptographic signature of the serialized topology transaction. This authorization can be either direct, if it is signed by the secret key of the namespace, or indirect, if it is signed by a delegated key. To delegate the signing right to another key, there are other topology transactions of type `NamespaceDelegation` or `IdentifierDelegation` that allow one to do that. A [namespace delegation](#) delegates entire namespaces to a certain key, such as saying the key identifier through the fingerprint *AABBCCDDEE* is now allowed to authorize topology transactions within the namespace of the key *VVWWXXYYZZ*. An [identifier delegation](#) delegates authority over a certain identifier to a key, which means that the delegation key can only authorize topology transactions that act on a specific identifier and not the entire namespace.

Signing of topology transactions happens in a `TopologyManager`. Canton has many topology managers. Every participant node and every sync domain have topology managers with exactly the same functional capabilities, just different impacts. They can create new keys, new namespaces, and the identity of new participants, parties, and sync domains. And they can export these topology transactions such that they can be imported by another topology manager. This allows you to manage Canton identities in quite a wide range of ways. A participant can operate their own topology manager which allows them individually to manage their parties. Or they can associate themselves with another topology manager and let them manage the parties that they represent or keys they use. Or something in between, depending on the introduced delegations and associations.

The difference between the sync domain topology manager and the participant topology manager is that the sync domain topology manager establishes the valid topology state in a particular sync domain by distributing topology transactions in a way that every sync domain member ends up with the same topology state. However, the sync domain topology manager is just a gatekeeper of the sync domain that decides who is let in and who is not on that particular sync domain, but the actual topology statements originate from various sources. As such, the sync domain topology manager can only block the distribution, but cannot fake topology transactions.

The participant topology manager only manages an isolated topology state. However, there is a dispatcher attached to this particular topology manager that attempts to register locally registered identities with remote sync domains, by sending them to the sync domain topology managers, who then decide on whether they want to include them or not.

The careful reader will have noted that the described identity system indeed does not have a single root of trust or decision maker on who is part of the overall system or not. But also that the topology state for the distributed synchronization varies from sync domain to sync domain, allowing very flexible topologies and setups.

31.1.4 Legal Identities

In Canton, we separate a system identity from the legal identity. While the above mechanism allows to establish a common, verified and authorized knowledge of system entities, it doesn't guarantee that a certain unique identifier really corresponds to a particular legal identity. Even more so, while the unique identifier remains stable, a legal identity might change, for example in the case of a merger of two companies. Therefore, Canton provides an administrative command which allows one to associate a randomized system identity with a human readable *display name* using the `participant.parties.set_display_name` command.

Note: A party display name is private to the participant. If such names should be shared among participants, we recommend to build a corresponding Daml workflow and some automation logic, listening to the results of the Daml workflow and updating the display name accordingly.

31.1.5 Life of a Party

In the tutorials, we use the `participant.parties.enable("name")` function to setup a party on a participant. To understand the identity management system in Canton, it helps to look at the steps under the hood of how a new party is added:

1. The `participant.parties.enable` function determines the unique identifier of the participant: `participant.id`.
2. The party name is built as `name: :<namespace>`, where the `namespace` is the one of the participant.
3. A new party-to-participant mapping is authorized on the Admin API: `participant.topology.party_to_participant_mappings.authorize(...)`
4. The `ParticipantTopologyManager` gets invoked by the GRPC request, creating a new `SignedTopologyTransaction` and tests whether the authorization can be added to the local topology state. If it can, the new topology transaction is added to the store.
5. The `ParticipantTopologyDispatcher` picks up the new transaction and requests the addition on all sync domains via the `RegisterTopologyTransactionRequest` message sent to the topology manager through the sequencer.

6. A sync domain receives this request and processes it according to the policy (open or permissioned). The default setting is open.
7. If approved, the request service attempts to add the new topology transaction to the `DomainTopologyManager`.
8. The `DomainTopologyManager` checks whether the new topology transaction can be added to the sync domain topology state. If yes, it gets written to the local topology store.
9. The `DomainTopologyDispatcher` picks up the new transaction and sends it to all participants (and back to itself) through the sequencer.
10. The sequencer timestamps the transaction and embeds it into the transaction stream.
11. The participants receive the transaction, verify the integrity and correctness against the topology state and add it to the state with the timestamp of the sequencer, such that everyone has a synchronous topology state.

Note that the `participant.parties.enable` macro only works if the participant controls their namespace themselves, either directly by having the namespace key or through delegation (via `NamespaceDelegation`).

31.1.6 Participant Onboarding

Key to supporting topological flexibility is that participants can easily be added to new synchronizers. Therefore, the on-boarding of new participants to sync domains needs to be secure but convenient. Looking at the console command, we note that in most examples, we are using the `connect` command to connect a participant to a sync domain. The `connect` command just wraps a set of admin-api commands:

```
val certificates = OptionUtil.emptyStringAsNone(certificatesPath).map { path =>
  BinaryFileUtil.readByteStringFromFile(path) match {
    case Left(err) => throw new IllegalArgumentException(s"failed to load $path:
    ↪$err")
    case Right(bs) => bs
  }
}
DomainConnectionConfig.grpc(
  SequencerAlias.Default,
  domainAlias,
  connection,
  manualConnect,
  domainId,
  certificates,
  priority,
  initialRetryDelay,
  maxRetryDelay,
  timeTrackerConfig,
)
```

```
// register the domain configuration
register(config.copy(manualConnect = true))
if (!config.manualConnect) {
  // fetch and confirm domain agreement
  if (config.sequencerConnections.nonBftSetup) { // agreement is removed with the
  ↪introduction of BFT domain.
    confirm_agreement(config.domain.unwrap)
  }
}
```

(continues on next page)

(continued from previous page)

```

reconnect(config.domain.unwrap, retry = false).discard
// now update the domain settings to auto-connect
modify(config.domain.unwrap, _.copy(manualConnect = false))
}

```

We note that from a user perspective, all that needs to happen by default is to provide the connection information and accept the terms of service (if required by the sync domain) to set up a new sync domain connection. There is no separate onboarding step performed, no giant certificate signing exercise happens, everything is set up during the first connection attempt. However, quite a few steps happen behind the scenes. Therefore, we briefly summarise the process here step by step:

1. The administrator of an existing participant needs to invoke the `domains.register` command to add a new sync domain. The mandatory arguments are a sync domain *alias* (used internally to refer to a particular connection) and the sequencer connection URL (http or https) including an optional port `http[s]://hostname[:port]/path`. Optional are a certificates path for a custom TLS certificate chain (otherwise the default jre root certificates are used) and the sync domain ID of a sync domain. The *sync domain ID* is the unique identifier of the sync domain that can be defined to prevent man-in-the-middle attacks (very similar to an SSH key fingerprint).
2. The participant opens a GRPC channel to the `SequencerConnectService`.
3. The participant contacts the `SequencerConnectService` and checks if using the sync domain requires signing specific terms of services. If required, the terms of service are displayed to the user and an approval is locally stored at the participant for later. If approved, the participant attempts to connect to the sequencer.
4. The participant verifies that the remote sync domain is running a protocol version compatible with the participant's version using the `SequencerConnectService.handshake`. If the participant runs an incompatible protocol version, the connection will fail.
5. The participant downloads and verifies the sync domain ID from the sync domain. The *sync domain ID* can be used to verify the correct authorization of the topology transactions of the sync domain entities. If the sync domain ID has been provided previously during the `domains.register` call (or in a previous session), the two IDs are compared. If they are not equal, the connection fails. If the sync domain ID was not provided during the `domains.register` call, the participant uses and stores the one downloaded. We assume here that the sync domain ID is obtained by the participant through a secure channel such that it is sure to be talking to the right sync domain. Therefore, this secure channel can be either something happening outside of Canton or can be provided by TLS during the first time we contact a sync domain.
6. The participant downloads the *static sync domain parameters*, which are the parameters used for the transaction protocol on the particular sync domain, such as the cryptographic keys supported by this sync domain.
7. The participant connects to the sequencer initially as an unauthenticated member. Such members can only send transactions to the sync domain topology manager. The participant then sends an initial set of topology transactions required to identify the participant and define the keys used by the participant to the `DomainTopologyManagerRequestService`. The request service inspects the validity of the transactions and decides based on the configured sync domain on-boarding policy. The currently supported policies are `open` (default) and `permissioned`. While `open` is convenient for permissionless systems and for development, it will accept any new participant and any topology transaction. The `permissioned` policy will accept the participant's onboarding transactions only if the participant has been added to the allow-list beforehand.
8. The request service forwards the transactions to the sync domain topology manager, which attempts to add them to the state (and thus trigger the distribution to the other members on a sync domain). The result of the onboarding request is sent to the unauthenticated member

who disconnects upon receiving the response.

9. If the onboarding request is approved, the participant now attempts to connect to the sequencer as the actual participant.
10. Once the participant is properly enabled on the sync domain and its signing key is known, the participant can subscribe to the `SequencerService` with its identity. To do that and to verify the authorization of any action on the `SequencerService`, the participant must obtain an authorization token from the sync domain. For this purpose, the participant requests a `Challenge` from the sync domain. The sync domain will provide it with a `nonce` and the fingerprint of the key to be used for authentication. The participant signs this nonce (together with the sync domain ID) using the corresponding private key. The reason for the fingerprint is simple: the participant needs to sign the token using the participant's signing key as defined by the sync domain topology state. However, as the participant will learn the true sync domain topology state only by reading from the `SequencerService`, it cannot know what the key is. Therefore, the sync domain discloses this part of the sync domain topology state as part of the authorization challenge.
11. Using the created authentication token, the participant starts to use the `SequencerService`. On the sync domain side, the sync domain verifies the authenticity and validity of the token by verifying that the token is the expected one and is signed by the participant's signing key. The token is used to authenticate every GRPC invocation and needs to be renewed regularly.
12. The participant sets up the `ParticipantTopologyDispatcher`, which is the process that tries to push all topology transactions created at the participant node's topology manager to the sync domain topology manager. If the participant is using its topology manager to manage its identity on its own, these transactions contain all the information about the registered parties or supported packages.
13. As mentioned above, the first set of messages received by the participant through the sequencer contains the sync domain topology state, which includes the signing keys of the sync domain entities. These messages are signed by the sequencer and topology manager and are self-consistent. If the participants know the sync domain ID, they can verify that they are talking to the expected sync domain and that the keys of the sync domain entities have been authorized by the owner of the key governing the sync domain ID.
14. Once the initial topology transactions have been read, the participant is ready to process transactions and send commands.
15. When a participant is (re-)enabled, the sync domain topology dispatcher analyses the set of topology transactions the participant has missed before. It sends these transactions to the participant via the sequencer, before publicly enabling the participant. Therefore, when the participant starts to read messages from the sequencer, the initially received messages will be the topology state of the sync domain.

31.1.7 Default Initialization

The default initialization behavior of participant nodes and sync domains is to run their own topology manager. This provides a convenient, automatic way to configure the nodes and make them usable without manual intervention, but it can be turned off by setting the `auto-init = false` configuration option **before** the first startup.

During the auto initialization, the following steps occur:

1. On the sync domain, we generate four signing keys: one for the namespace and one each for the sequencer, mediator and topology manager. On the participant, we generate three keys: a namespace key, a signing key and an encryption key.
2. Using the fingerprint of the namespace, we generate the participant identity. For understandability, we use the node name used in the configuration file. This will change into a random

identifier for privacy reasons. Once we've generated it, we set it using the `set_id` admin-api call.

3. We create a root certificate as `NamespaceDelegation` using the namespace key, signing with the namespace key.
4. Then, we create an `OwnerToKeyMapping` for the participant or sync domain entities.

The `init.identity` object can be set to control the behavior of the auto initialization. For instance, it is possible to control the identifier name that will be given to the node during the initialization. There are 3 possible configurations:

1. Use the node name as the node identifier

```
canton.participants.participant1.init.identity.node-identifier.type = config
```

2. Explicitly set a name

```
canton.participants.participant1.init.identity.node-identifier.type = explicit
canton.participants.participant1.init.identity.node-identifier.name = MyName
```

3. Generate a random name

```
canton.participants.participant1.init.identity.node-identifier.type = random
```

31.1.8 Identity Setup Guide

As explained, Canton nodes auto-initialize by default, running their own topology managers. This is convenient for development and prototyping. Actual deployments require more care and therefore, this section should serve as a brief guideline.

Canton topology managers have one crucial task they must not fail at: do not lose access to or control of the root of trust (namespace keys). Any other key problem can somehow be recovered by revoking an old key and issuing a new owner to key association. Therefore, it is advisable that participants and parties are associated with a namespace managed by a topology manager that has sufficient operational setups to guarantee the security and integrity of the namespace.

Therefore, a participant or sync domain can

1. Run their own topology manager with their identity namespace key as part of the participant node.
2. Run their own topology manager on a detached computer in a self-built setup that exports topology transactions and transports them to the respective node (i.e. via burned CD roms).
3. Ask a trusted topology manager to issue a set of identifiers within the trusted topology manager's namespace as delegations and import the delegations to the local participant topology manager.
4. Let a trusted topology manager manage all the topology state on-behalf.

Obviously, there are more combinations and options possible, but these options here describe some common options with different security and recoverability options.

To reduce the risk of losing namespace keys, additional keys can be created and allowed to operate on a certain namespace. In fact, we recommend doing this and avoiding storing the root key on a live node.

31.2 User Identity Management

So far we have covered how on-ledger identities are managed.

Every participant also needs to manage access to their local Ledger API and be able to give applications permission to read or write to that API on behalf of parties. While an on-ledger identity is represented as a party, an application on the Ledger API is represented and managed as a user. A ledger API server manages applications' identities through:

- authentication: recognizing which user an application corresponds to (essentially by matching an application name with a user name)
- authorization: knowing which rights an authenticated user has and restricting their Ledger API access according to those rights

Authentication is based on JWT and covered in the [application development/authorization section](#) of the manual; the related Ledger API authorization configuration is covered in the [Ledger API JWT configuration section](#).

Authorization is managed by the Ledger API's User Management Service. In essence, a user is a mapping from a user name to a set of parties with read or write permissions. In more detail a user consists of:

- a user ID (also called user name)
- an active/deactivated status (can be used to temporarily ban a user from accessing the Ledger API)
- an optional primary party (indicates which party to use by default when submitting a Ledger API command request as this user)
- a set of user rights (describes whether a user has access to the admin portion of the Ledger API and what parties this user can act or read as)
- a set of custom annotations (string-based key-value pairs, stored locally on the Ledger API server, that can be used to attach extra information to this party, e.g. how it relates to some business entity)

All these properties except the user ID can be modified. To learn more about annotations refer to the [Ledger API Reference documentation](#). For an overview of the ledger API's UserManagementService, see this [section](#).

You can manage users through the [Canton console user management commands](#), an alpha feature. See the cookbook below for some concrete examples of how to manage users.

31.3 Cookbook

31.3.1 Manage Users

In this section, we present how you can manage participant users using the Canton console commands. First, we create three parties that we'll use in subsequent examples:

```
@ val Seq(alice, bob, eve) = Seq("alice", "bob", "eve").map(p => participant1.  
  ↪ parties.enable(name = p, waitForDomain = DomainChoice.All))  
Seq(alice, bob, eve) : Seq[PartyId] = List(alice::12207c217ee5...,  
  ↪ bob::12207c217ee5..., eve::12207c217ee5...)
```

31.3.1.1 Create

Next, create a user called `myuser` with `act-as` `alice` and `read-as` `bob` permissions and active user status. This user's primary party is `alice`. The user is not an administrator and has some custom annotations.

```
@ val user = participant1.ledger_api.users.create(id = "myuser", actAs =  
  ↳ Set(alice), readAs = Set(bob), primaryParty = Some(alice), participantAdmin =  
  ↳ false, isActive = true, annotations = Map("foo" -> "bar", "description" ->  
  ↳ "This is a description"))  
user : User = User(  
  id = "myuser",  
  primaryParty = Some(value = alice::12207c217ee5...),  
  isActive = true,  
  annotations = Map("foo" -> "bar", "description" -> "This is a description"),  
  identityProviderId = ""  
)
```

There are some restrictions on what constitutes a valid annotation key. In contrast, the only constraint for annotation values is that they must not be empty. To learn more about annotations refer to the [Ledger API Reference documentation](#).

31.3.1.2 Update

You can update a user's primary party, active/deactivated status and annotations. (You can also change what rights a user has, but using a different method presented further below.)

In the following snippet, you change the user's primary party to be unassigned, leave the active/deactivated status intact, and update the annotations. In the annotations, you change the value of the `description` key, remove the `foo` key and add the new `baz` key. The return value contains the updated state of the user:

```
@ val updatedUser = participant1.ledger_api.users.update(id = user.id, modifier =  
  ↳ user => { user.copy(primaryParty = None, annotations = user.annotations.updated(  
  ↳ "description", "This is a new description").removed("foo").updated("baz", "bar  
  ↳ ")}) })  
updatedUser : User = User(  
  id = "myuser",  
  primaryParty = None,  
  isActive = true,  
  annotations = Map("baz" -> "bar", "description" -> "This is a new description"),  
  identityProviderId = ""  
)
```

You can also update the user's identity provider ID. In the following snippets, you change the user's identity provider ID to the newly created one. Note that originally the user belonged to the default identity provider whose id is represented as the empty string `""`.

```
@ participant1.ledger_api.identity_provider_config.create("idp-id1",  
  ↳ isDeactivated = false, jwksUrl = "http://someurl", issuer = "issuer1", audience  
  ↳ = None)  
res4: com.digitalasset.canton.ledger.api.domain.IdentityProviderConfig =  
  ↳ IdentityProviderConfig(  
    identityProviderId = Id(value = "idp-id1"),
```

(continues on next page)

(continued from previous page)

```

isDeactivated = false,
jwksUrl = JwksUrl(value = "http://someurl"),
issuer = "issuer1",
audience = None
)

```

```

@ participant1.ledger_api.users.update_idp("myuser", sourceIdentityProviderId="",
↳targetIdentityProviderId="idp-id1")

```

```

@ participant1.ledger_api.users.get("myuser", identityProviderId="idp-id1")
res6: User = User(
  id = "myuser",
  primaryParty = None,
  isActive = true,
  annotations = Map("baz" -> "bar", "description" -> "This is a new description"),
  identityProviderId = "idp-id1"
)

```

You can change the user's identity provider ID back to the default one:

```

@ participant1.ledger_api.users.update_idp("myuser", sourceIdentityProviderId=
↳"idp-id1", targetIdentityProviderId="")

```

```

@ participant1.ledger_api.users.get("myuser", identityProviderId="")
res8: User = User(
  id = "myuser",
  primaryParty = None,
  isActive = true,
  annotations = Map("baz" -> "bar", "description" -> "This is a new description"),
  identityProviderId = ""
)

```

31.3.1.3 Inspect

You can fetch the current state of the user as follows:

```

@ participant1.ledger_api.users.get(user.id)
res9: User = User(
  id = "myuser",
  primaryParty = None,
  isActive = true,
  annotations = Map("baz" -> "bar", "description" -> "This is a new description"),
  identityProviderId = ""
)

```

You can query what rights a user has:

```

@ participant1.ledger_api.users.rights.list(user.id)
res10: UserRights = UserRights(
  actAs = Set(alice::12207c217ee5...),
  readAs = Set(bob::12207c217ee5...),
  participantAdmin = false,

```

(continues on next page)

(continued from previous page)

```
identityProviderAdmin = false
)
```

You can grant more rights. The returned value contains only newly granted rights; it does not contain rights the user already had even if you attempted to grant them again (like the read-as alice right in this example):

```
@ participant1.ledger_api.users.rights.grant(id = user.id, actAs = Set(alice,
↳ bob), readAs = Set(eve), participantAdmin = true)
res11: UserRights = UserRights(
  actAs = Set(bob::12207c217ee5...),
  readAs = Set(eve::12207c217ee5...),
  participantAdmin = true,
  identityProviderAdmin = false
)
```

You can revoke rights from the user. Again, the returned value contains only rights that were actually removed:

```
@ participant1.ledger_api.users.rights.revoke(id = user.id, actAs = Set(bob),
↳ readAs = Set(alice), participantAdmin = true)
res12: UserRights = UserRights(
  actAs = Set(bob::12207c217ee5...),
  readAs = Set(),
  participantAdmin = true,
  identityProviderAdmin = false
)
```

Now that you have granted and revoked some rights, you can fetch all of the user's rights again and see what they are:

```
@ participant1.ledger_api.users.rights.list(user.id)
res13: UserRights = UserRights(
  actAs = Set(alice::12207c217ee5...),
  readAs = Set(bob::12207c217ee5..., eve::12207c217ee5...),
  participantAdmin = false,
  identityProviderAdmin = false
)
```

Also, multiple users can be fetched at the same time. To do that, first create another user called myotheruser and then list all the users whose user name starts with my:

```
@ participant1.ledger_api.users.create(id = "myotheruser")
res14: User = User(
  id = "myotheruser",
  primaryParty = None,
  isActive = true,
  annotations = Map(),
  identityProviderId = ""
)
```

```
@ participant1.ledger_api.users.list(filterUser = "my")
res15: UsersPage = UsersPage(
  users = Vector(
```

(continues on next page)

(continued from previous page)

```

    User(
      id = "myotheruser",
      primaryParty = None,
      isActive = true,
      annotations = Map(),
      identityProviderId = ""
    ),
    User(
      id = "myuser",
      primaryParty = None,
      isActive = true,
      annotations = Map("baz" -> "bar", "description" -> "This is a new
↪description"),
      identityProviderId = ""
    )
  ),
  nextPageToken = ""
)

```

31.3.1.4 Decommission

You can delete a user by its ID:

```
@ participant1.ledger_api.users.delete("myotheruser")
```

You can confirm it has been removed by e.g. listing it:

```
@ participant1.ledger_api.users.list("myotheruser")
res17: UsersPage = UsersPage(users = Vector(), nextPageToken = "")
```

If you want to prevent a user from accessing the ledger API it may be better to deactivate it rather than deleting it. A deleted user can be recreated as if it never existed in the first place, while a deactivated user must be explicitly reactivated to be able to access the ledger API again.

```

@ participant1.ledger_api.users.update("myuser", user => user.copy(isActive =
↪false))
res18: User = User(
  id = "myuser",
  primaryParty = None,
  isActive = false,
  annotations = Map("baz" -> "bar", "description" -> "This is a new description"),
  identityProviderId = ""
)

```

31.3.1.5 Configure a default Participant Admin

Fresh participant nodes come with a default participant admin user called `participant_admin`, which can be used to bootstrap other users. You might prefer to have an admin user with a different user ID ready on a participant startup. For such situations, you can specify an additional participant admin user with the user ID of your choice.

Note: If a user with the specified ID already exists, then no additional user will be created, even if the preexisting user was not an admin user.

Listing 1: `additional-admin.conf`

```
canton.participants.myparticipant.ledger-api.user-management-service.additional-
  ↪admin-user-id = "my-admin-id"
```

31.3.2 Adding a new Party to a Participant

The simplest operation is adding a new party to a participant. For this, we add it normally at the topology manager of the participant, which in the default case is part of the participant node. There is a simple macro to enable the party on a given participant if the participant is running their own topology manager:

```
val name = "Gottlieb"
participant1.parties.enable(name)
```

This will create a new party in the namespace of the participant's topology manager.

And there is the corresponding disable macro:

```
participant1.parties.disable(name)
```

The macros themselves just use `topology.party_to_participant_mappings.authorize` to create the new party, but add some convenience such as automatically determining the parameters for the `authorize` call.

Note: Please note that the `participant.parties.enable` macro will add the parties to the same namespace as the participant is in. It only works if the participant has authority over that namespace either by possessing the root or a delegated key.

31.3.3 Client Controlled Party

Parties are only weakly tied to participant nodes. They can be allocated in their own namespace and then delegated to a given participant. For simplicity and convenience, the participant creates new parties in its own namespace by default, but there are situations where this is not desired.

A common scenario is that you first host the party on behalf of your client, but subsequently hand over the party to the client's node. With the default party allocation, you would still control the party of the client.

To avoid this, you need your client to create a new party on their own and export a party delegation to you. This party delegation can then be imported into your topology state, which will then allow you to act on behalf of the party.

For this process, we use a participant node which won't be connected to any sync domain. We don't need the full node, but just the topology manager. First, we need to find out the participant ID of the hosting node:

```
@ hosting.id.toProtoPrimitive
res1: String =
  ↪"PAR::participant2::12208b328119fc18018363b3c7bb05030d065e62798138eb5c3a95758106e3f47608
  ↪"
```

This identifier needs to be communicated to the client and can be imported using `ParticipantId.tryFromProtoPrimitive`. The client then creates first a new key (they could use the default key created):

```
@ val secret = client.keys.secret.generate_signing_key("my-party-key")
secret : SigningPublicKey = SigningPublicKey(id = 1220473d66a4..., format = Tink,
  ↪scheme = Ed25519)
```

and an appropriate root certificate for this key:

```
@ val rootCert = client.topology.namespace_delegations.authorize(TopologyChangeOp.
  ↪Add, secret.fingerprint, secret.fingerprint, isRootDelegation = true)
rootCert : com.google.protobuf.ByteString = <ByteString@fe55d51 size=652 contents=
  ↪"\n\211\005\n\267\002\n\262\002\n\257\002\022 kjVWQMIUD144SDdPUFnEVSzgpCR4RmHK\
  ↪032...">
```

This root certificate needs to be exported into a file:

```
@ import com.digitalasset.canton.util.BinaryFileUtil
```

```
@ BinaryFileUtil.writeByteStringToFile("rootCert.bin", rootCert)
```

Define the party ID of the party you want to create:

```
@ val partyId = PartyId("Client", secret.fingerprint)
partyId : PartyId = Client::1220473d66a4...
```

Create and export the party to participant delegation:

```
@ val partyDelegation = client.topology.party_to_participant_mappings.
  ↪authorize(TopologyChangeOp.Add, partyId, hostingNodeId, RequestSide.From)
partyDelegation : com.google.protobuf.ByteString = <ByteString@7f4e9fc4 size=557
  ↪contents="\n\252\004\n\330\001\n\323\001\n\320\001\022
  ↪igreHbtpv6BDF0Su2oAypIMceopnylab2...">
```

```
@ BinaryFileUtil.writeByteStringToFile("partyDelegation.bin", partyDelegation)
```

The client now shares the `rootCert.bin` and `partyDelegation.bin` files with the hosting node. The hosting node imports them into their topology state:

```
@ hosting.topology.load_transaction(BinaryFileUtil.tryReadByteStringFromFile(
  ↪"rootCert.bin"))
```

```
@ hosting.topology.load_transaction(BinaryFileUtil.tryReadByteStringFromFile(
  ↪ "partyDelegation.bin"))
```

Finally, the hosting node needs to issue the corresponding topology transaction to enable the party on its node:

```
@ hosting.topology.party_to_participant_mappings.authorize(TopologyChangeOp.Add,
  ↪ partyId, hosting.id, RequestSide.To)
res11: com.google.protobuf.ByteString = <ByteString@86beafa size=557 contents="\n\
  ↪ 252\004\n\330\001\n\323\001\n\320\001\022 3HIJxEWANAPJomHBufpo07WbE2elvwgG2...">
```

An alternative method would be to issue an identifier delegation certificate to a key controlled by the hosting node. In this case, the party wouldn't be delegated to a specific participant. Instead, the unique identifier would be delegated to a specific key, which would then in turn be able to delegate the party to a participant.

31.3.4 Replicate Party to Another Participant Node

Important: [Daml Enterprise license](#) required

Note:

The improved macros are available in Daml Enterprise 2.x as of release 2.8.1.

In 2.x, party migration has limitations. Please read the documentation carefully.

The macros work with protocol version 4 or later.

The involved participants must be entirely quiet during the migration. Therefore, the migration can only happen during a maintenance window of the sync domain where the rate is set to 0.

The target participant must not know about any contract involving the party prior to the migration.

The weak coupling of parties to participants allows you to migrate parties together with their active contract set from one participant node to another. The process described below uses a specific set of commands that have to be executed in the right order with some care.

We assume that there are three participants: The `sourceParticipant` from which the existing contract set will be copied, a `targetParticipant` to which the contract set will be copied, and a `controllingParticipant` that owns the party. In some cases, the controlling participant will be the same as the source participant, but this is not required.

Note: Please note that the entire system needs to be totally quiet for this process to succeed. You currently cannot migrate a party under load on 2.x. If you migrate a party on a system that processes transactions, the processing data will eventually become corrupt, breaking your node. The macros will refuse to run if the system is not idle. Therefore, follow the steps below carefully.

First, turn off transaction processing on the sync domain by setting the rate to 0 and wait for all timeouts to have elapsed (mediator & participant reaction timeout):

```
@ mydomain.service.set_max_rate_per_participant(0)
```

This is necessary as otherwise the contract set might change, or there might be inflight transactions and locked contracts which would confuse the newly onboarded participant.

Assuming there is a party named `Alice` permissioned on the `sourceParticipant`, you first download the active contract set of the party:

```
@ val alice = sourceParticipant.parties.find("Alice")
alice : PartyId = Alice::12208bb4be34...
```

```
@ repair.party_migration.step1_store_acs(sourceParticipant, Set(alice),
↳ partiesOffboarding = true, "alice.acs.gz")
```

This will store all the contracts in the file. If the file ends with `.gz`, then the content will be compressed. After transferring the file to the target participant, you first need to disconnect the target participant from the sync domain, because the repair service cannot run with an active sync domain connection:

```
@ targetParticipant.domains.disconnect_all()
```

Once disconnected, import the contracts using the next repair macro:

```
@ repair.party_migration.step2_import_acs(targetParticipant, Set(alice), "alice.
↳ acs.gz")
```

Although this step has imported the contracts, the party is still not enabled on the target participant. For a party to be delegated to a participant, both the owner of the party and the participant need to issue the required topology transactions. If the controlling participant is connected to the sync domain, you run the next step:

```
@ repair.party_migration.step3_delegate_party_to_target_
↳ node(controllingParticipant, Set(alice), targetParticipantId)
```

This will issue the party to participant topology transaction of type `From`. The `To` transaction must be issued on the `targetParticipant`, using the fourth step. The participant must be connected to the sync domain for this step:

```
@ targetParticipant.domains.reconnect_all()
```

```
@ repair.party_migration.step4_enable_party_on_target(targetParticipant,
↳ Set(alice))
```

After this step, the party is enabled on the target participant and the active contract set has been migrated, but the party is now hosted by both `sourceParticipant` and `targetParticipant`.

If you want to remove the party from the source participant, continue with the next step before resetting the sync domain rate back to its original value. First, unregister the party from the source participant:

```
@ repair.party_migration.step5_remove_party_delegation_from_
↳ source(controllingParticipant, Set(alice), sourceParticipant)
```

Then, disconnect the source participant from the sync domain:

```
@ sourceParticipant.domains.disconnect_all()
```

Finally, remove the active contracts of Alice from the source participant:

```
@ repair.party_migration.step6_cleanup_source(sourceParticipant, "alice.acs.gz",
↳ Set(alice))
```

Thereafter, reconnect to the sync domain and re-enable transaction processing on the sync domain:

```
@ sourceParticipant.domains.reconnect_all()
```

```
@ mydomain.service.set_max_rate_per_participant(10000)
```

31.3.5 Party on Multiple Nodes

Note: The below section is used to demonstrate the capabilities of Canton or to be helpful in special setups. Please use the repair macros as explained above to migrate parties between nodes. The below section contains commands that can break your system if used incorrectly.

Assuming we have party ("Alice", N1) which we want to host on two participants: ("participant1", N1) and ("participant2", N2). In this case, we have the party Alice in namespace N1, whereas the participant2 is in namespace N2. In order to set this up, we need to appropriately authorize the participants to act on behalf of the party. In this example, we assume that the party is added to both nodes at the same time before any contract is created. If you want to migrate an existing party, [follow the guide above](#).

To make sure that we don't accidentally create a contract that is observed by one node and not the others, set the sync domain rate to 0, which will ensure that no contracts can be created on the sync domain during this maintenance period:

```
@ mydomain.service.set_max_rate_per_participant(0)
```

Starting with a party allocated on participant1:

```
@ val alice = participant1.parties.enable("Alice")
alice : PartyId = Alice::1220221ab8c4...
```

To add this party to participant2, participant2 must first agree to host the party. This is done by authorizing the RequestSide.To of the party to participant mapping on the target participant:

```
@ participant2.topology.party_to_participant_mappings.authorize(TopologyChangeOp.
↳ Add, alice, participant2.id, RequestSide.To, ParticipantPermission.Submission)
res3: com.google.protobuf.ByteString = <ByteString@2a8ca4b7 size=554 contents="\n\
↳ 247\004\n\327\001\n\322\001\n\317\001\022 4WAa0XeBrlkWdmUnQL3LLYffpQWL7i6u2...">
```

The permission of the node can be restricted by setting the appropriate ParticipantPermission in the authorization call to either Observation or Confirmation instead of the default Submission. This allows setups where a party is hosted with Submission permissions on one node and Confirmation on another to increase the liveness of the party.

Note: The distinction between `Submission` and `Confirmation` is only enforced in the participant node. A malicious participant node with `Confirmation` permission for a certain party can submit transactions in the name of the party. This is due to Canton's high level of privacy where validators do not know the identity of the submitting participant. Therefore, a party who delegates `Confirmation` permissions to a participant should trust the participant sufficiently.

Next, add the `RequestSide.From` transaction such that the party is activated on the target participant:

```
@ participant1.topology.party_to_participant_mappings.authorize(TopologyChangeOp.  
  ↪Add, alice, participant2.id, RequestSide.From, ParticipantPermission.Submission)  
res4: com.google.protobuf.ByteString = <ByteString@3145184f size=556 contents="\n\  
  ↪251\004\n\327\001\n\322\001\n\317\001\022 ZQhW00TABtD1DhgSLcRuCoN2oioqior02...">
```

Check that the party is now hosted by two participants:

```
@ participant1.parties.list("Alice")  
res5: Seq[ListPartiesResult] = Vector(  
  ListPartiesResult(  
    party = Alice::1220221ab8c4...,  
    participants = Vector(  
      ParticipantDomains(  
        participant = PAR::participant2::1220312ced2e...,  
        domains = Vector(  
          DomainPermission(domain = mydomain::12205eccc907..., permission =  
↪Submission)  
        )  
      ),  
      ParticipantDomains(  
        participant = PAR::participant1::1220221ab8c4...,  
        domains = Vector(  
          DomainPermission(domain = mydomain::12205eccc907..., permission =  
↪Submission)  
        )  
      )  
    )  
  )  
)
```

Finally, the transaction processing on the sync domain can be re-enabled again:

```
@ mydomain.service.set_max_rate_per_participant(100)
```

Both participants will now see the same contracts, and depending on the permissions, be able to submit on behalf of the party. Each hosting participant will be included in the transaction, which means that there is an upper limit on where this feature is useful. If you need to share contract data with many participants, you should consider using explicit disclosure and sharing contract data out of band.

Chapter 32

Common Operational Tasks

32.1 Manage DARs and Packages

A package is a unit of compiled Daml code corresponding to one Daml project. A DAR is a collection of packages including a main package and all other packages from the dependencies of this Daml project.

32.1.1 Uploading DARs

To use a Daml application on a participant, you need to upload it to your participant node. The application always comes packaged as one or more DARs that need to be uploaded in the order of their dependency. There are two ways to upload DARs to a Canton node: either via the [Ledger Api](#), or through Canton [console command](#):

```
@ participant2.dars.upload("dars/CantonExamples.dar")
res1: String =
↪ "12202102be83f3489f0f3df0d42d54280e6769eb173a8fee8eb02b20f82e1ef5d709"
```

32.1.2 Inspecting DARs and Packages

You can get a list of uploaded DARs using:

```
@ participant2.dars.list()
res2: Seq[com.digitalasset.canton.participant.admin.v0.DarDescription] = Vector(
  DarDescription(
    hash = "12207f38b04c40dd9cf5bc1daa97625427665af959801fc77024dafd5898cb01f01b",
    name = "AdminWorkflowsWithVacuuming"
  ),
  DarDescription(
    hash = "12202102be83f3489f0f3df0d42d54280e6769eb173a8fee8eb02b20f82e1ef5d709",
    name = "CantonExamples"
  )
)
```

Please note that the package `AdminWorkflows` is a package that ships with Canton. It contains the Daml templates used by the `participant.health.ping` command.

In order to inspect the contents of the DAR, you need to grab the hash identifying it:

```
@ val dars = participant2.dars.list(filterName = "CantonExamples")
dars : Seq[com.digitalasset.canton.participant.admin.v0.DarDescription] = Vector(
  DarDescription(
    hash = "12202102be83f3489f0f3df0d42d54280e6769eb173a8fee8eb02b20f82e1ef5d709",
    name = "CantonExamples"
  )
)
```

```
@ val hash = dars.head.hash
hash : String =
  ↪ "12202102be83f3489f0f3df0d42d54280e6769eb173a8fee8eb02b20f82e1ef5d709"
```

Using that hash, you can inspect the contents of the DAR using:

```
@ val darContent = participant2.dars.list_contents(hash)
darContent : DarMetadata = DarMetadata(
  name = "CantonExamples",
  main = "7e0aa3d819f2dfd20c1ba08ac133130e1f135172e5c0f4cf0c8a70d79d7b5a84",
  packages = Vector(
    "7e0aa3d819f2dfd20c1ba08ac133130e1f135172e5c0f4cf0c8a70d79d7b5a84",
    "6851f194e144b693e63e9034b956c76cef6b5088dd8c66a657ab652a204dba2b",
    "cb0552debf219cc909f51cbb5c3b41e9981d39f8f645b1f35e2ef5be2e0b858a",
    "3f4deaf145a15cdcf762c058005e2edb9baa75bb7f95a4f8f6f937378e86415",
    ..
  )
)
```

You can also directly look at the packages, using:

```
@ participant2.packages.list()
res6: Seq[com.digitalasset.canton.participant.admin.v0.PackageDescription] = ↪
  ↪ Vector(
    PackageDescription(
      packageId = "88cf65277201722eda8564ac04494bed23ac79673722af482c6f3fb37aec83ed
      ↪ ",
      sourceDescription = "AdminWorkflowsWithVacuuming"
    ),
    PackageDescription(
      packageId = "86828b9843465f419db1ef8a8ee741d1eef645df02375ebf509cdc8c3ddd16cb
      ↪ ",
      sourceDescription = "CantonExamples"
    ),
    ..
  )
)
```

Please note that a DAR can include packages that are already included in other DARs. In particular the Daml standard library is shipped with every DAR. Therefore, the `sourceDescription` will always contain only one textual reference to a DAR.

You can also inspect the content of a package, using:

```
@ participant2.packages.list_contents(darContent.main)
res7: Seq[com.digitalasset.canton.participant.admin.v0.ModuleDescription] = ↪
  ↪ Vector(
    ModuleDescription(name = "CantonExamples"),
    ModuleDescription(name = "ContractKeys"),
    ModuleDescription(name = "SafePaint"),
    ModuleDescription(name = "LockIou"),
    ..
  )
)
```

(continues on next page)

(continued from previous page)

```
ModuleDescription(name = "Iou"),
ModuleDescription(name = "Divulgence"),
ModuleDescription(name = "Paint"),
..
```

32.1.3 Understanding Package Vetting

Every participant operator uploads DARs individually to their participant node. There is no global DAR repository anywhere and participants do not have access to each others DAR repositories. Instead, participants publicly declare towards their peers that they are ready to receive transactions referring to certain packages. This is done by Canton package state topology transactions which can be seen by all the participants connected to a specific sync domain. Therefore, for two participants to synchronize a transaction that uses packages contained in a certain DAR, both participant operators must upload and vet the same DAR and its contained packages before the transaction is submitted.

If the DAR has not been uploaded to one of the involved participants or it has not been vetted, then transaction submissions are rejected with a `NO_DOMAIN_FOR_SUBMISSION` error (with additional metadata listing which package has not been vetted on which participant).

Transactions are valid only if all involved participants have vetted the used packages. This helps prohibiting attacks from malicious participants, who could send a transaction referring to a package the receiver does not have. Such a transaction would be impossible for the receiver to process, leading to a ledger fork.

32.1.3.1 DAR vetting lifecycle

As mentioned above, a participant can start accepting transactions that reference packages in a DAR after it has been uploaded and vetted.

Vetting happens automatically when you upload a DAR, although it can be disabled by a request flag.

```
@ val darHash = participant1.dars.upload("dars/CantonExamples.dar", □
  ↪ vetAllPackages = false)
darHash : String =
  ↪ "12202102be83f3489f0f3df0d42d54280e6769eb173a8fee8eb02b20f82e1ef5d709"
```

The packages contained in a DAR can also be vetted explicitly when the DAR upload operation was performed without vetting

```
@ participant1.dars.vetting.enable(darHash)
```

After uploading and vetting, you can create a contract referencing a template from the main package of the DAR:

```
@ val mainPackageId = participant1.packages.find("Iou").head.packageId
mainPackageId : String =
  ↪ "7e0aa3d819f2dfd20c1ba08ac133130e1f135172e5c0f4cf0c8a70d79d7b5a84"
```

```
@ participant1.domains.connect_local(mydomain)
```

```
@ val createIouCmd = ledger_api_utils.create(mainPackageId, "Iou", "Iou", Map("payer"
→ " -> participant1.adminParty, "owner" -> participant1.adminParty, "amount" -> Map(
→ "value" -> 100.0, "currency" -> "EUR"), "viewers" -> List()))
..
```

```
@ participant1.ledger_api.commands.submit(Seq(participant1.adminParty ), □
→ Seq(createIouCmd))
res13: com.daml.ledger.api.v1.transaction.TransactionTree = TransactionTree(
  transactionId =
→ "1220659388dfd31751452e0af913535d8c26e9176e0caf23185fd7b7f825276bb1e6",
  commandId = "bb2732c7-64d4-4fec-8696-d491b1574206",
  workflowId = "",
  effectiveAt = Some(
..
```

You can unvet a DAR, effectively preventing its use in Daml transactions.

```
@ participant1.dars.vetting.disable(darHash)
```

Note: Unvetting a DAR is a supported and safe operation on participants running protocol version 7 and above. Usage of this operation in production environments is not advised on previous protocol versions.

Any subsequent commands attempting to create or exercise choices on contracts for the referenced package IDs are rejected.

```
@ participant1.ledger_api.commands.submit(Seq(participant1.adminParty), □
→ Seq(createIouCmd))
ERROR com.digitalasset.canton.integration.EnterpriseEnvironmentDefinition$$anon$3 □
→ - Request failed for participant1.
  GrpcRequestRefusedByServer: FAILED_PRECONDITION/NO_DOMAIN_FOR_SUBMISSION(9,
→ 67d333be): No valid domain for submission found.
  Request: SubmitAndWaitTransactionTree(
    actAs = participant1::1220c1317037...,
    readAs = Seq(),
    commandId = '',
    workflowId = '',
    submissionId = '',
    deduplicationPeriod = None(),
    applicationId = 'CantonConsole',
    commands = ...
  )
  CorrelationId: 67d333bed94be4929c64661a19003178
  Context: HashMap(participant -> participant1, test -> □
→ PackageDarManagementDocumentationIntegrationTest, domainsNotUsed -> □
→ Map(mydomain::12202c2a92d4... -> The topology state for some packages does not □
→ meet the requirements on domain mydomain::12202c2a92d4...: [(Participant □
→ PAR::participant1::1220c1317037... has not vetted 7e0aa3d819f2...)]), tid -> □
→ 67d333bed94be4929c64661a19003178, definite_answer -> false)
  Command BaseLedgerApiAdministration$ledger_api$commands$.submit invoked from □
→ cmd10000036.sc:1
```

If the decision to support the DAR changes, it can be re-vetted:

```
@ participant1.dars.vetting.enable(darHash)
```

```
@ participant1.ledger_api.commands.submit(Seq(participant1.adminParty),
  ↳ Seq(createIouCmd))
res16: com.daml.ledger.api.v1.transaction.TransactionTree = TransactionTree(
  transactionId =
  ↳ "1220f808522edffc3410e69d2aa48eb299f3a345995b0951a1a522251bc205efec6a",
  commandId = "ff9298e6-b78c-4ba6-8f18-c65779a58457",
  workflowId = "",
  effectiveAt = Some(
  ..
```

What if a package is vetted multiple times?

You can't unvet a DAR whose main package is referenced from another vetted DAR. For example, if you upload a DAR that depends on the `CantonExamples` DAR and try to unvet the latter, the operation fails

```
@ val examplesDependencyDarHash = participant1.dars.upload("dars/
  ↳ CantonExamplesDependency.dar")
examplesDependencyDarHash : String =
  ↳ "1220ee0bfbe921a7f88b376b9b35c74d9ff18a4aab9ceacf877b8e1880281518ef7a"
```

```
@ participant1.dars.vetting.disable(darHash)
ERROR com.digitalasset.canton.integration.EnterpriseEnvironmentDefinition$$anon$3
  ↳ - Request failed for participant1.
    GrpcRequestRefusedByServer: FAILED_PRECONDITION/MAIN_DAR_PACKAGE_REFERENCED_
  ↳ EXTERNALLY(9,e170807f): Operation DAR disabling for DAR 'CantonExamples' failed
  ↳ due to its main package with
  ↳ packageId=7e0aa3d819f2dfd20c1ba08ac133130e1f135172e5c0f4cf0c8a70d79d7b5a84
  ↳ being vetted multiple times
    Request:
  ↳ UnvetDar(12202102be83f3489f0f3df0d42d54280e6769eb173a8fee8eb02b20f82e1ef5d709,
  ↳ true)
    CorrelationId: e170807f92749b94aa7a5c8a552a4804
    Context: HashMap(participant -> participant1, test ->
  ↳ PackageDarManagementDocumentationIntegrationTest, darDescription ->
  ↳ CantonExamples, operationName -> DAR disabling, mainPackageId ->
  ↳ 7e0aa3d819f2dfd20c1ba08ac133130e1f135172e5c0f4cf0c8a70d79d7b5a84, tid ->
  ↳ e170807f92749b94aa7a5c8a552a4804)
    Command ParticipantAdministration$dars$vetting$.disable invoked from
  ↳ cmd10000044.sc:1
```

Instead, you should first unvet the `CantonExamplesDependency` DAR, which contains as package dependencies the main package of the `CantonExamples` ,

```
@ participant1.dars.vetting.disable(examplesDependencyDarHash)
```

then you can safely unvet the `CantonExamples` DAR as well.

```
@ participant1.dars.vetting.disable(darHash)
```

32.1.3.2 Advanced vetting concepts

Note: This section concentrates on lower-level details of package topology state and commands. For most use cases, the high-level vetting APIs mentioned above are sufficient. Using lower-level topology APIs can lead to inconsistencies in the participant's topology state; it should be used only by experts.

Package topology states

With respect to a participant, a package can be in one of the following states:

Not found: The package does not exist in the local participant stores and cannot be referenced in any request to the participant node.

Unknown: The package may exist in the local participant stores, but it has no associated topology transaction issued by the participant node (i.e. it is unknown topology-wise). A package pertaining to a DAR uploaded with the vetting flag off is unknown.

Check-only: The package appears in a *CheckOnlyPackages* topology transaction and it allows a participant to announce that a collection of Daml packages is known, but it can only be used to validate preexisting contracts on the ledger, not for executing new Daml transactions (e.g. contract creates or exercises using Daml code defined in the package). This concept has been introduced in protocol version 7 to support [Smart contract upgrades](#).

Vetted: A package in this state appears at least in a *VettedPackages* topology transaction and allows the participant to accept new transactions that reference it in Daml action nodes. This state is unchanged from the previous protocol versions.

For a DAR that is unknown (topology-wise), the vetting operations (`participant.dars.vetting.enable(darHash)` or `PackageService.vetDar`) results in a *VettedPackages* topology transaction referencing all the packages in the DAR.

Note: The unit of Daml code for which a Canton participant can issue topology transactions is the Daml package. However, in practice, to ensure that transactions can be successfully submitted using any package of a specific DAR, the Canton vetting APIs act at the DAR level (i.e. for all of a DAR's packages, transactionally). The APIs in question are the console commands: `participant.dars.vetting.enable` and `participant.dars.vetting.disable` as well as the Admin API calls: `PackageService.vetDar` and `PackageService.unvetDar`.

To illustrate the point, please vet the example DAR again:

```
@ participant1.dars.vetting.enable(darHash)
```

Now, check that the DAR's main package-id appears in a *VettedPackages* topology transaction:

```
@ participant1.topology.vetted_packages.list().exists(_.item.packageIds.  
  ↪ contains(mainPackageId))  
res21: Boolean = true
```

Note: When a DAR is vetted, if it exists, the *CheckOnlyPackages* topology transaction is eventually removed, as a *VettedPackages* topology transaction already implies that the referenced packages can

be used for validating the preexisting ledger contracts. This operation is asynchronous and does not block the vetting API call.

Now, unvet the DAR:

```
@ participant1.dars.vetting.disable(darHash)
```

And you can observe that the package ID appears only in a *CheckOnlyPackages* topology transaction:

```
@ participant1.topology.vetted_packages.list().exists(_.item.packageIds.  
  ↳contains(mainPackageId))  
res23: Boolean = false
```

```
@ participant1.topology.check_only_packages.list().exists(_.item.packageIds.  
  ↳contains(mainPackageId))  
res24: Boolean = true
```

Commands toggling between the two vetting states effectively issue two topology operations:

On vetting enable: A *VettedPackages* topology transaction addition and the removal of the corresponding *CheckOnlyPackages* topology transaction

On vetting disable: A *CheckOnlyPackages* topology transaction addition and the removal of the *VettedPackages* topology transaction

Forcefully unvetting a package

In some cases, you might want to circumvent the high-level vetting APIs and directly issue or revoke package topology transactions. One such example is when a package is referenced in multiple topology transactions (e.g. the package is contained in multiple vetted DARs uploaded on the participant) and it cannot be automatically unvetted (as exemplified in the [What if a package is vetted multiple times?](#)).

To build the example, re-enable vetting for both the *CantonExamples* and the *CantonExamplesDependency* DARs.

```
@ participant1.dars.vetting.enable(examplesDependencyDarHash)
```

```
@ participant1.dars.vetting.enable(darHash)
```

To mark the main package of the *CantonExamples* DAR as check-only, remove it from all the *VettedPackages* topology transactions it appears in using the low-level topology management API.

First, identify the topology transactions containing the package to remove:

```
@ val txsContainingMainPackage = participant1.topology.vetted_packages.  
  ↳list(filterStore = "Authorized", filterParticipant = participant1.id.  
  ↳filterString).filter(_.item.packageIds.contains(mainPackageId))  
txsContainingMainPackage : Seq[ListVettedPackagesResult] = Vector(  
  ListVettedPackagesResult(  
    context = BaseResult(  
      domain = "Authorized",  
      validFrom = 2025-01-09T12:49:35.660209Z,  
      validUntil = None,
```

(continues on next page)

(continued from previous page)

```

    operation = Add,
    serialized = <ByteString@74635c96 size=2450 contents="\n\217\023\n\275\020\
↪n\270\020\n\265\020\022 pq2G2mKLZMB05jYDi6GljSDXTmuQ8FUfJ...">,
    signedBy = 1220c1317037...
  ),
  item = VettedPackages(
    participant = participant1::1220c1317037...,
    packages = Seq(
      28cf6c194d92...,
      7e0aa3d819f2...,
      6851f194e144...,
    )
  )
..

```

Then, replace the `VettedPackages` transactions with ones that do not refer to the main package.

```
@ import com.digitalasset.canton.LfPackageId
```

```

@ txsContainingMainPackage.foreach { tx => participant1.topology.vetted_packages.
↪authorize(TopologyChangeOp.Remove, participant1.id, tx.item.packageIds, force = □
↪true); participant1.topology.vetted_packages.authorize(TopologyChangeOp.Add,
↪participant1.id, tx.item.packageIds.filterNot(_ == mainPackageId), force = true) }

```

Ensure that the package becomes check-only by issuing a dedicated `CheckOnlyPackages` topology transaction.

```

@ participant1.topology.check_only_packages.authorize(TopologyChangeOp.Add, □
↪participant1.id, Seq(LfPackageId.assertFromString(mainPackageId)), force = true)
..

```

32.2 Upgrade To a New Release

This section covers the processes to upgrade Canton participant nodes and sync domains. Upgrading Daml applications is covered [elsewhere](#).

As elaborated in the [versioning guide](#), new features, improvements and fixes are released regularly. To benefit from these changes, the Canton-based system must be upgraded.

There are two key aspects that need to be addressed when upgrading a system:

[Upgrading the Canton binary](#) that is used to run a node.

[Upgrading the protocol version](#) that defines how nodes interact with each other.

Canton is a distributed system, where no single operator controls all nodes. Therefore, we must support the situation where nodes are upgraded individually, providing a safe upgrade mechanism that requires the minimal amount of synchronized actions within a network.

A Canton binary supports [multiple protocol versions](#), and new protocol versions are introduced in a backward-compatible way with a new binary (see [version table](#)). Therefore, any upgrade of a protocol used in a distributed Canton network is done by individually upgrading all binaries and subsequently changing the protocol version used among the nodes to the desired one.

The following is a general guide. Before upgrading to a specific version, please check the individual notes for each version.

This guide also assumes that the upgrade is a minor or a patch release. Major release upgrades might differ and will be covered separately if necessary.

Warning:**Upgrading requires care and preparation.**

Please back up your data before any upgrade.

Note that the [order of the backups](#) is important.

Please test your upgrade thoroughly before attempting to upgrade your production system.

Once a migration has started it cannot be aborted or rolled back.

If you encounter an issue, you must restore the old version using the backups.

32.2.1 Upgrade Canton Binary

A Canton node consists of one or more processes, where each process is defined by

A Java Virtual Machine application running a versioned JAR of Canton.

A set of configuration files describing the node that is being run.

An optional bootstrap script passed via `--bootstrap`, which runs on startup.

A database (with a specific schema), holding the data of the node.

To upgrade the node,

1. Replace the Canton binary (which contains the Canton JAR).
2. Test that the configuration files can still be parsed by the new process.
3. Test that the bootstrap script you are using is still working.
4. Upgrade the database schema.

Generally, all changes to configuration files should be backward compatible, and therefore not be affected by the upgrade process. In rare cases, there might be a minor change to the configuration file necessary in order to support the upgrade process. Sometimes, fixing a substantial bug might require a minor breaking change to the API. The same applies to Canton scripts.

The schema in the database is versioned and managed using [Flyway](#). Detecting and applying changes is done by Canton using that library. Understanding this background can be helpful to troubleshoot issues.

32.2.1.1 Preparation

First, please download the new Canton binary that you want to upgrade to and store it on the test system where you plan to test the upgrade process.

Then, obtain a recent backup of the database of the node and deploy it to a database server of your convenience, such that **you can test the upgrade process without affecting your production system**. While we extensively test the upgrade process ourselves, we cannot exclude the eventuality that you are using the system in a non-anticipated way. Testing is cumbersome, but breaking a production system is worse.

If you are upgrading a participant, then we suggest that you also use an in-memory sync domain which you can tear down after you have tested that the upgrade of the participant is working. You

might do that by adding a simple sync domain definition as a configuration mixin to your participant configuration.

Generally, if you are running a high-availability setup, please take all nodes offline before performing an upgrade. If the update requires a database migration (check the release notes), avoid running older and newer binaries in a replicated setup, as the two binaries might expect a different database layout.

You can upgrade the binaries of a microservice-based sync domain in any order, as long as you upgrade the binaries of nodes accessing the same database at the same time. For example, you could upgrade the binary of a replicated mediator node on one weekend and an active-active database sequencer on another weekend.

32.2.1.2 Back Up Your Database

Before you upgrade the database and binary, please ensure that you have backed up your data, such that you can roll back to the previous version in case of an issue. You can back up your data by cloning it. In Postgres, the command is:

```
CREATE DATABASE newdb WITH TEMPLATE originaldb OWNER dbuser;
```

When doing this, you need to change the database name and user name in above command to match your setup.

32.2.1.3 Test your Configuration

Test that the configuration still works

```
./bin/canton -v -c storage-for-upgrade-testing.conf -c mynode.conf --manual-start
```

Here, the files `storage-for-upgrade-testing.conf` and `mynode.conf` need to be adjusted to match your case.

If Canton starts and shows the command prompt of the console, then the configuration was parsed successfully.

Note: The command line option `--manual-start` prevents the node from starting up automatically, allowing you to migrate the database.

32.2.1.4 Migrating the Database

Canton does not perform a database migration automatically. Migrations must be forced. We recommend that you start Canton using the command line option `--manual-start` (see [above](#)) when upgrading to a new Canton binary version that requires a database migration.

If you start a node that requires a database migration, you will observe the following Flyway error:

```
@ participant.start()
ERROR com.digitalasset.canton.integration.EnterpriseEnvironmentDefinition$$anon$3
↳ failed to initialize participant: There are 7 pending migrations to get to
↳ database schema version 8. Currently on version 1.1. Please run `participant.db.
↳ migrate` to apply pending migrations
Command LocalParticipantReference.start invoked from cmd10000002.sc:1
```

The database schema definitions are versioned and hashed. This error informs us about the current database schema version and how many migrations need to be applied. This check runs at startup, so if the node starts, the migrations was successful.

We can now force the migration to a new schema using:

```
@ participant.db.migrate()
```

You can also [configure the migrations to be applied automatically](#). Please note that you need to ensure that the user account the node is using to access the database allows to change the database schema. How long the migration takes depends on the version of the binary (see migration notes), the size of the database and the performance of the database server.

We recommend cleaning up your database before you start your node. On Postgres, run

```
VACUUM FULL;
```

Otherwise, the restart may take a long time while the database is cleaning itself up.

Subsequently, you can successfully start the node

```
@ participant.start()
```

Please note that the procedure remains the same for all other types of nodes, with a participant node used here as an example.

32.2.1.5 Test Your Upgrade

Once your node is up and running, you can test it by running a ping. If you are testing the upgrade of your participant node, then you might want to connect to the test sync domain

```
@ testdomain.start()
```

```
@ participant.domains.connect_local(testdomain)
```

If you did the actual upgrade of the production instance, then you would just reconnect to the current sync domain before running the ping:

```
@ participant.domains.reconnect_all()
```

You can check that the sync domain is up and running using

```
@ participant.domains.list_connected()
res6: Seq[ListConnectedDomainsResult] = Vector(
  ListConnectedDomainsResult(
    domainAlias = Domain 'testdomain',
    domainId = testdomain::1220e34dcf9e...,
```

(continues on next page)

(continued from previous page)

```
    healthy = true
  )
)
```

Finally, you can ping the participant to see if the system is operational

```
@ participant.health.ping(participant)
res7: Duration = 472 milliseconds
```

The ping command creates two contracts between the admin parties, then exercises and archives them – providing an end-to-end test of ledger functionality.

32.2.1.6 Version Specific Notes

Upgrade to Release 2.10

Protocol Versions

The recommended protocol version is 7, which is introduced by the 2.10 release. 2.10 also supports protocol version 5, but certain new features (e.g., Smart Contract Upgrading) are only available in protocol version 7.

Note that protocol version 6 has been marked as deleted and should not be used. Protocol version 7 has been introduced as its stable replacement (see [here](#) for more information about protocol versions).

Protocol version should be set explicitly

Since the 2.9 release, you must set the protocol version explicitly.

To specify the protocol version for your sync domain:

```
myDomain {
  init.domain-parameters.protocol-version = 7
}
```

For a domain manager:

```
domainManager {
  init.domain-parameters.protocol-version = 7
}
```

Make sure all environments use the same protocol version: you should not use one protocol version in a test environment and another one in production.

If a protocol version is not provided, you receive an error message:

```
ERROR c.d.c.CantonEnterpriseApp$ - CONFIG_VALIDATION_ERROR(8,0): Failed to
  validate the configuration due to:
Protocol version is not defined for domain `mydomain`. Define protocol version at
  key `init.domain-parameters.protocol-version`...
```

Enabling Smart Contract Upgrades

As mentioned above, the protocol version must be set to 7 to use Smart Contract Upgrades. For existing systems, this requires a domain migration to protocol version 7 when rolling out the 2.10 Canton binary.

Beyond configuring the protocol version, there are additional Daml compilation and build steps described [elsewhere](#).

Upgrade to Release 2.9

Protocol Versions

The recommended protocol version is 5 (see [here](#) for more information about protocol versions).

Version 2.9 does not offer support for protocol versions 3 and 4. If your sync domain is running one of these protocol versions, upgrade as described [below](#).

Protocol version should be set explicitly

Until now, sync domains were configured to pick the latest protocol version by default. Since the protocol version is an important parameter of the sync domain, having this value set behind the scenes caused unwanted behavior.

You now must specify the protocol version for your sync domain:

```
myDomain {  
    init.domain-parameters.protocol-version = 5  
}
```

For a domain manager:

```
domainManager {  
    init.domain-parameters.protocol-version = 5  
}
```

Deactivated sync domain data cleanup

Version 2.9 adds a new repair command [participant.repair.purge_deactivated_domain](#) to delete data of a defunct domain.

Using this command is recommended for removing any remaining but unnecessary data from previous sync domains that were migrated using the [participant.repair.migrate_domain](#) command.

Note that the `migrate_domain` command in 2.9 now automatically removes such data, but only for the sync domain on which it has been invoked.

Paging in Party Management

The `ListKnownParties` method on the `PartyManagementService` now returns at most 10,000 results by default to avoid memory issues in participants that know more than 10,000 parties.

The `next_page_token` can be used to request the next page (see [request](#) and [response](#)).

Upgrade to Release 2.8

Version 2.8 extends the database schema. If you use the `migrate` and `start` feature, the database schema will be automatically updated. Otherwise, perform the manual database migration steps outlined in the [database migration steps](#).

Protocol versions 3 and 4 are deprecated

Protocol versions 3 and 4 are now marked as deprecated and will be removed in 2.9. Protocol version 5 should be preferred for any new deployment.

Configuration changes

KMS wrapper-key configuration value: The configuration value for the KMS wrapper-key now accepts a simple string. Update your configuration as follows:

```
crypto.private-key-store.encryption.wrapper-key-id = { str = "..."} # version 2.7
crypto.private-key-store.encryption.wrapper-key-id = "..." # version 2.8
```

Indexer Schema Migration and Cache Weight Configuration: Remove the following configuration lines related to the indexer and Ledger API server schema migration and cache weight:

```
participants.participant.parameters.ledger-api-server-parameters.indexer.schema-
↳migration-attempt-backoff
participants.participant.parameters.ledger-api-server-parameters.indexer.schema-
↳migration-attempts
participants.participant.ledger-api.max-event-cache-weight
participants.participant.ledger-api.max-contract-cache-weight
```

SQL Batching Parameter: The expert mode SQL batching parameter has been moved. Generally, we recommend not changing this parameter unless advised by support.

```
canton.participants.participant.parameters.stores.max-items-in-sql-clause #[]
↳version 2.7
canton.participants.participant.parameters.batching.max-items-in-sql-clause #[]
↳version 2.8
```

Breaking console commands

Key Management Commands: The `owner_to_key_mappings.rotate_key` command was changed to avoid unwanted key rotations. It now expects a node reference to perform additional checks.

Sync domain filtering in testing commands: To improve consistency and code safety, some testing console commands now expect an optional sync domain alias (rather than a plain sync domain alias). For example, the following call needs to be rewritten:

```
participant.testing.event_search("da") # version 2.7
participant.testing.event_search(Some("da")) # version 2.8
```

The impacted console commands are: `participant.testing.event_search` and `participant.testing.transaction_search`

Packaging

We have reverted the packaging change introduced in version 2.7.0; the Bouncy Castle JAR is now included back in the Canton JAR. However, users with Oracle JRE must explicitly add the Bouncy Castle library to the classpath when running Canton.

```
java -cp bcprov-jdk15on-1.70.jar:canton-with-drivers-2.8.0-all.jar com.
digitalasset.canton.CantonEnterpriseApp
```

Breaking Error Code

The error code `SEQUENCER_DELIVER_ERROR` is superseded by two new error codes: `SEQUENCER_SUBMISSION_REQUEST_MALFORMED` and `SEQUENCER_SUBMISSION_REQUEST_REFUSED`. Update your client applications code accordingly.

Deprecations

`SequencerConnection.addConnection` is deprecated. Use `SequencerConnection.addEndpoints` instead.

Upgrade to Release 2.7

Version 2.7 slightly extends the database schema. Therefore, you will have to perform the [database migration steps](#). Alternatively, you can enable the new `migrate` and `start` mode in Canton, which triggers an automatic update of the database schema when a new minor version is deployed. This mode can be enabled by setting the appropriate storage parameter:

```
canton.X.Y.storage.parameters.migrate-and-start = yes
```

To benefit from the new security features in protocol version 5, you must [upgrade the sync domain accordingly](#).

Activation of unsupported features

In order to activate unsupported features, you now need to explicitly enable *dev-version-support* on the sync domain (in addition to the non-standard config flag). More information can be found in the [documentation](#).

Breaking changes around console commands

Key rotation The command `keys.secret.rotate_wrapper_key` now returns a different error code. An `INVALID_WRAPPER_KEY_ID` error has been replaced by an `INVALID_KMS_KEY_ID` error.

Adding sequencer connection The configuration of the sequencer client has been updated to accommodate multiple sequencers and their endpoints: method `addConnection` has been renamed to `addEndpoints` to better reflect the fact that it modifies an endpoint for the sequencer.

Hence, the command to add a new sequencer connection to the mediator would be changed to:

```
mediator1.sequencer_connection.modifyConnections(  
    _.addEndpoints(SequencerAlias.Default, connection)  
)
```

Unique contract key deprecation

The `unique-contract-keys` parameters for both participant nodes and sync domains are now marked as deprecated. As of this release, the meaning and default value (`true`) remain unchanged. However, contract key uniqueness will not be available in the next major version, featuring multi-sync-domain connectivity. If you are already setting this key to `false` explicitly (preview), this behavior will be the default one after the configuration key is removed. If you don't explicitly set this value to `false`, you are encouraged to evaluate evolving your existing applications and services to avoid relying on this feature. You can read more on the topic in the [documentation](#).

Causality tracking

An obsolete early access feature to enable causality tracking, related to preview multi-sync-domain, was removed. If you enabled it, you need to remove the following config lines, as they will not compile anymore:

```
participants.participant.init.parameters.unsafe-enable-causality-tracking = true  
participants.participant.parameters.enable-causality-tracking = true
```

Besu and Fabric drivers

In order to allow for independent updates of the different components, we have moved the drivers into a separate jar, which needs to be loaded into a separate classpath. As a result, deployments that use Fabric or Besu need to additionally download the jar and place it in the appropriate directory. Please [consult the installation documentation](#) on how to obtain this additional jar.

Removal of `deploy_sequencer_contract`

The command `deploy_sequencer_contract` has been removed and exchanged with a deployment through genesis block in examples. The `deploy_sequencer_contract`, while convenient, is ill-suited for any production environment and can cause more damage than harm. The deployment of a sequencing contract should only happen once on the blockchain; however, adding deployment as part of the bootstrapping script would cause a redeployment each time bootstrapping is done.

Ledger API error codes

The error codes and metadata of gRPC errors returned as part of failed command interpretation from the Ledger API have been updated to include more information. Previously, most errors from the Daml engine would be given as either `GenericInterpretationError` or `InvalidArgumentInterpretationError`. They now all have their own codes and encode relevant information in the gRPC Status metadata. Specific error changes are as follows: * `GenericInterpretationError` (Code: `DAML_INTERPRETATION_ERROR`) with gRPC status `FAILED_PRECONDITION` is now split into:

`DisclosedContractKeyHashingError` (Code: `DISCLOSED_CONTRACT_KEY_HASHING_ERROR`) with gRPC status `FAILED_PRECONDITION`

`UnhandledException` (Code: `UNHANDLED_EXCEPTION`) with gRPC status `FAILED_PRECONDITION`

`InterpretationUserError` (Code: `INTERPRETATION_USER_ERROR`) with gRPC status `FAILED_PRECONDITION`

`TemplatePreconditionViolated` (Code: `TEMPLATE_PRECONDITION_VIOLATED`) with gRPC status `INVALID_ARGUMENT`

`InvalidArgumentInterpretationError` (Code: `DAML_INTERPRETER_INVALID_ARGUMENT`) with gRPC status `INVALID_ARGUMENT` is now split into:

- `CreateEmptyContractKeyMaintainers` (Code: `CREATE_EMPTY_CONTRACT_KEY_MAINTAINERS`) with gRPC status `INVALID_ARGUMENT`
- `FetchEmptyContractKeyMaintainers` (Code: `FETCH_EMPTY_CONTRACT_KEY_MAINTAINERS`) with gRPC status `INVALID_ARGUMENT`
- `WronglyTypedContract` (Code: `WRONGLY_TYPED_CONTRACT`) with gRPC status `FAILED_PRECONDITION`
- `ContractDoesNotImplementInterface` (Code: `CONTRACT_DOES_NOT_IMPLEMENT_INTERFACE`) with gRPC status `INVALID_ARGUMENT`
- `ContractDoesNotImplementRequiringInterface` (Code: `CONTRACT_DOES_NOT_IMPLEMENT_REQUIRING_INTERFACE`) with gRPC status `INVALID_ARGUMENT`
- `NonComparableValues` (Code: `NON_COMPARABLE_VALUES`) with gRPC status `INVALID_ARGUMENT`
- `ContractIdInContractKey` (Code: `CONTRACT_ID_IN_CONTRACT_KEY`) with gRPC status `INVALID_ARGUMENT`

- `ContractIdComparability` (Code: `CONTRACT_ID_COMPARABILITY`) with gRPC status `INVALID_ARGUMENT`
- `InterpretationDevError` (Code: `INTERPRETATION_DEV_ERROR`) with gRPC status `FAILED_PRECONDITION`

The `ContractKeyNotVisible` error (previously encapsulated by `GenericInterpretationError`) is now transformed into a `ContractKeyNotFound` to avoid information leaking.

Upgrade to Release 2.6

Version 2.6 changes the database schema used. Therefore, you must perform the database migration steps. Depending on the size of the database, this operation can take many hours. Vacuuming your database before starting your nodes helps avoid long startup times. Otherwise, the participant node can refuse to start due to extremely long initial database response times.

Upgrade to Release 2.5

Version 2.5 will slightly extend the database schema used. Therefore, you will have to perform the database migration steps.

Some configuration arguments have changed. While rewrite rules are in place for backward compatibility, we recommend that you test your configuration before upgrading and update the settings to avoid using deprecated flags.

IMPORTANT: Existing sync domains and sync domain managers need to be reconfigured to keep on working. It is important that before attempting the binary upgrade, you configure the currently used protocol version explicitly:

```
canton.domains.mydomain.init.domain-parameters.protocol-version = 3
```

Nodes persist the static sync domain parameters used during initialization now. Version 2.5 is the last version that will require this explicit configuration setting during upgrading.

If you started the sync domain node accidentally before changing your configuration, your participants won't be able to reconnect to the sync domain, as they will fail with a message like:

```
DOMAIN_PARAMETERS_CHANGED(9,d5dfa5ce): The sync domain parameters have changed
```

To recover from this, you need to force a reset of the stored static sync domain parameters using:

```
canton.domains.mydomain.init.domain-parameters.protocol-version = 3
canton.domains.mydomain.init.domain-parameters.reset-stored-static-config = yes
```

To benefit from protocol version 4, you will have to [upgrade the sync domain accordingly](#).

Upgrade to Release 2.4

Version 2.4 will slightly extend the database schema used. Therefore, you will have to perform the database migration steps.

There have been a few consistency improvements to some console commands. In particular, we have renamed a few of the arguments and changed some of their types. As we have included automatic conversion and the change only affects special arguments (mainly timeouts), your script should still work. However, we recommend that you test your scripts for compilation issues. Please check the detailed release notes on the specific changes and their impact.

There was no change to the protocol. Participants and sync domains running 2.3 can also run 2.4, as both versions use the same protocol version.

Upgrade to Release 2.3

Version 2.3 will slightly extend the database schema used. Therefore, you will have to perform the database migration steps.

Furthermore, the Canton binary with version 2.3 has introduced a new protocol version 3, and deprecated the previous protocol version 2. In order to keep a node operational that is using protocol version 2, you need to turn on support for the deprecated protocol version.

On the participant, you need to turn on support for deprecated protocols explicitly:

```
canton.participants.myparticipant.parameters.minimum-protocol-version = 2.0.0
```

The default settings have changed to use protocol 3, while existing sync domains run protocol 2. Therefore, if you upgrade the binary on sync domains and sync domain manager nodes, you need to explicitly set the protocol version as follows:

```
canton.domains.mydomain.init.domain-parameters.protocol-version = 2.0.0
```

You cannot upgrade the protocol of a deployed sync domain! You need to keep it running with the existing protocol. Please follow the protocol upgrade guide to learn how to introduce a new protocol version.

32.2.2 Change the Canton Protocol Version

The Canton protocol is defined by the semantics and the wire format used by the nodes to communicate to each other. In order to process transactions, all nodes must be able to understand and speak the same protocol.

Therefore, a new protocol can be introduced only once all nodes have been upgraded to a binary that can run the version.

32.2.2.1 Upgrade the Synchronization Domain to a new Protocol Version

A sync domain is tied to a protocol version. This protocol version is configured when the sync domain is initialized and cannot be changed afterward. Therefore, **you can not upgrade the protocol version of a sync domain**. Instead, you deploy a new sync domain side by side with the old sync domain process.

This applies to all sync domain services, be it sequencer, mediator, or topology manager.

With that, the protocol upgrade process boils down to:

1. **Deploy a new sync domain with the new protocol version**

Deploy a new sync domain and ensure that the new sync domain is using the desired protocol version.

Also make sure to use different databases (or at least different schemas in the same database) for the sync domain services (domain node, mediator, sequencer node, and topology manager), channel names, smart contract addresses, etc.

The new sync domain must be completely separate, but you can reuse your DLT backend as long as you use different sequencer contract addresses or Fabric channels.

2. **Carry out a hard sync domain migration**

Instruct the participants individually using the [hard sync domain migration](#) to use the new sync domain.

Note: Currently, the sync domain ID cannot be preserved during upgrades.

Note: To use the same database with different schemas for the old and the new sync domains, set the `currentSchema` either in the JDBC URL or as a parameter in `storage.config.properties`.

32.2.2.2 Hard Synchronization Domain Migration

Warning: Ensure that you have appropriate backups in place and have tested this procedure before applying it to your production system.

A hard sync domain migration is performed using the [respective migration command](#).

You must enable this command using a special config switch:

```
canton.features.enable-repair-commands=yes
```

Assuming that you have several participants all connected to a sync domain named `olddomain`, ensure that there are no pending transactions. You can do that by either controlling your applications, or by [setting the resource limits](#) to 0 on all participants:

```
@ participant.resources.set_resource_limits(ResourceLimits(Some(0), Some(0)))
```

This rejects any new command and finishes processing the pending commands. Once you are sure that your participant node is idle, disconnect the participant node from the old sync domain:

```
@ participant.domains.disconnect("olddomain")
```

Test that the participant is disconnected from the sync domain by checking the list of active connections:

```
@ participant.domains.list_connected()
res3: Seq[ListConnectedDomainsResult] = Vector()
```

This is a good time to perform a backup of the database before proceeding:

```
CREATE DATABASE newdb WITH TEMPLATE originaldb OWNER dbuser;
```

Warning: Following steps modify the participant's data storage. Without a database backup for your participant, a potential recovery becomes significantly more difficult.

Next, we want to run the migration step. For this, we need to run the `repair.migrate_domain` command. The command expects two input arguments: The alias of the source sync domain and a sync domain connection configuration for the new sync domain.

In order to build a sync domain connection config, we can just type

```
@ val config = DomainConnectionConfig("newdomain", GrpcSequencerConnection.
  →tryCreate("https://127.0.0.1:5018"))
config : DomainConnectionConfig = DomainConnectionConfig(
  domain = Domain 'newdomain',
  sequencerConnections = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(
    endpoints = https://127.0.0.1:5018,
    transportSecurity = true
  ..
```

where the URL should point to the correct sync domain. If you are testing the upgrade process locally in a single Canton process using a target sync domain named `newdomain` (which is what we are doing in this example), you can grab the connection details using

```
@ val config = DomainConnectionConfig("newdomain", newdomain.sequencerConnection)
config : DomainConnectionConfig = DomainConnectionConfig(
  domain = Domain 'newdomain',
  sequencerConnections = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(
    endpoints = http://127.0.0.1:30258,
    transportSecurity = false
  ..
```

Now, using this configuration object, we can trigger the hard sync domain connection migration using

```
@ participant.repair.migrate_domain("olddomain", config)
```

This command registers the new sync domain and re-associate the contracts tied to `olddomain` to the new sync domain. In addition, some data specific to the old domain is automatically deleted.

Once all participants have performed the migration, they can reconnect to the sync domain:

```
@ participant.domains.reconnect_all()
```

Now, the new sync domain should be connected:

```
@ participant.domains.list_connected()
res8: Seq[ListConnectedDomainsResult] = Vector(
  ListConnectedDomainsResult(
    domainAlias = Domain 'newdomain',
    domainId = newdomain::1220ce2bad62...,
    healthy = true
  )
)
```

As we've previously set the resource limits to 0, we need to reset this back:

```
@ participant.resources.set_resource_limits(ResourceLimits(None, None))
```

Finally, we can test that the participant can process a transaction by running a ping on the new sync domain:

```
@ participant.health.ping(participant)
res10: Duration = 484 milliseconds
```

Note: Currently, the hard migration is the only supported way to migrate a production system. This is because unique contract keys are restricted to a single sync domain.

While the sync domain migration command is mainly used for upgrading, it can also be used to recover contracts associated with a broken sync domain.

After the upgrade, the participants may report a mismatch between commitments during the first commitment exchange, as they might have performed the migration at slightly different times. The warning should eventually stop once all participants are back up and connected.

Expected Performance

Performance-wise, we can note the following: when we migrate contracts, we write directly into the respective event logs. This means that on the source sync domain, we insert a transfer-out, while we write a transfer-in and the contract into the target sync domain. Writing this information is substantially faster than any kind of transaction processing (several thousand migrations per second on a single CPU/16-core test server). However, with very large datasets, the process can still take quite some time. Therefore, we advise you to measure the time the migration takes during the upgrade test to understand the necessary downtime required for the migration.

Furthermore, upon reconnecting, the participant needs to recompute the new set of commitments. This can take a while for large numbers of contracts.

32.2.3 One-Step Migration

The term *one-step migration* refers to upgrading the Canton binary version and the protocol version with a unified multi-step recipe.

One-step migration covers a [binary upgrade](#) from Canton version 2.3 and following minor versions up to a new minor release version. Additionally, it [changes the protocol version](#) supported by these prior releases to a protocol version supported by this new minor release version (see also the [protocol version table](#)).

Note: There is no need for a one-step migration when upgrading from one release version to another, as long as both [release versions support the protocol version](#) that your current sync domain uses. Follow the steps for [upgrading the Canton binary](#) instead.

Warning: Every upgrade requires specific and thorough testing before applying it to a particular production environment. Even though the one-step migration process has been tested through automatic and manual tests, and its steps are known to work, additional measures and configuration may be required to address the peculiarities of your environment.

32.2.3.1 One-Step Migration Recipe for 2.10

This recipe allows you to upgrade the Canton binary to release version 2.10 and migrate your sync domain to a new sync domain running protocol version 7.

Note: Version 2.10 supports protocol versions 5 and 7. Protocol version 7 is recommended and specified in the instructions. However, you can use the same instructions to migrate to a new sync domain running protocol version 5, if so desired.

The outlined recipe steps have been validated through automated tests to migrate from a sync domain running on release [2.3](#), [2.4](#), [2.5](#), [2.6](#), [2.7](#), [2.8](#), or [2.9](#) and protocol version 3, 4, or 5 to a new sync domain running on release 2.10 and protocol version 5 or 7.

Note: If you are using a 2.9 release binary and running a sync domain on protocol version 5, you have the option to upgrade the Canton binary to 2.10 without changing the protocol version from 5 to 7. Remaining on protocol version 5 makes sense if you do not want to use the Smart Contract Upgrade (SCU) feature, for example. In this case, follow the steps for [upgrading the Canton binary](#) instead.

General recipe steps:

1. Start a new sync domain running protocol version 7
2. [Halt activity on the old sync domain](#)
3. Wait for pending transactions to complete or time out
4. Backup the current sync domain including participants
5. Participants: Upgrade the binary to 2.10
6. Participants: [Enable repair commands](#)
7. All nodes: [Test the configuration](#) considering this [additional change](#) if your old domain runs protocol version 3.

8. All nodes: [Apply the DB migrations](#)
9. Participants: Connect to the new sync domain, then disconnect from all domains
10. Participants: Invoke [command](#) `repair.migrate_domain`
11. Participants: Reconnect to the new sync domain
12. Decommission the old domain

Halt activity on the current sync domain

For a sync domain running protocol version 4 and above, set the [dynamic domain parameter](#) `maxRatePerParticipant` to 0 on each participant.

Otherwise, use

```
participant.resources.set_resource_limits(ResourceLimits(Some(0), Some(0)))
```

to set the resource limits to 0 on each participant.

Test the configuration - Additional change if you were running protocol version 3

When migrating from protocol version 3, which uses an unauthenticated contract id scheme, you may need to specifically allow it on the participants.

```
canton.participants.<nodeName>.parameters.allow-for-unauthenticated-contract-  
↪ids=true
```

Please adjust `<nodeName>` to match your case.

IMPORTANT: Please note that you **MUST** set the flag on **ALL** the participants connected to the domain. Failure to do so causes critical failure of the participants.

32.3 Security & Key Management

32.3.1 Cryptographic Key Usage

This section covers the generation and usage of cryptographic keys in the Canton nodes. It assumes that the configuration sets `auto-init = true` which leads to the generation of the default keys on a node's startup.

The scope of cryptographic keys covers all Canton-protocol-specific keys, private keys for TLS, as well as additional keys required for the sync domain integrations, e.g., with Besu.

32.3.1.1 Supported Cryptographic Schemes in Canton

Within Canton we use the cryptographic primitives of signing, symmetric and asymmetric encryption, and MAC with the following supported schemes:

Table 1: **Supported Cryptographic Schemes** - (D = default, S = supported, P = partially supported, for instance just signature verification but no signing with a private key, and / = not supported. Inside the brackets [**<scheme>**] are the values to use when configuring Canton)

Crypto Provider	Tink	JCE	KMS
Signing			
Ed25519 [<i>ed-25519</i>]	D	D	P
ECDSA P-256 [<i>ec-dsa-p-256</i>]	S	S	D
ECDSA P-384 [<i>ec-dsa-p-384</i>]	S	S	S
Symmetric Encryption			
AES128-GCM [<i>aes-128-gcm</i>]	D	D	D
Asymmetric Encryption			
ECIES on P-256 with HMAC-SHA256 and AES128-GCM [<i>ecies-p-256-hkdf-hmac-sha-256-aes-128-gcm</i>]	D	D	P
ECIES on P-256 with HMAC-SHA256 and AES128-CBC [<i>ecies-p-256-hkdf-hmac-sha-256-aes-128-cbc</i>]	/	S	P
RSA 2048 with OAEP and SHA-256 [<i>rsa-2048-oaep-sha-256</i>]	/	S	D
MAC			
HMAC with SHA-256 [<i>hmac-sha-256</i>]	D	D	D

32.3.1.2 Key Generation and Storage

Canton keys are generated in the node and stored in the node's primary storage by default. This does not guarantee that the private keys are protected at rest or at runtime, for instance against a malicious administrator. To counter these threats, Canton allows for the use of a Key Management Service (KMS) to either: (a) *encrypt the stored private keys and protect them at rest* or (b) *directly use the KMS to store and manage the private keys to protect the keys at rest and runtime*. You can find more information on how to configure this service in [Key Management Service \(KMS\) Setup](#).

32.3.1.3 Public Key Distribution using Topology Management

The public keys of the corresponding key pairs that are used for signing and asymmetric encryption within Canton are distributed using Canton's Topology Management. Specifically, signing and asymmetric encryption public keys are distributed using *OwnerToKeyMapping* transactions, which associate a node with a public key for either signing or encryption, and *NamespaceDelegation* for namespace signing public keys.

See [Topology Transactions](#) for details on the specific topology transactions in use.

32.3.1.4 Common Node Keys

Each node provides an Admin API for administrative purposes, which is secured using TLS.

The node reads the private key for the TLS server certificate from a file at startup.

32.3.1.5 Participant Node Keys

Participant Namespace Signing Key

A Canton participant node spans its own identity namespace, for instance for its own id and the Daml parties allocated on the participant node. The namespace is the hash of the public key of the participant namespace signing key.

The private key is used to sign and thereby authorize all topology transactions for this namespace and this participant, including the following transactions:

- Root NamespaceDelegation* for the new identity namespace of the participant
- OwnerToKeyMapping* for all the public keys that the participant will generate and use (these keys will be explained in the follow-up sections)
- PartyToParticipant* for the parties allocated on this participant
- VettedPackages* for the packages that have been vetted by this participant

Signing Key

In addition to the topology signing key, a participant node will generate another signing key pair that is used for the Canton transaction protocol in the following cases:

Sequencer Authentication: Signing the nonce generated by the sequencer as part of its challenge-response authentication protocol. The sequencer verifies the signature with the public key registered for the member in the topology state.

Transaction Protocol

- The Merkle tree root hash of confirmation requests is signed for a top-level view.
- The confirmation responses sent to the mediator are signed as a whole.
- The Merkle tree root hash of transfer-in and transfer-out messages is signed.

Pruning: Signing of ACS commitments.

Participant Encryption Key

In addition to a signing key pair, a participant node also generates a key pair for encryption based on an asymmetric encryption scheme. A transaction payload is encrypted for a recipient based on the recipient's public encryption key that is part of the topology state.

See the next section on how a transaction is encrypted using an ephemeral symmetric key.

View Encryption Key

A transaction is composed of multiple views due to sub-transaction privacy. Instead of duplicating each view by directly encrypting the view for each recipient using their participant encryption public key, Canton derives a symmetric key for each view to encrypt that view. The key is derived using a HKDF from a secure seed that is only stored encrypted under a session key. Thereby, only the encrypted session key is duplicated but not a view.

Session Encryption Key

To avoid having to asymmetrically decrypt the view encryption key for all transactions we make use of a short-lived session key that acts as an intermediary encryption layer positioned between the view encryption and the encryption with the participants' keys. The process involves encrypting and decrypting the session key (that is used to encrypt the view encryption key) using the participants' public and private keys, with the resulting data cached temporarily in memory. This caching mechanism enables similar transactions involving the same participants to make use of the cached information, thereby acquiring the session key without necessitating asymmetric key operations for each transaction.

warning Using session keys can improve overall performance, but increases the impact of a key compromise. With session keys enabled and a session key compromised an attacker could decrypt all (subsequent) views for an informee group until that session key is rotated. Without session keys and a compromised view seed an attacker could only decrypt that view (including subviews). It is possible to either disable caching or adjust the session key rotation time using the Canton configuration file.

```
canton.participants.participant1 {
  caching {
    session-key-cache-config {
      # these are the default values
      enabled = true
      sender-cache {
        maximum-size = 10000
        expire-after-timeout = 10s
      }
      receiver-cache {
        maximum-size = 10000
        expire-after-timeout = 10s
      }
    }
  }
}

# this is how to disable session key caching, by default it's enabled
canton.participants.participant3 {
  caching {
    session-key-cache-config {
      enabled = false
      sender-cache {
        maximum-size = 10000
        expire-after-timeout = 10s
      }
      receiver-cache {
        maximum-size = 10000
      }
    }
  }
}
```

(continues on next page)

(continued from previous page)

```
        expire-after-timeout = 10s
    }
}
}
```

Ledger API TLS Key

The private key for the TLS server certificate is provided as a file, which can optionally be encrypted and the symmetric decryption key is fetched from a given URL.

32.3.1.6 Synchronization Domain Topology Manager Keys

Synchronization Domain Namespace Signing Key

The sync domain topology manager governs the namespace of the sync domain and has a signing key pair for the namespace. The hash of the public key forms the namespace and all entities in the sync domain (mediator, sequencer, the topology manager itself) may have identities under the sync domain namespace.

The sync domain topology manager signs and thereby authorizes the following topology transactions:

- NamespaceDelegation* to register the namespace public key for the new namespace
- OwnerToKeyMapping* to register both its own signing public key (see next section) and the signing public keys of the other sync domain entities as part of the sync domain onboarding
- ParticipantState* to enable a new participant on the sync domain
- MediatorDomainState* to enable a new mediator on the sync domain

Signing Key

The sync domain topology manager is not part of the Canton transaction protocol, but it receives topology transactions via the sequencer. Therefore, in addition to the sync domain namespace, the sync domain topology manager has a signing key pair, which is registered in the topology state for the topology manager. This signing key is used to perform the challenge-response protocol of the sequencer.

32.3.1.7 Sequencer Node Keys

Signing Key

The sequencer has a signing key pair that is used to sign all events the sequencer sends to a subscriber.

Ethereum Sequencer

The Ethereum-based sequencer is a client of a Besu node and additional keys are used in this deployment:

- TLS client certificate and private key to authenticate towards a Besu node if mutual authentication is configured.

- A Wallet (in BIP-39 or UTC / JSON format), which contains or will result in a signing key pair for Ethereum transactions.

Fabric Sequencer

The Fabric-based sequencer is a Fabric application connecting to an organization's peer node and the following additional keys are required:

- TLS client certificate and private key to authenticate towards a Fabric peer node if mutual authentication is required.

- The client identity's certificate and private key.

Public API TLS Key

The private key for the TLS server certificate is provided as a file.

32.3.1.8 Mediator Node Keys

Signing Key

The mediator node is part of the Canton transaction protocol and uses a signing key pair for the following:

- Sequencer Authentication: Signing of the challenge as part of the sequencer challenge-response protocol.

- Signing of transaction results, transfer results, and rejections of malformed mediator requests.

32.3.1.9 Synchronizer Domain Node Keys

The sync domain node embeds a sequencer, mediator, and sync domain topology manager. The set of keys remains the same as for the individual nodes.

32.3.1.10 Canton Console Keys

When the Canton console runs separately from the node and mutual authentication is configured on the Admin API, then the console requires a TLS client certificate and the corresponding private key as a file.

32.3.2 Cryptographic Key Management

32.3.2.1 Rotating Canton Node Keys

Canton supports the rotation of node keys (signing and encryption) during live operation through its topology management. In order to ensure continuous operation, the new key is added first and then the previous key is removed.

For participant nodes, sync domain nodes, and sync domain topology managers, the nodes can rotate their keys directly using their own identity manager with the following command for example:

```
participant1.keys.secret.rotate_node_keys()
```

On a participant node both the signing and encryption key pairs are rotated. On a sync domain and sync domain manager node only the signing key pair, because they do not have an encryption key pair. Identity namespace root or intermediate keys are not rotated with this command, see below for commands on namespace key management.

For sequencer and mediator nodes that are part of a sync domain, the sync domain topology manager authorizes the key rotation and a reference needs to be passed in to the command, for example:

```
domainManager1.keys.secret.rotate_node_keys()  
sequencer1.keys.secret.rotate_node_keys(domainManager1)  
mediator1.keys.secret.rotate_node_keys(domainManager1)
```

We can also individually rotate a key by running the following command for example:

```
participant1.keys.secret.rotate_node_keys()
```

A fingerprint of a key can be retrieved from the list of public keys:

```
participant2.keys.secret  
  .list()
```

32.3.2.2 Deleting Canton Node Keys

Keys, particularly private keys, are not deleted automatically in Canton. When a key is rotated, the previous key is still stored but no longer enabled or used. To permanently delete a key, use the following Canton console command:

```
domainManager1.keys.secret.delete(privateKeyId, force = true)
```

Warning: Exercise caution when deleting a private key. You must ensure that the key is no longer in use and is not needed for decrypting or creating signatures for old messages. Therefore, you

should only delete a key when the node has been pruned for a timestamp later than the point in time when the key was deactivated. This is especially crucial for sequencers in open networks. For example, if a participant lags in retrieving sequenced events, and the sequencer's signing key is rolled, the old signing key must remain accessible to sign the events from before the key roll for lagging participants. Otherwise, deleting the key prematurely may cause irreversible issues for these participants.

32.3.2.3 Namespace Intermediate Key Management

Relying on the namespace root key to authorize topology transactions for the namespace is problematic because we cannot rotate the root key without losing the namespace. Instead we can create intermediate keys for the namespace, similar to an intermediate certificate authority, in the following way:

```
// create a new namespace intermediate key
val intermediateKey = identityManager.keys.secret.generate_signing_key()

// Create a namespace delegation for the intermediate key with the namespace root
↳key
identityManager.topology.namespace_delegations.authorize(
    TopologyChangeOp.Add,
    rootKey.fingerprint,
    intermediateKey.fingerprint,
)
```

We can rotate an intermediate key by creating a new one and renewing the existing topology transactions that have been authorized with the previous intermediate key. First the new intermediate key has to be created in the same way as the initial intermediate key. To rotate the intermediate key and renew existing topology transactions:

```
// Renew all active topology transactions that have been authorized by the
↳previous intermediate key with the new intermediate key
identityManager.topology.all.renew(intermediateKey.fingerprint,
↳newIntermediateKey.fingerprint)

// Remove the previous intermediate key
identityManager.topology.namespace_delegations.authorize(
    TopologyChangeOp.Remove,
    rootKey.fingerprint,
    intermediateKey.fingerprint,
)
```

32.3.2.4 Moving the Namespace Secret Key to Offline Storage

An identity is ultimately bound to a particular secret key. Owning that secret key gives full authority over the entire namespace. From a security standpoint, it is therefore critical to keep the namespace secret key confidential. This can be achieved by moving the key off the node for offline storage. The identity management system can still be used by creating a new key and an appropriate intermediate certificate. The following steps illustrate how:

```
// fingerprint of namespace giving key
val participantId = participant1.id
val namespace = participantId.uid.namespace.fingerprint

// create new key
val name = "new-identity-key"
val fingerprint = participant1.keys.secret.generate_signing_key(name = name).
↳fingerprint

// create an intermediate certificate authority through a namespace delegation
// we do this by adding a new namespace delegation for the newly generated key
// and we sign this using the root namespace key
participant1.topology.namespace_delegations.authorize(
  TopologyChangeOp.Add,
  namespace,
  fingerprint,
  signedBy = Some(namespace),
)

// export namespace key to file for offline storage, in this example, it's a
↳temporary file
better.files.File.usingTemporaryFile("namespace", ".key") { privateKeyFile =>
  participant1.keys.secret.download_to(namespace, privateKeyFile.toString)

  // delete namespace key (very dangerous ...)
  participant1.keys.secret.delete(namespace, force = true)
```

When the root namespace key is required, it can be imported again on the original node or on another, using the following steps:

```
// import it back wherever needed
other.keys.secret.upload(privateKeyFile.toString, Some("newly-imported-identity-
↳key"))
```

32.3.2.5 Identifier Delegation Key Management

Identifier delegations work similar to namespace delegations, however a key is only allowed to operate on a specific identity and not an entire namespace (cf. [Topology Transactions](#)).

Therefore the key management for identifier delegations also works the same way as for namespace delegations, where all the topology transactions authorized by the previous identifier delegation key have to be renewed.

32.3.3 Ledger-API Authorization

The Ledger API provides [authorization support](#) using [JWT](#) tokens. While the JWT token authorization allows third-party applications to be authorized properly, it poses some issues for Canton internal services such as the *PingService* or the *DarService*, which are used to manage sync domain-wide concerns. Therefore Canton generates a new admin bearer token (64 bytes, randomly generated, hex-encoded) on each startup, which is communicated to these services internally and used by these services to authorize themselves on the Ledger API. The admin token allows to act as any party registered on that participant node.

The admin token is only used within the same process. Therefore, in order to obtain this token, an attacker needs to be able to either dump the memory or capture the network traffic, which typically only a privileged user can do.

It is important to enable TLS together with JWT support in general, as otherwise tokens can be leaked to an attacker that has the ability to inspect network traffic.

32.4 Key Management Service (KMS) Setup

Important: [Daml Enterprise license](#) required

By default Canton keys are generated in the node and stored in the node's primary storage. We currently support a version of Canton that can use a KMS to either: (a) [protect Canton's private keys at rest](#) or (b) [generate and store the private keys itself](#).

You can find more background information on this key management feature in [Secure Cryptographic Private Key Storage](#). See [Protect Private Keys With Envelope Encryption and a Key Management Service](#) if you want to know how Canton can protect private keys while they remain internally stored in Canton using a KMS, or [Externalize Private Keys With a Key Management Service](#) for more details on how Canton can enable private keys to be generated and stored by an external KMS.

The following sections describe how to enable KMS support in Canton and how to setup each mode of operation.

32.4.1 Canton Configuration of a KMS

Important: [Daml Enterprise license](#) required

Canton supports using a Key Management Service (KMS) to increase security of stored private keys. Note that for Canton to actually use a KMS you also need to decide and configure one of the **two independent ways** to use this service:

- [Encrypted Private Key Storage](#)
- [External Key Storage](#)

The KMS configuration is currently enabled for Amazon Web Services (AWS) KMS and Google Cloud Provider (GCP) KMS in Canton Enterprise.

32.4.1.1 Configure Amazon Web Services (AWS) KMS

Like other Canton capabilities, AWS KMS configuration is enabled within a Canton node's configuration file. A KMS for AWS is configured as follows:

```
canton.participants.participant1.crypto.kms {  
  type = aws  
  region = us-east-1  
  multi-region-key = false # optional, default is false  
  audit-logging = false # optional, default is false  
}
```

`type` specifies which KMS to use.

`region` specifies which region the AWS KMS is bound to.

`multi-region-key` flag enables the replication of keys generated by the AWS KMS. With replication turned on, the operator can replicate a key from one region to another (Note: replication of a key is not done automatically by Canton) and change the region configured in Canton at a later point in time without any other key rotation required. **The standard single-region approach is applicable for most scenarios.**

`audit-logging` flag enables logging of every call made to the AWS KMS.

Configure AWS Credentials and Permissions

The authorized actions (i.e. IAM permissions) for the AWS KMS depend on the mode of operation you are running, either: (a) [an encrypted private key storage using envelope encryption](#); or (b) [externally storing and using keys directly from AWS KMS](#). A complete list is given in those sections.

To make the API calls to the AWS KMS, Canton uses the [standard AWS credential access](#). For example, the standard environment variables of `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` can be used. Alternatively, you can specify an AWS profile file (e.g. use a temporary access profile credentials - sts).

The protection and rotation of the credentials for AWS are the responsibility of the node operator.

Auditability

AWS provides tools to monitor KMS keys. For AWS to set automatic external logging, refer to the [AWS official documentation](#). This includes instructions on how to set AWS Cloud Trail or Cloud Watch Alarms to keep track of usage of KMS keys or of performed crypto operations. Canton logs errors resulting from the use of KMS keys.

Logging

For further auditability, Canton can be configured to log every call made to the AWS KMS. To enable this feature, set the `audit-logging` field of the KMS configuration to `true`. By default, when using a file-based logging configuration, such logs are written into the main Canton log file. To write them to a dedicated log file, set the `KMS_LOG_FILE_NAME` environment variable or `--kms-log-file-name` CLI flag to the path of the file. These and other parameters can be configured using environment variables or CLI flags:

Table 2: KMS logging configuration

Environment variable	CLI Flag	Purpose	Default
KMS_LOG_FILE_NAME	<code>--kms-log-file-name</code>	Path to a dedicated KMS log file	not set
KMS_LOG_IMMEDIATE_FLUSH	<code>-kms-log-immediate-flush</code>	If <code>true</code> , logs will be immediately flushed to the KMS log file	<code>true</code>
KMS_LOG_FILE_ROLLING_PATTERN	<code>--kms-log-file-rolling-pattern</code>	Pattern to use when using the rolling file strategy to roll KMS log files	<code>yyyy-MM-dd</code>
KMS_LOG_FILE_HISTORY	<code>--kms-log-file-history</code>	Maximum number of KMS log files to keep when using the rolling file strategy	0 (i.e. no limit)

Sample of an AWS KMS audit log:

```

2023-09-12 15:44:54,426 [env-execution-context-27] INFO c.d.c.c.k.a.a.

```

Note that sensitive data is removed before logging. The general log format is as follows:

```

tid:<canton_trace_id> - Sending request [<canton_kms_request_id>]:
<request details>                                tid:<canton_trace_id> - Received response
[<canton_kms_request_id>]: [Aws-Id: <aws_request_id>] - <response details>

```

32.4.1.2 Configure Google Cloud Provider (GCP) KMS

Like other Canton capabilities, GCP KMS configuration is enabled within a Canton node's configuration file. A KMS for GCP is configured in the following way:

```
canton.participants.participant2.crypto.kms {  
  type = gcp  
  location-id = us-east1  
  project-id = gcp-kms-testing  
  key-ring-id = canton-test-keys-2023  
  audit-logging = false # optional, default is false  
}
```

`type` specifies which KMS to use.

`location-id` specifies which region the GCP KMS is bound to.

`project-id` specifies which project are we binding to.

`key-ring-id` specifies the keyring to use. Multi region keys are enabled for an entire keyring. Therefore, the KMS operator is responsible for setting the keyring correctly depending on the systems' needs.

`audit-logging` flag that enables logging of every call made to the GCP KMS

Configure GCP Credentials and Permissions

The authorized actions (i.e. IAM permissions) for the GCP KMS depend on the mode of operation we are running, either: (a) [an encrypted private key storage using envelope encryption](#); or (b) [externally storing and using keys directly from GCP KMS](#). A complete list is given in those sections.

For GCP, Canton uses a [GCP service account](#). For example, the standard environment variable `GOOGLE_APPLICATION_CREDENTIALS` can be used after setting up a local Application Default Credentials (ADC) file for the service account. For supported environments, e.g. GKE, Canton can pick up credentials from the metadata service [Application Default Credentials](#).

The protection and rotation of the credentials for GCP are the responsibility of the node operator.

Auditability

GCP provides tools to monitor KMS keys. For GCP logging information you can refer to the [GCP official documentation](#). Canton logs errors resulting from the use of KMS keys.

Logging

For further auditability, Canton can be configured to log every call made to the GCP KMS. To enable this feature, set the `audit-logging` field of the KMS configuration to `true`. By default, when using a file-based logging configuration, such logs are written into the main Canton log file. To write them to a dedicated log file, set the `KMS_LOG_FILE_NAME` environment variable or `--kms-log-file-name` CLI flag to the path of the file. These and other parameters can be configured using environment variables or CLI flags:

Table 3: KMS logging configuration

Environment variable	CLI Flag	Purpose	Default
KMS_LOG_FILE_NAME	<code>--kms-log-file-name</code>	Path to a dedicated KMS log file	not set
KMS_LOG_IMMEDIATE_FLUSH	<code>-kms-log-immediate-flush</code>	If <code>true</code> , logs will be immediately flushed to the KMS log file	<code>true</code>
KMS_LOG_FILE_ROLLING_PATTERN	<code>--kms-log-file-rolling-pattern</code>	Pattern to use when using the rolling file strategy to roll KMS log files	<code>yyyy-MM-dd</code>
KMS_LOG_FILE_HISTORY	<code>--kms-log-file-history</code>	Maximum number of KMS log files to keep when using the rolling file strategy	0 (i.e. no limit)

Sample of a GCP KMS audit log:

```

2023-09-12 15:44:54,426 [env-execution-context-27] INFO c.d.c.c.k.g.a.

32.4.2 Configure Encrypted Private Key Storage with a Key Management Service (KMS)

Important: [Daml Enterprise license](#) required

Canton can use a KMS to protect Canton's private keys at rest:

1. Store Canton's private keys in a node's database in an encrypted form
2. Upon startup, the KMS decrypts these keys for use by Canton.

The unencrypted keys are stored in memory so this approach increases security without impacting performance. This is a common approach used by KMS vendors; using a symmetric encryption key, called the *wrapper key*, to encrypt and decrypt the stored, private keys.

See [Protect Private Keys With Envelope Encryption and a Key Management Service](#) for more details.

Currently Canton supports encrypted private key storage with [Amazon Web Services \(AWS\) KMS](#) or [Google Cloud Provider \(GCP\) KMS](#).

32.4.2.1 Configure Encrypted Private Key Storage with AWS KMS

Important: [Daml Enterprise license](#) required

The following section describes the steps needed to enable [Encrypted Private Key Storage](#) in Canton using AWS KMS. These steps include configuring AWS KMS, as well as configuring this particular mode of operation.

AWS KMS Configuration

To start using this feature you must first enable AWS KMS for Canton:

[-Configure AWS KMS for Canton-](#)

The following IAM permissions are required:

```
kms:CreateKey
kms:Encrypt
kms:Decrypt
kms:DescribeKey
```

When you are using cross-account keys, you do not need the `kms:CreateKey` permission.

Encrypted Private Key Storage Configuration

Both new and existing nodes can be configured to use this feature. **In both cases, keys are stored encrypted in the Canton node's database**

The example below configures encrypted private key storage with AWS KMS, for all nodes, in a simple distributed sync domain environment.

```
canton.domain-managers.domainManager1.crypto = ${_shared_aws.crypto}
canton.sequencers.sequencer1.crypto = ${_shared_aws.crypto}
canton.mediators.mediator1.crypto = ${_shared_aws.crypto}
canton.participants.participant1.crypto = ${_shared_aws.crypto}
```

```
_shared_aws {
  # Configure an AWS KMS
  crypto {
    kms {
      type = aws
      region = us-east-1
    }
  }
}
```

(continues on next page)

(continued from previous page)

```

    multi-region-key = false
    audit-logging = false
  }

  # Configure an encrypted store with KMS
  private-key-store {
    encryption.type = kms
    # In this example we are using the same wrapper key for all nodes. This is
    ↪not recommended and you should
    # either let Canton generate those keys or choose a different one for each
    ↪node.
    encryption.wrapper-key-id = alias/canton-kms-test-key
  }
}

```

As seen before, `crypto.kms` [configures AWS KMS](#). Subsequently, `crypto.private-key-store.encryption.type = kms` enables encrypted private key storage using a KMS.

Finally `crypto.private-key-store.encryption.wrapper-key-id` is an **optional field** to specify an existing (default) KMS key to use as the encryption key. If this field is left empty, Canton creates a new key.

Supported values are:

Key id: `1234abcd-12ab-34cd-56ef-1234567890ab`

Key ARN (Amazon Resource Name): `arn:aws:kms:us-east-1:1234abcd-12ab-34cd-56ef-1234567890ab`

Key alias: `alias/test-key`

Note that if you are using an existing AWS key, it should be created as follows:

Key specification: [SYMMETRIC_DEFAULT](#)

Key usage: [ENCRYPT_DECRYPT](#)

After subsequent restarts the operator does not need to specify the identifier for the wrapper key; Canton stores the generated wrapper key ID in the database.

Important: Restoring from a database backup requires access to the wrapper keys used during the encryption of the data in the backup. Deleting the wrapper keys renders the backup unusable.

Revert Encrypted Private Key Storage

Encrypted Private Key Storage can be reverted back to unencrypted storage. To prevent accidental reverts, simply deleting the `private-key-store` configuration does **not** revert to unencrypted storage. Instead, the following configuration must be added:

```

canton.participants.participant1.crypto.private-key-store.encryption.reverted =
↪true # default is false

```

Warning: This forces Canton to decrypt its private keys and store them in clear; it is not recommended.

Encrypted private key storage can be enabled again by deleting the `reverted` field and reconfiguring it as shown in [Encrypted Private Key Storage Configuration](#).

Manual Wrapper Key Rotation

AWS offers automatic KMS symmetric key rotation (yearly). Canton extends this by enabling node administrators to manually rotate the KMS wrapper key using the following command:

```
participant1.keys.secret.rotate_wrapper_key(newWrapperKeyId)
```

You can pass a wrapper key ID to change to or let Canton generate a new key based on the current AWS KMS configuration.

Note: Changing the key specification (e.g. enable multi region) during rotation can be done by updating the configuration before rotating the wrapper key.

Key rotation does not delete the previous key. Although the key can no longer be used, it persists. To permanently delete the previous key, refer to [Deleting Canton Node Keys](#).

Interoperability

Nodes configured with and without encrypted private key storage can interact with each other, including nodes using different KMS providers.

32.4.2.2 Configure Encrypted Private Key Storage with GCP KMS

Important: [Daml Enterprise license](#) required

The following section describes the steps needed to enable [Encrypted Private Key Storage](#) in Canton using GCP KMS. These steps include configuring GCP KMS, as well as configuring this particular mode of operation.

GCP KMS Configuration

To start using this feature you must first enable GCP KMS for Canton:

[-Configure GCP KMS for Canton-](#)

The following IAM permissions are required:

```
cloudkms.cryptoKeyVersions.create
cloudkms.cryptoKeyVersions.useToEncrypt
cloudkms.cryptoKeyVersions.useToDecrypt
cloudkms.cryptoKeys.get
```

When you are using cross-account keys, you do not need the `cloudkms.cryptoKeyVersions.create` permission.

Encrypted Private Key Storage Configuration

Both new and existing nodes can be configured to use this feature. **In both cases, keys are stored encrypted in the Canton node's database**

The example below configures encrypted private key storage with GCP KMS, for all nodes, in a simple distributed sync domain environment.

```
canton.domain-managers.domainManager1.crypto = ${_shared_gcp.crypto}
canton.sequencers.sequencer1.crypto = ${_shared_gcp.crypto}
canton.mediators.mediator1.crypto = ${_shared_gcp.crypto}
canton.participants.participant1.crypto = ${_shared_gcp.crypto}
```

```
_shared_gcp {
  # Configure an GCP KMS
  crypto {
    kms {
      type = gcp
      location-id = us-east1
      project-id = gcp-kms-testing
      key-ring-id = canton-test-keys-2023
      audit-logging = false # optional, default is false
    }

    # Configure an encrypted store with KMS
    private-key-store {
      encryption.type = kms
      # In this example we are using the same wrapper key for all nodes. This is
      ↪not recommended and you should
      ↪either let Canton generate those keys or choose a different one for each
      ↪node.
      encryption.wrapper-key-id = canton-kms-test-key
    }
  }
}
```

As seen before, `crypto.kms` [configures GCP KMS](#). Subsequently, `crypto.private-key-store.encryption.type = kms` enables encrypted private key storage using a KMS.

Finally `crypto.private-key-store.encryption.wrapper-key-id` is an **optional field** to specify an existing (default) KMS key to use as the encryption key. If this field is left empty, Canton creates a new key.

Supported values are:

Key name: `test-key`

Key RN (Resource Name): `projects/gcp-kms-testing/locations/us-east1/keyRings/canton-test-keys/cryptoKeys/t`

Note that if you are using an existing GCP key, it should be created as follows:

Key algorithm: [GOOGLE_SYMMETRIC_ENCRYPTION](#)

Key purpose: `ENCRYPT_DECRYPT`

After subsequent restarts the operator does not need to specify the identifier for the wrapper key; Canton stores the generated wrapper key ID in the database.

Important: Restoring from a database backup requires access to the wrapper keys used during the

encryption of the data in the backup. Deleting the wrapper keys renders the backup unusable.

Revert Encrypted Private Key Storage

Encrypted Private Key Storage can be reverted back to unencrypted storage. To prevent accidental reverts, simply deleting the `private-key-store` configuration does **not** revert to unencrypted storage. Instead, the following configuration must be added:

```
canton.participants.participant1.crypto.private-key-store.encryption.reverted =  
→ true # default is false
```

Warning: This forces Canton to decrypt its private keys and store them in clear; it is not recommended.

Encrypted private key storage can be enabled again by deleting the `reverted` field and reconfiguring it as shown in [Encrypted Private Key Storage Configuration](#).

Manual Wrapper Key Rotation

GCP offers automatic KMS symmetric key rotation (user-defined time). Canton extends this by enabling node administrators to manually rotate the KMS wrapper key using the following command:

```
participant1.keys.secret.rotate_wrapper_key(newWrapperKeyId)
```

You can pass a wrapper key ID to change to or let Canton generate a new key based on the current GCP KMS configuration.

Warning: It is not currently possible to change the key specification (e.g. enable multi-region) during rotation.

Key rotation does not delete the previous key. Although the key can no longer be used, it persists. To permanently delete the previous key, refer to [Deleting Canton Node Keys](#).

Interoperability

Nodes configured with and without encrypted private key storage can interact with each other, including nodes using different KMS providers.

32.4.3 Configure External Key Storage with a Key Management Service (KMS)

Important: [Daml Enterprise license](#) required

Canton can delegate all asymmetric decryption and signing operations to a KMS. In that mode, private keys are stored in the KMS, not in Canton's own storage nor in memory. Decryption and signing operations each require an API call to the KMS. A Canton node still stores the corresponding public keys in its stores so that it can verify signatures and encrypt messages without having to rely on the KMS.

See [Externalize Private Keys With a Key Management Service](#) for more details.

Currently Canton supports external key storage with [Amazon Web Services \(AWS\) KMS](#) or [Google Cloud Provider \(GCP\) KMS](#).

32.4.3.1 Configure External Key Storage with AWS KMS

Important: [Daml Enterprise license](#) required

The following section describes the steps needed to enable [External Key Storage](#) in Canton using AWS KMS. These steps include configuring AWS KMS, as well as configuring this particular mode of operation.

AWS KMS Configuration

To start using this feature you must first enable a KMS for Canton.

–Configure AWS KMS for Canton–

The following IAM permissions are required:

- `kms:CreateKey`
- `kms:TagResource`
- `kms:Decrypt`
- `kms:Sign`
- `kms:DescribeKey`
- `kms:GetPublicKey`

When you are using cross-account keys, you do not need the `kms:CreateKey` and `kms:TagResource` permissions.

External Key Storage Configuration

External key storage support can be enabled for a new installation (i.e., during the node bootstrap) or for an existing deployment. **Be aware that if a node has already been deployed you need to [perform a node migration](#).** Simply adding the following configuration is not enough.

In the example below, we configure a **new** Canton participant node (called `participant1`) to generate and store private keys in an external AWS KMS. The same configuration is applicable for all other node entities, including the sync domain manager, mediators, and sequencers.

```
canton.participants.participant1.crypto.provider = kms
```

An example configuration that puts together both AWS KMS and external storage configuration is shown below:

```
canton.participants.participant1.crypto.provider = kms
canton.participants.participant1.crypto.kms {
  type = aws
  region = us-east-1
  multi-region-key = false # optional, default is false
  audit-logging = true # optional, default is false
}
```

Setup with Pre-Generated Keys

In the previous example, Canton creates its own keys on startup and initializes the identity of the nodes automatically. To use pre-generated keys, you need to manually initialize the identity of the nodes by adding the following to each node's configuration:

```
<node>.init.auto-init = false
```

This is only applicable for `participant` and `domain/domain-manager` nodes.

Afterwards, we need to register the keys in Canton by running the key registration command on each node. For example for a `participant` you would run:

```
participant.keys.secret
  .register_kms_signing_key(namespaceKmsKeyId, name = participant.name + "-
↪namespace") ->
  participant.keys.secret
  .register_kms_signing_key(signingKmsKeyId, name = participant.name + "-signing
↪") ->
  participant.keys.secret
  .register_kms_encryption_key(encryptionKmsKeyId, name = participant.name + "-
↪encryption")
```

where `xyzKmsKeyId` is the AWS KMS identifier for a specific key (e.g. KMS Key ARN). When using [AWS cross account keys](#) the key ID can't be used, use the key ARN instead.

Here is a reminder of the initial keys that each node owns:

Table 4: List of keys that each node owns

Keys	Sync Domain	Sequencer	Mediator	Participant
(Signing) Namespace Key	x	x		x
Signing Key	x	x	x	x
(Asymmetric) Encryption Key				x

Depending on the key purpose and the default signing and encryption schemes defined in Canton, you need to pre-generate the corresponding AWS KMS keys with the correct settings:

Table 5: AWS key configuration

Provider	SIGNING	ENCRYPTION
AWS	Key Purpose: SIGN_VERIFY Key Algorithms: ECC_NIST_P256 or ECC_NIST_P384	Key Purpose: ENCRYPT_DECRYPT Key Algorithm: RSA_2048

Below are links to guides on how to manually initialize participant and sync domain nodes in different settings. In those guides, keys are generated using console commands such as:

```
val identityKey = participant.keys.secret.generate_signing_key(name = participant.  
  ↪name + "-namespace")
```

Make sure to **replace those commands with the ones shown above** with which you registered your existing keys instead of generating new ones.

[initialize sync domain](#)
[initialize participants](#)

32.4.3.2 Configure External Key Storage with GCP KMS

Important: [Daml Enterprise license](#) required

The following section describes the steps needed to enable [External Key Storage](#) in Canton using GCP KMS. These steps include configuring GCP KMS, as well as configuring this particular mode of operation.

GCP KMS Configuration

To start using this feature you must first enable a KMS for Canton.

[-Configure GCP KMS for Canton-](#)

The following IAM permissions are required:

```
cloudkms.cryptoKeyVersions.create
cloudkms.cryptoKeyVersions.useToDecrypt
cloudkms.cryptoKeyVersions.useToSign
cloudkms.cryptoKeyVersions.get
cloudkms.cryptoKeyVersions.viewPublicKey
```

When you are using cross-account keys, you do not need the `cloudkms.cryptoKeyVersions.create` permission.

External Key Storage Configuration

External key storage support can be enabled for a new installation (i.e., during the node bootstrap) or for an existing deployment. **Be aware that if a node has already been deployed you need to [perform a node migration](#).** Simply adding the following configuration is not enough.

In the example below, you configure a Canton participant node (called `participant1`) to generate and store private keys in an external GCP KMS. The same configuration is applicable for all other node entities, including the sync domain manager, mediators, and sequencers.

```
canton.participants.participant1.crypto.provider = kms
```

An example configuration that puts together both KMS and external storage configuration is shown below:

```
canton.participants.participant1.crypto.provider = kms
canton.participants.participant1.crypto.kms {
  type = gcp
  location-id = us-east1
  project-id = gcp-kms-testing
  key-ring-id = canton-test-keys-2023
  audit-logging = true # optional, default is false
}
```

Setup with Pre-Generated Keys

In the previous example, Canton creates its own keys on startup and initializes the identity of the nodes automatically. To use pre-generated keys, you need to manually initialize the identity of the nodes by adding the following to each node's configuration:

```
<node>.init.auto-init = false
```

This is only applicable for participant and domain/domain-manager nodes.

Afterwards, we need to register the keys in Canton by running the key registration command on each node. For example for a participant you would run:

```

participant.keys.secret
  .register_kms_signing_key(namespaceKmsKeyId, name = participant.name + "-
↳namespace") ->
participant.keys.secret
  .register_kms_signing_key(signingKmsKeyId, name = participant.name + "-signing
↳") ->
participant.keys.secret
  .register_kms_encryption_key(encryptionKmsKeyId, name = participant.name + "-
↳encryption")

```

where `xyzKmsKeyId` is the GCP KMS identifier for a specific key (e.g. KMS Key ARN).

Here is a reminder of the initial keys that each node owns:

Table 6: List of keys that each node owns

Keys	Sync Do- main	Sync Domain Manager	Se- quencer	Mediator	Partici- pant
(Signing) Names- pace Key	x	x			x
Signing Key	x	x	x	x	x
(Asymmetric) En- ryption Key					x

Depending on the key purpose and the default signing and encryption schemes defined in Canton, you need to pre-generate the corresponding GCP KMS keys with the correct settings:

Table 7: GCP key configuration

Provider	SIGNING	ENCRYPTION
GCP	Key Purpose: ASYMMET- RIC_SIGN Key Algorithms: EC_SIGN_P256_SHA256 or EC_SIGN_P384_SHA384	Key Purpose: ASYMMET- RIC_DECRYPT Key Algorithm: RSA_DE- CRYPT_OAEP_2048_SHA256

Below are links to guides on how to manually initialize participant and sync domain nodes in different settings. In those guides, keys are generated using console commands such as:

```

val identityKey = participant.keys.secret.generate_signing_key(name = participant.
↳name + "-namespace")

```

Make sure to **replace those commands with the ones shown above** with which you registered your existing keys instead of generating new ones.

[initialize sync domain](#)
[initialize participants](#)

32.4.3.3 Interoperability with other nodes

By default nodes in Canton run a `tink` provider that is not compatible with KMS provider that stores the Canton private keys. If you want to continue to have other nodes running a *non-KMS* Canton you are obliged to use a `jce` provider and you must explicitly configure it to use the KMS supported algorithms as the required algorithms. Here is an example on how to set it up for a simple distributed sync domain:

```
canton.domain-managers.domainManager1 = {
  crypto.provider = jce
  domain-parameters.protocol-version = 7
}

canton.sequencers.sequencer1.crypto = {
  provider = jce
}

canton.mediators.mediator1.crypto = {
  provider = jce
}
```

And here is an example for a participant:

```
canton.participants.participant2.crypto = {
  provider = jce
}
```

In other words, a node running with a `kms` provider (which is externally storing Canton private keys) is only ever able to communicate with other nodes running a `kms` or `jce` providers.

See [this table](#) for a description of cryptographic schemes supported by the KMS provider.

32.4.3.4 Participant Node Migration to KMS

To migrate an existing participant node connected to a sync domain with a non-KMS-compatible provider and start using KMS external keys, you need to follow one of the next guides. The general idea is to replicate the old node into a new one that uses a KMS crypto provider and connects to a KMS-compatible sync domain (e.g. [running JCE with KMS-supported encryption and signing keys](#)).

Two different methods are available for performing this migration: (a) [migrate to a new participant that uses the same namespace identity](#) and (b) [migrate to a new participant with an entire new identity and namespace](#). The first option does not require you to change the party ids for the active contracts in the old participant, and it can be done by a single operator, because it is a transparent process for the other operators and their shared contracts. However, the old domain must support the new protocol version and the original root namespace key must be kept safe to allow the future migration to a new protocol version. The second option re-writes the contracts with new party identifiers in line with the new participant namespace. Therefore, you do not need to preserve the original root namespace key for a future migration. This works even if the old domain node does not support the new protocol version. However, for it to work, a single operator must control all the contracts or all participant operators have to agree on this rewrite.

Participant Node Migration with the Same Namespace

One way of migrating a non-KMS participant to a new KMS-enabled one is to create a new participant connected to a KMS-compatible sync domain (e.g. [running JCE with KMS-supported encryption and signing keys](#)) and then transfer the data from the old node to the new one. In this example, you transfer the parties, contracts, and DARs, along with the node's identity. Thus, both the old and new participants share the same namespace. This has the advantage of being feasible in a multi-operator setting even when the other operators do not agree to this migration, because it is transparent to them and their shared contracts.

Warning: You must save the [root namespace key](#) of the old participant somewhere offline so that it can be used, in the future, to migrate the node to a new protocol version. This is necessary because you need to sign topology transactions with the root namespace key everytime you migrate a node to a new protocol version that is not supported by the old domain.

First, delegate the namespace of the old participant to the new participant:

```
val namespaceOld = participantOld.uid.namespace.fingerprint
val namespaceNew = participantNew.uid.namespace.fingerprint

val rootNamespaceDelegationOld = participantOld.topology.namespace_delegations
    .list(filterNamespace = namespaceOld.toProtoPrimitive)
    .head
    .context
    .serialized

val namespaceKeyNew = participantNew.keys.public.download(namespaceNew)
participantOld.keys.public.upload(namespaceKeyNew, Some("pNew-namespace-key"))

// Delegate namespace of old participant to new participant
val delegation = participantOld.topology.namespace_delegations.authorize(
    ops = TopologyChangeOp.Add,
    namespace = namespaceOld,
    authorizedKey = namespaceNew,
)

participantNew.topology.load_transaction(rootNamespaceDelegationOld)
participantNew.topology.load_transaction(delegation)
```

Secondly, you must recreate all parties of the old participant in the new participant:

```
/* Disconnect the old participant from the old domain to avoid new parties or
↳ contracts being created
 * Make sure domain and the old participant are quiet before exporting the
↳ parties or the ACS
 */
participantOld.domains.disconnect(oldDomainAlias)

// Disconnect from new KMS-compatible domain to prepare migration of parties and
↳ contracts
participantNew.domains.disconnect(newDomainAlias)

// Determine all parties hosted on the old participants, except for admin parties
```

(continues on next page)

(continued from previous page)

```

val parties = participantOld.ledger_api.parties
    .list()
    .filter(party =>
        party.party.toProtoPrimitive != participantOld.uid.toProtoPrimitive && party.
        ↪isLocal
    )
    .map(_.party)

parties.foreach { party =>
    participantNew.topology.party_to_participant_mappings
        .authorize(ops = TopologyChangeOp.Add, party = party, participant = ↪
        ↪participantNew.id)
}

```

Thirdly, you should migrate your DARs to the new participant:

```

// Migrate DARs from old to new participant
utils.migrate_dars(participantOld, participantNew)

```

Finally, you need to transfer the active contracts of all the parties from the old participant to the new one and connect to the new sync domain:

```

val parties = participantOld.ledger_api.parties
    .list()
    .filter(party =>
        party.party.toProtoPrimitive != participantOld.uid.toProtoPrimitive && party.
        ↪isLocal
    )
    .map(_.party)

// There should be no conflicts between the protocol version of the old domain ↪
↪and the new domain
val protocolVersion = newKmsDomainManager.config.init.domainParameters.
    ↪initialProtocolVersion

File.usingTemporaryFile("participantOld-acs", suffix = ".txt") { acsFile =>
    val acsFileName = acsFile.toString

    // Export from old participant
    participantOld.repair.export_acs(
        parties = parties.toSet,
        outputFile = acsFileName,
        contractDomainRenames = Map(oldDomainId -> (newKmsDomainId, protocolVersion)),
        partiesOffboarding = false,
    )

    // Import to new participant
    participantNew.repair.import_acs(acsFileName, parties.toSet)
}

// Kill/stop the old participant
participantOld.stop()

// Connect the new participant to the new domain
participantNew.domains.reconnect(newKmsDomainAlias)

```

The result is a new participant node, that retains the old namespace, with its keys stored and managed by a KMS connected to a sync domain that can communicate using the appropriate key schemes.

You need to follow the same steps if you want to migrate a node back to using a non-KMS provider.

Participant Node Migration with a New Namespace

To migrate a non-KMS participant to a KMS-enabled one you need to make sure you have this new participant connected to a KMS-compatible sync domain (e.g. [running JCE with KMS-supported encryption and signing keys](#)). Afterwards, you transfer all parties, active contracts and DARs from the old participant to the new one. Since, in this case, you do not transfer the identities from the old node to the new one. You need to re-write your contracts to refer to the new party ids. With this method, you can easily migrate your old participant that runs an older protocol version to a new participant with KMS enabled that can be running a more recent protocol version. Furthermore, you do not need to safe-keep the old node's root namespace key, because your participant namespace changes. However, for it to work a single operator must control all the contracts or all participant operators have to agree on this rewrite.

Warning: Currently this migration only works if you are migrating from an old participant node running protocol version 3. This only works for a single operator or if all other participant operators agree and follow the same steps.

First, you must recreate all parties of the old participant in the new participant, keeping the same display name, but resulting in different ids due to the new namespace key:

```
/* Disconnect the old participant from the old domain to avoid new parties or
↳ contracts being created
 * Make sure domain and the old participant are quiet before exporting the
↳ parties or the ACS
 */
participantOld.domains.disconnect(oldDomainAlias)

// Determine all parties hosted on the old participants, except for admin parties
val partiesOld =
  participantOld.ledger_api.parties
    .list()
    .filter(party =>
      party.party.toProtoPrimitive != participantOldUid.toProtoPrimitive && party.
↳ isLocal
    )

/* Allocate new parties on the new participant with the same name and
 * display name as on the old participant, but in the namespace of the
 * new participant
 */
val partyIdsOldToPartyIdsNew = partiesOld.map { partyDetailsOld =>
  val oldParty = partyDetailsOld.party
  val partyId =
    participantNew.ledger_api.parties
      .allocate(oldParty.uid.id.toProtoPrimitive, partyDetailsOld.displayName)
      .party
```

(continues on next page)

(continued from previous page)

```
oldParty -> partyId
}.toMap
```

Secondly, you should migrate your DARs to the new participant:

```
// Migrate DARs from old to new participant
utils.migrate_dars(participantOld, participantNew)
```

Finally, you need to transfer the active contracts of all the parties from the old participant to the new one and re-write the party ids mentioned in those contracts to match the new party ids. You can then connect to the new sync domain:

```
// Export the acs of the old participant
val acsOld = participantOld.ledger_api.acs.of_all(
  limit = PositiveInt.MaxValue,
  includeCreatedEventBlob = true,
)

// Connect new participant to the new sequencer
participantNew.domains.reconnect_all()

/* Create traffic on the new participant so that the repair commands will
 * pick an identity snapshot that is aware of all party allocations
 */
participantNew.health.ping(participantNew.id)

// Disconnect new participants from the domain to be able to import the ACS
participantNew.domains.disconnect_all()

// Pick a ledger create time according to the domain's clock.
val ledgerCreateTime = clock.now.toInstant

// Switch the ACS to be based on the new party ids.
val participantNewACS = utils.change_contracts_party_ids(
  partyIdsOldToPartyIdsNew,
  acsOld,
  newKmsDomainId,
  ledgerCreateTime,
  newProtocolVersion,
  withContractIdRemap,
)

// Upload ACS to new participants
File temporaryFile(prefix = s"migration-${participantNew.name}", suffix = "gz") {
  ←tempFile =>
    val outputStream = tempFile.newGzipOutputStream()
    ResourceUtil.withResource(outputStream) { s => participantNewACS.foreach(_
  ←writeDelimitedTo(s))
    outputStream.flush()
    val partiesHostedOnParticipantNew = partyIdsOldToPartyIdsNew.values.toSet
    participantNew.repair.import_acs(tempFile.canonicalPath,
  ←partiesHostedOnParticipantNew)
}

// Kill/stop the old participant
```

(continues on next page)

(continued from previous page)

```
stopOldParticipant()  
  
// Connect the new participant to the new domain  
participantNew.domains.reconnect_all()
```

The result is a new participant node, in a different namespace, with its keys stored and managed by a KMS connected to a sync domain that can communicate using the appropriate key schemes.

You need to follow the same steps if you want to migrate a node back to using a *non*-KMS provider.

32.4.3.5 Manual KMS key rotation

Canton keys, except the root namespace keys, can still be manually rotated even if they are externally stored in a KMS. To do that you can use the [standard rotate key commands](#) or, if you already have a pre-generated KMS key to rotate to, run the following command:

```
val newSigningKeyParticipant = participant1.keys.secret  
  .rotate_kms_node_key(  
    keyFingerprint,  
    newKmsKeyId,  
    "kms_key_rotated",  
  )
```

No current KMS service offers automatic rotation of asymmetric keys so the node operator needs to be responsible for periodically rotating these keys.

If you need to rotate the namespace root key then you have to follow the same [procedure](#) as migrating from a non-KMS to a KMS participant including contract rewriting.

32.4.4 Canton KMS Driver Developer Guide

Important: [Daml Enterprise license](#) required

32.4.4.1 Introduction

The Canton protocol relies on a number of cryptographic operations such as asymmetric encryption and digital signatures. To maximize the operational security of a Canton node the corresponding private keys should not be stored or processed in cleartext. A Key Management System (KMS) or Hardware Security Module (HSM) allows us to perform such cryptographic operations where the private key resides securely inside the KMS/HSM. All nodes in Canton can make use of a KMS.

AWS KMS and Google Cloud KMS are supported as of Canton v2.7. To broaden the support of other KMSs and HSMs, Canton v2.9 introduces a plugin approach, called KMS Drivers, which allows the implementation of custom integrations. This document explains the APIs that must be implemented for a KMS Driver, provides a guide on the implementation, and describes how to configure Canton to run with a KMS driver. An implementation needs to be developed for the JVM, currently only Scala is supported.

32.4.4.2 KMS Driver API

The two main APIs that are required for a KMS Driver are:

1. Driver Factory: Implements how a driver is instantiated and the main entry point for Canton to load a driver.
2. KMS Driver: The actual KMS driver API that offers cryptographic operations based on the KMS.

The stable APIs are versioned with a single major version number. A breaking change to either the factory or driver APIs will result in a new major version of those APIs. The current and only version is **v1**, which is part of the module path for the respective API interfaces.

KMS Driver Factory API v1

The factory consists of two interfaces: a generic v1 DriverFactory and a specific v1 KmsDriverFactory.

The `v1.DriverFactory` defines the following aspects for a generic driver:

The type of the driver

A name that uniquely identifies the driver

The version of the API the driver implements and optional build information (driver version number or commit hash)

A driver-specific configuration object with configuration parser and writer

A create method that instantiates a driver with that factory

Concretely the interface is defined as the following in Scala:

```
// Copyright (c) 2024 Digital Asset (Switzerland) GmbH and/or its affiliates.
// Proprietary code. All rights reserved.

package com.digitalasset.canton.driver.api.v1

import com.digitalasset.canton.driver.api
import org.slf4j.Logger
import pureconfig.{ConfigReader, ConfigWriter}

import scala.concurrent.ExecutionContext

/** The corresponding factory for an implementation of a [[Driver]] that can
  * ↪ instantiate a new driver. */
trait DriverFactory extends api.DriverFactory {

  /** The name of the driver that is instantiated by an implementation of the
  * ↪ driver factory. */
  def name: String

  /** The version of the driver API this factory is implemented against. */
  def version: Int

  /** Optional information for the build of the driver factory, e.g., git commit
  * ↪ hash. */
  def buildInfo: Option[String]

  /** The driver-specific configuration type. */
  type ConfigType
}
```

(continues on next page)

(continued from previous page)

```

/** The parser to load the driver-specific configuration. */
def configReader: ConfigReader[ConfigType]

/** The configuration writer for the driver-specific configuration.
 *
 * @param confidential If the flag is true, the config writer should omit any
→ sensitive configuration items, such as credentials.
 */
def configWriter(confidential: Boolean): ConfigWriter[ConfigType]

/** The creation method of a driver by this factory.
 * If the creation of the driver fails this method should throw an exception.
 *
 * @param config The driver-specific configuration.
 * @param loggerFactory A logger factory that should be used by the driver to
→ create a logger for a particular class.
 * @param executionContext The execution context that should be used by the
→ driver.
 *
 * @return A new instance of [[Driver]].
 */
def create(
  config: ConfigType,
  loggerFactory: Class[_] => Logger,
  executionContext: ExecutionContext,
): Driver
}

```

A specialization of the generic `DriverFactory` is the `v1.KmsDriverFactory` which defines the driver type to be a `KmsDriver` and the API version to be 1.

```

// Copyright (c) 2024 Digital Asset (Switzerland) GmbH and/or its affiliates.
// Proprietary code. All rights reserved.

package com.digitalasset.canton.crypto.kms.driver.api.v1

import com.digitalasset.canton.crypto.kms.driver.api
import com.digitalasset.canton.driver.api.v1

trait KmsDriverFactory extends api.KmsDriverFactory with v1.DriverFactory {

  override val version: Int = 1

  override type Driver <: KmsDriver
}

```

Driver Configuration Reading & Parsing

Canton uses [pureconfig](#) configuration library to read its configuration. Given that the configuration of the driver can be embedded inside a Canton configuration file, the factory of the driver needs to specify the type of configuration, as well as configuration readers and writers. A `ConfigType` can be a case class or as basic as a `Map[String, String]`. In the latter case, the config reader and writer can be defined as:

```
val configReader = pureconfig.ConfigReader.mapReader[String]
val configWriter = pureconfig.ConfigWriter.mapWriter[String]
```

KMS Driver API v1

The main part of the API is the `v1.KmsDriver` API that defines the following operations for a KMS Driver:

- Key Generation: Asymmetric signing and encryption key pairs as well as symmetric encryption keys
- Supported Key and Algorithm Specifications: The specs that are supported by the driver, for example, RSA 2048 keys and RSA OAEP SHA256 asymmetric encryption.
- Signing: Sign data with a key from the KMS and the specified algorithm.
- Asymmetric Decryption: Decrypt a ciphertext with a private key from the KMS and the specified algorithm.
- Symmetric Encryption and Decryption: Encrypt or decrypt with a symmetric encryption key from the KMS. The default symmetric encryption algorithm of the KMS is used.
- Key Management: Get the public key of a private key stored in the KMS, check if a key exists, and delete a key.
- Health: Return the health of the KMS Driver instance.

The API is designed as an asynchronous API using Futures. An OpenTelemetry trace context is passed in from Canton into the KMS driver operations to be able to link a Canton request to operations in the KMS. The driver is responsible for propagating the trace context into the KMS.

Concretely the Scala interface is defined as the following:

```
// Copyright (c) 2024 Digital Asset (Switzerland) GmbH and/or its affiliates.
// Proprietary code. All rights reserved.

package com.digitalasset.canton.crypto.kms.driver.api.v1

import com.digitalasset.canton.crypto.kms.driver.api
import io.opentelemetry.context.Context

import scala.concurrent.Future

/** The interface for a pluggable KMS implementation, that is, a KMS Driver.
 *
 * * Cryptographic operations are async, i.e., they return a Future.
 * * In case of failures, the future must be failed with a [[KmsDriverException]].
 *
 * * Each KMS operation takes an OpenTelemetry [[io.opentelemetry.context.
 * Context]] as a trace context that can optionally be propagated to the external
 * KMS.
 */
```

(continues on next page)

(continued from previous page)

```

trait KmsDriver extends api.KmsDriver with AutoCloseable {

  /** Returns the current health of the driver.
   *
   * If the driver reports itself as unhealthy, Canton will close the current
   ↪ driver instance and create a new one to recover from the unhealthy state.
   * Transient failures should be reported by throwing an [[com.digitalasset.
   ↪ canton.crypto.kms.driver.api.v1.KmsDriverException]] with `retryable` true on

final case class PublicKey(key: Array[Byte], spec: KeySpec)
```

Error Handling and Health

In case the driver experiences an error the `Future` of the operation should be failed with a `KmsDriverException`. When the exception's flag `retryable` is `true` the caller side, i.e., Canton, performs a retry with exponential backoff. This behavior is suitable for transient errors, such as network issues, resource exhaustion etc.

In case of permanent errors, a non-retryable exception should be thrown, which either fails the current operation from where the cryptographic operation is called or causes a fatal error in the Canton node.

The driver should report its health through the `health` method. A Canton node periodically queries the health of the driver and reports it as part of the node's overall health.

32.4.4.3 Develop and Test a KMS Driver

Set Up API Dependency

The Canton KMS Driver API is published as an artifact on Digital Asset's JFrog Artifactory:

<https://digitalasset.jfrog.io/ui/repos/tree/General/canton-kms-driver-api>

You must have a Canton enterprise license and account to access the artifact. You may need to configure your build system to authenticate with a personal access token towards JFrog Artifactory.

In your build system of choice, you need to depend on the API as a regular Maven-style artifact with:

```
organization: com.digitalasset.canton
artifact: kms-driver-api
version: the Canton release version, e.g., 2.9.0
```

Implement the API and Build the Driver

Implement the `v1.KmsDriverFactory` by specifying the driver's name, configuration type with readers/writers, and the `create` method to instantiate a driver by creating a new class instance of your `KmsDriver` implementation. Specify the fully qualified name of the factory class in the file:

```
src/main/resources/META-INF/services/com.digitalasset.canton.crypto.kms.
driver.api.v1.KmsDriverFactory
```

and in the following file for the base driver factory (without `v1`):

```
src/main/resources/META-INF/services/com.digitalasset.canton.crypto.kms.
driver.api.KmsDriverFactory
```

The major part of the implementation is the `v1.KmsDriver` that is specific to the KMS/HSM to be integrated with. The supported key and algorithm specifications can be defined statically depending

on the capabilities of the underlying KMS/HSM. To ensure the best compatibility with other Canton nodes, all currently specified key and algorithm specifications should be supported.

Any credentials required by the underlying KMS/HSM can either be passed through the Canton configuration file as part of the driver-specific configuration, where secrets can be resolved from the environment, or retrieved by the driver directly from the environment or any other driver-specific means.

Bundle your driver into a self-contained jar, that is, with all required libraries included in the jar. That way you only need a single driver jar when starting Canton with your KMS Driver.

KMS Driver Testing

The reusable test suite for KMS Drivers is published at [canton-kms-driver-testing](#). Configure your build system to depend on this maven artifact in the test scope of your project (e.g. for sbt append % Test to limit the dependency to the test scope).

KmsDriverTest

The main part of the test suite is the `KmsDriverTest` that tests the functionality of a driver against the `KmsDriver` API.

In the simplest form the specific driver test class extends the `KmsDriverTest` and allows the generation of new keys as part of the test:

```
class AwsKmsDriverTest extends KmsDriverTest {

  override protected def newKmsDriver(): KmsDriver = {
    val awsKms = AwsKms
      .create(KmsConfig.Aws.awsTestConfig, timeouts, loggerFactory)
      .valueOrFail("failed to create AWS KMS")

    new AwsKmsDriver(awsKms)
  }

  "AWS KMS Driver" must {
    behave like kmsDriver(allowKeyGeneration = true)
  }
}
```

Generating new keys can be expensive when running tests during development, in particular when using cloud-based KMSs. To mitigate this, the test suite can also be configured to use predefined keys to test most parts (except key generation) of the KMS Driver API:

```
class AwsKmsDriverWithPredefinedKeysTest extends KmsDriverTest {

  override val predefinedSigningKeys: Map[SigningKeySpec, String] =
    Map(
      SigningKeySpec.EcP256 -> "alias/canton-kms-test-signing-key",
      SigningKeySpec.EcP384 -> "alias/canton-kms-test-signing-key-P384",
    )
}
```

(continues on next page)

(continued from previous page)

```

override val predefinedEncryptionKeys: Map[EncryptionKeySpec, String] =
    Map(EncryptionKeySpec.Rsa2048 -> "alias/canton-kms-test-asymmetric-key")

override val predefinedSymmetricKey: Option[String] = Some("alias/canton-kms-
↳test-key")

override protected def newKmsDriver(): KmsDriver = {
    val awsKms = AwsKms
        .create(KmsConfig.Aws.awsTestConfig, timeouts, loggerFactory)
        .valueOrFail("failed to create AWS KMS")

    new AwsKmsDriver(awsKms)
}

"AWS KMS Driver" must {
    behave like kmsDriver(allowKeyGeneration = false)
}
}

```

For each supported signing/encryption key specification an existing key alias/ID can be configured as part of the predefined keys maps. When running the test suite the generation of new keys is not allowed.

KmsDriverFactoryTest

The test suite for the KMS driver factory is structured similarly to the above:

```

class AwsKmsDriverFactoryTest extends KmsDriverFactoryTest {

    override type Factory = AwsKmsDriverFactory

    override protected lazy val factory: AwsKmsDriverFactory =
        new AwsKmsDriverFactory

    override protected lazy val config: AwsKmsDriverFactory#ConfigType = {
        val aws = KmsConfig.Aws.awsTestConfig
        AwsKmsDriverConfig(region = aws.region, multiRegionKey = aws.multiRegionKey)
    }

    "AWS KMS Driver Factory" must {
        behave like kmsDriverFactory()
    }
}

```

The `KmsDriverFactory` can write the driver-specific configuration with a confidential flag being true, which means any sensitive information in the configuration such as credentials should be omitted from the written configuration. A specific test case should be added if your driver-specific configuration contains any confidential information, asserting that the sensitive information is omitted.

32.4.4.4 Run Canton with a KMS Driver

Configure Canton to run with a KMS driver, for example, for a participant `participant1`:

```
canton.participants.participant1.crypto.provider = kms
canton.participants.participant1.crypto.kms {
  type = driver
  name = "aws-kms"
  config = {
    region = us-east-1
    multi-region-key = false
    audit-logging = true
  }
}
```

Run Canton with your driver jar on its class path:

```
java -cp driver.jar:canton.jar com.digitalasset.canton.CantonEnterpriseApp
-c canton.conf # further canton arguments
```

Where `canton.jar` depends on the Canton version, e.g., `lib/canton-enterprise-2.9.0.jar`. The `canton.conf` is a configuration file that needs to configure at least one of the nodes to use the driver KMS as outlined above. Run a ping for example with `participant1.health.ping(participant1)` to validate that the participant can use the configured KMS and driver.

Chapter 33

Scaling and Performance

33.1 Network Scaling

The scaling and performance characteristics of a Canton-based system are determined by many factors. The simplest approach is to deploy Canton as a simple monolith where vertical scaling would add more CPUs, memory, etc. to the compute resource. However, the most frequent and expected deployment of Canton is as a distributed, micro-service architecture, running in different data centers of different organizations, with many opportunities to incrementally increase throughput. This is outlined below.

The ledger state in Canton does not exist globally so there is no single node that, by design, hosts all contracts. Instead, participant nodes are involved in transactions that operate on the ledger state on a strict need-to-know basis (data minimization), only exchanging (encrypted) information on the sync domains used as coordination points for the given input contracts. For example, if participants Alice and Bank transact on an i-owe-you contract on sync domain A, another participant Bob, or another sync domain B, does not receive a single bit related to this transaction. This is in contrast to blockchains, where each node has to process each block regardless of how active or directly affected they are by a given transaction. This lends itself to a micro-service approach that can scale horizontally.

The micro-services deployment of Canton includes the set of participant nodes (hereafter, `participant` or `participants`) and sync domains, as well as the services internal to the sync domain (e.g., Topology Manager). In general, each Canton micro-service follows the best practice of having its own local database which increases throughput. Deploying a service to its own compute server increases throughput because of the additional CPU and disk capacity. A vertical scaling approach can be used to increase throughput if a single service becomes a bottleneck, along with the option of horizontal scaling that is discussed next.

An initial Canton deployment can increase its scaling in multiple ways that build on each other. If a single participant node has many parties, then throughput can be increased by migrating parties off to a new, additional participant node (currently supported as a manual early access feature). For example, if 100 parties are performing multi-lateral transactions with each other, then the system can reallocate parties to 10 participants with 10 parties each, or 100 participants with 1 party each. As most of the computation occurs on the participants, a sync domain can sustain a very substantial load from multiple participants. If the sync domain were to be a bottleneck then the sequencer(s), topology manager, and mediator can be run on their own compute server which increases the sync domain throughput. Therefore, new compute servers with additional Canton nodes can be added to the network when needed, allowing the entire system to scale horizontally.

If even more throughput is needed then the multiple-sync-domain feature of Canton can be leveraged to increase throughput. In a large and active network where a sync domain reaches the capacity limit, additional sync domains can be rolled out, such that the workflows can be sharded over the available sync domains (early access). This is a standard technique for load balancing where the client application does the load balancing via sharding.

If a single party is a bottleneck then the throughput can be increased by sharding the workflow across multiple parties hosted on separate participants. If a workflow is involving some large operator (i.e. an exchange), then an option would be to shard the operator by creating two operator parties and distribute the workflows evenly over the two operators (eventually hosted on different participants), and by adding some intermediate steps for the few cases where the workflows would span across the two shards.

Some anti-patterns need to be avoided for the maximum scaling opportunity. For example, having almost all of the parties on a single participant is an anti-pattern to be avoided since that participant will be a bottleneck. Similarly, the design of the Daml model has a strong impact on the degree to which sharding is possible. For example, having a Daml application that introduces a synchronization party through which all transactions need to be validated introduces a bottleneck so it is also an anti-pattern to avoid.

The bottom line is that a Canton system can scale out horizontally if commands involve only a small number of participants and sync domains.

Important: [Daml Enterprise license](#) required

33.2 Node Scaling

The Daml Enterprise edition of Canton supports the following scaling of nodes:

The database-backed drivers (Postgres and Oracle) can run in an active-active setup with parallel processing, supporting multiple writer and reader processes. Thus, such nodes can scale horizontally.

The enterprise participant node processes transactions in parallel (except the process of conflict detection which by definition must be sequential), allowing much higher throughput than the community version. The community version processes each transaction sequentially. Canton processes make use of multiple CPUs and will detect the number of available CPUs automatically. The number of parallel threads can be controlled by setting the JVM properties `scala.concurrent.context.numThreads` to the desired value.

Generally, the performance of Canton nodes is currently storage I/O bound. Therefore, their performance depends on the scaling behavior and throughput performance of the underlying storage layer, which can be a database or a distributed ledger for some drivers. Therefore, appropriately sizing the database is key to achieving the necessary performance.

On a related note: the Daml interpretation is a pure operation, without side-effects. Therefore, the interpretation of each transaction can run in parallel, and only the conflict detection between transactions must run sequentially.

33.3 Performance and Sizing

A Daml workflow can be computationally arbitrarily complex, performing lots of computation (cpu!) or fetching many contracts (io!), and involve different numbers of parties, participants, and sync domains. Canton nodes store their entire data in the storage layer (database), with additional indexes. Every workflow and topology is different, and therefore, sizing requirements depend on the Daml application that is going to run, and on the resource requirements of the storage layer. Therefore, to obtain sizing estimates you must measure the resource usage of dominant workflows using a representative topology and setup of your use case.

33.4 Batching

As every transaction comes with an overhead (signatures, symmetric encryption keys, serialization and wrapping into messages for transport, HTTP headers, etc), we recommend designing the applications submitting commands in a way that batches smaller requests together into a single transaction.

Optimal batch sizes depend on the workflow and the topology and need to be determined experimentally.

33.5 Asynchronous Submissions

In order to achieve the best performance, we suggest that you use asynchronous command submissions. However, please note that the async submission is only partially asynchronous, as the initial command interpretation and transaction building are included in that step, while the transaction validation and result finalization are not. This means that an async submission takes between 50 to 1000 ms, depending on command size and complexity. In the extreme case with a single thread submitting transactions, this would mean that you would only achieve a rate of one command per second.

If you use synchronous command submissions, the system will wait for the entire transaction to complete, which will require even more threads. Also, please note that the synchronous command submission has a default upper limit of 256 in flight commands, which can be reconfigured using

```
canton.participants.participant1.ledger-api.command-service.max-commands-in-  
flight = 256 // default value
```

33.6 Storage Estimation

A priori storage estimation of a Canton installation is tricky. As explained above, storage usage depends on topology, payload, Daml models used, and what type of storage layer is configured. However, the following example may help you understand the storage usage for your use case:

First, a command submitted through the ledger API is sent to the participant as a serialized gRPC request.

This command is first interpreted and translated into a Daml-LF transaction. The interpreted transaction is next translated into a Canton transaction view-decomposition, which is a

privacy-preserving representation of the full transaction tree structure. A transaction typically consists of several transaction views; in the worst case, every action node in the transaction tree becomes a separate transaction view. Each view contains the full set of arguments required by that view, including the contract arguments of the input contracts. So the data representation can be multiplied quite a bit. Here, we cannot estimate the resulting size without having a concrete example. For simplicity, let us consider the simple case where a participant is exercising a simple `Transfer` choice on an typical `IOU` contract to a new owner, preserving the other contract arguments. We assume that the old and new owners of the IOU are hosted on the same participant whereas the IOU issuer is hosted on a second participant.

The resulting Canton transaction consists of two views (one for the **Exercise** node of the `Transfer` choice and one for the **Create** node of the transferred IOU). Both views contain some metadata such as the package and template identifiers, contract keys, stakeholders, and involved participants. The view for the **Exercise** node contains the contract arguments of the input IOU, say of size Y . The view for the **Create** node contains the updated contract arguments for the created contract, again of size Y . Note that there is no fixed relation between the command size X and the size of the input contracts Y . Typically X only contains the receiver of the transfer, but not the contract arguments that are stored on the ledger.

Then, we observe the following storage usage:

- Two encrypted envelopes with payload Y each, one view seed per view, one symmetric key per informee group, two root hashes for each participant and the participant IDs as recipients at the sequencer store, and the informee tree for the mediator (informees and transaction metadata, but no payload), together with the sequencer database indexes.

- Two encrypted envelopes with payload Y each and the symmetric keys for the views, in the participant events table of each participant (as both receive the data)

- Decrypted new resulting contract of size Y in the private contract store and some status information of that contract on the active contract journal of the sync service.

- The full decrypted transaction with a payload of size Y for the created contract, in the sync service linear event log. This transaction does not contain the input contract arguments.

- The full decrypted transaction with Y in the indexer events table, excluding input contracts, but including newly divulged input contracts.

If we assume that payloads dominate the storage requirements, we conclude that the storage requirement is given by the payload multiplication due to the view decomposition. In our example, the transaction requires $5*Y$ storage on each participant and $2*Y$ on the sequencer. For the two participants and the sequencer, this makes $12*Y$ in total.

Additionally to this, some indexes have to be built by the database to serve the contracts and events efficiently. The exact estimation of the size usage of such indexes for each database layer is beyond the scope of our documentation.

Note: Please note that we do have plans to remove the storage duplication between the sync service and the indexer. Ideally, will be able to reduce the storage on the participant for this example from $5*Y$ down to $3*Y$: once for the unencrypted created contract and twice for the two encrypted transaction views.

Generally, to recover used storage, a participant and a domain can be pruned. Pruning is available on Canton Enterprise through a [set of console commands](#) and allows removal of past events and archived contracts based on a timestamp. The storage usage of a Canton deployment can be kept constant by continuously removing obsolete data. Non-repudiation and auditability of the unpruned history are preserved due to the bilateral commitments.

33.7 Set Up Canton to Get the Best Performance

In this section, the findings from internal performance tests are outlined to help you achieve optimal performance for your Canton application.

33.7.1 System Design / Architecture

We recommend the version of Canton included in the Daml Enterprise edition, which is heavily optimized when compared with the community edition.

Plan your topology such that your Daml parties can be partitioned into independent blocks. That means most of your Daml commands involve parties of a single block only. It is ok if some commands involve parties of several (or all) blocks, as long as this happens only very rarely. In particular, avoid having a single master party that is involved in every command, because that party bottlenecks the system.

If your participants are becoming a bottleneck, add more participant nodes to your system. Make sure that each block runs on its own participant. If your domain(s) are becoming a bottleneck, add more domain nodes and distribute the load evenly over all domains.

Prefer sending big commands with multiple actions (creates / exercises) over sending numerous small commands. Avoid sending unnecessary commands through the ledger API. Try to minimize the payload of commands.

Further information can be found in Section [Scaling and Performance](#).

33.7.2 Hardware and Database

Do not run Canton nodes with an in-memory storage or with an H2 storage in production or during performance tests. You may observe very good performance in the beginning, but performance can degrade substantially once the data stores fill up.

Measure memory usage, CPU usage and disk throughput and improve your hardware as needed. For simplicity, it makes sense to start on a single machine. Once the resources of a machine are becoming a bottleneck, distribute your nodes and databases to different machines.

Try to make sure that the latency between a Canton node and its database is very low (ideally in the order of microseconds). The latency between Canton nodes has a much lower impact on throughput than the latency between a Canton node and its database.

Please check the [Postgres persistence section](#) for tuning instructions.

33.7.3 Configuration

In the following, we go through the parameters with known impact on performance.

Timeouts. Under high load, you may observe that commands timeout. This will negatively impact throughput, because the commands consume resources without contributing to the number of accepted commands. To avoid this situation increase timeout parameters from the Canton console:

```
myDomain.service.update_dynamic_domain_parameters(
  _update(
    participantResponseTimeout = 60.seconds,
    mediatorReactionTimeout = 60.seconds
  )
)
```

If timeouts keep occurring, change your setup to submit commands at a lower rate. In addition, take the next paragraph on resource limits into account.

Tune resource limits at the Canton protocol level. Resource limits are used to prevent ledger applications from overloading Canton by sending commands at an excessive rate. While resource limits are necessary to protect the system from denial of service attacks in a production environment, they can prevent Canton from achieving maximum throughput. Resource limits at the Canton protocol level can be configured as follows from the Canton console:

```
participant1.resources.set_resource_limits(
  ResourceLimits(
    // Allow for submitting at most 200 commands per second
    maxRate = Some(200),

    // Limit the number of in-flight requests to 500.
    // A "request" includes every transaction that needs to be validated by
    ↪ participant1:
    // - transactions originating from commands submitted to participant1
    // - transaction originating from commands submitted to different
    ↪ participants.
    // The chosen configuration allows for processing up to 100 requests per
    ↪ second
    // with an average latency of 5 seconds.
    maxDirtyRequests = Some(500),

    // Allow submission bursts of up to `factor * maxRate`
    maxBurstFactor = 0.5,
  )
)
```

As a rule of thumb, configure `maxDirtyRequests` to be slightly larger than `throughput * latency`, where

`throughput` is the number of requests per second Canton needs to handle and
`latency` is the time taken to process a single request while Canton is receiving requests at
`rate throughput`.

You should run performance tests to ensure that `throughput` and `latency` are actually realistic. Otherwise, an application may overload Canton by submitting more requests than Canton can handle.

Configure the `maxRate` parameter to be slightly higher than the expected maximal throughput.

If you need to support command bursts, configure the `maxBurstFactor` accordingly. Then, the `maxRate` limitation will only start to enforce the rate after having received the initial burst of `maxBurstFactor * maxRate`.

To find optimal resource limits you need to run performance tests. The `maxDirtyRequest` parameter will protect Canton from being overloaded, if requests are arriving at a constant rate. The `maxRate` parameter offers additional protection, if requests are arriving at a variable rate.

If you choose higher resource limits, you may observe a higher throughput, at the risk of a higher latency. In the extreme case however, latency grows so much that commands will timeout; as a result, the command processing consumes resources even though some commands are not committed to the ledger.

If you choose lower resource limits, you may observe a lower latency, at the cost of lower throughput and commands getting rejected with the error code `PARTICIPANT_BACKPRESSURE`.

Tune resource limits at the ledger API level. Resource limits can also be imposed on the ledger API level. As these settings are applied closer to the ledger applications, they can be used for protecting the resources of individual participants rather than the entire Canton system.

You can modify the following configuration options:

```
canton.participants.<participant-name>.ledger-api.rate-limit {  
  max-streams = 333  
  max-api-services-queue-size = 444  
  max-api-services-index-db-queue-size = 555  
  max-used-heap-space-percentage = 66  
  min-free-heap-space-bytes = 777777  
}
```

You can cap the number of ledger API gRPC streams open at any given time by modifying the `max-streams` parameter. When the number of simultaneously open transaction, transaction-tree, completion, or acs streams reaches the maximum, it doesn't accept any additional get stream requests and returns a `MAXIMUM_NUMBER_OF_STREAMS` error code instead.

You can cap the number of items pending in the thread pools serving the Ledger API and the index database read requests by modifying the `max-api-services-queue-size` and `max-api-services-index-db-queue-size` respectively. When the CPU worker thread pool or the database communication thread pool is overloaded, the server responds with a `THREADPOOL_OVERLOADED` error code.

You can cap the percentage of the memory heap used by changing the `max-used-heap-space-percentage` parameter. If this percentage is exceeded following a garbage collection of the tenured memory pool, the system is rate-limited until additional space is freed up.

Similarly, you can set the minimum heap space in absolute terms by changing the `min-free-heap-space-bytes` parameter. If the amount of free space is below this value following a garbage collection of the tenured memory pool, the system is rate-limited until additional space is freed up. When the maximum memory thresholds are exceeded the server responds to ledger API requests with a `HEAP_MEMORY_OVER_LIMIT` error code.

The following configuration values are the defaults:

```
max-streams = 1000  
max-api-services-queue-size = 10000  
max-api-services-index-db-queue-size = 1000  
max-used-heap-space-percentage = 100  
min-free-heap-space-bytes = 0
```

The memory-related settings of 100 for `max-used-heap-space-percentage` and 0 for `min-free-heap-space-bytes` render them effectively inactive. This is done on purpose. They are highly sensitive to the operating environment and should only be configured where memory profiling has highlighted spikes in memory usage that need to be flattened.

It is possible to turn off rate limiting at the ledger API level:

```
canton.participants.<participant-name>.ledger-api {
  rate-limit = null
}
```

Size of connection pools. Make sure that every node uses a connection pool to communicate with the database. This avoids the extra cost of creating a new connection on every database query. Canton chooses a suitable connection pool by default, but for performance sensitive applications you may want to optimize. Configure the maximum number of connections such that the database is fully loaded, but not overloaded. Allocating too many database connections will lead to resource waste (each thread costs), context switching and contention on the database system, slowing the overall system down. If this occurs, the query latencies reported by Canton go up ([check the troubleshooting guide](#)).

Detailed instructions on handling this issue can also be found in [Max Connection Settings](#).

Size of database task queue. If you are seeing frequent `RejectedExecutionExceptions` when Canton queries the database, increase the size of the task queue, as described in [Database task queue full](#). The rejection is otherwise harmless. It just points out that the database is overloaded.

Database Latency. Ensure that the database latency is low. The higher the database latency, the lower the actual bandwidth and the lower the throughput of the system.

Throttling configuration for SequencerClient. The `SequencerClient` is the component responsible for managing the connection of any member (participant, mediator, or topology manager) in a Canton network to the domain. Each domain can have multiple sequencers, and the `SequencerClient` connects to one of them. However, there is a possibility that the `SequencerClient` can become overwhelmed and struggle to keep up with the incoming messages. To address this issue, a configuration parameter called `maximum-in-flight-event-batches` is available:

```
domain-managers {
  domainManager1 {
    sequencer-client.maximum-in-flight-event-batches = 100
  }
}
participants {
  participant1 {
    sequencer-client.maximum-in-flight-event-batches = 100
  }
  participant2 {
    sequencer-client.maximum-in-flight-event-batches = 100
  }
}
mediators {
  mediator1 {
    sequencer-client.maximum-in-flight-event-batches = 100
  }
}
sequencers {
  sequencer1 {
    sequencer-client.maximum-in-flight-event-batches = 100
  }
}
```

By setting the `maximum-in-flight-event-batches` parameter, you can control the maximum number of event batches that the system processes concurrently. This configuration helps prevent

overload and ensures that the system can handle the workload effectively.

It's important to note that the value you choose for `maximum-in-flight-event-batches` impacts the `SequencerClient`'s performance in several ways. A higher value can potentially increase the `SequencerClient`'s throughput, allowing it to handle more events simultaneously. However, this comes at the cost of higher memory consumption and longer processing times for each batch.

On the other hand, a lower value for `maximum-in-flight-event-batches` might limit the throughput, as it can process fewer events concurrently. However, this approach can result in more stable and predictable `SequencerClient` behavior.

To monitor the performance of the `SequencerClient` and ensure it is operating within the desired limits, you can observe the metric `sequencer-client.handler.actual-in-flight-event-batches`. This metric provides the current value of the in-flight event batches, indicating how close it is to the configured limit. Additionally, you can also reference the metric `sequencer-client.handler.max-in-flight-event-batches` to determine the configured maximum value.

By monitoring these metrics, you can gain insights into the actual workload being processed and assess whether it is approaching the specified limit. This information is valuable for maintaining optimal `SequencerClient` performance and preventing any potential bottlenecks or overload situations.

Turn on High-Throughput Sequencer. The database sequencer has a number of parameters that can be tuned. The trade-off is low-latency or high-throughput. In the low-latency setting, every submission will be immediately processed as a single item. In the high-throughput setting, the sequencer will accumulate a few events before writing them together at once. While the latency added is only a few ms, it does make a difference during development and testing of your Daml applications. Therefore, the default setting is `low-latency`. A production deployment with high throughput demand should choose the `high-throughput` setting by configuring:

```
// example setting for domain nodes. database sequencer nodes have the exact same
↪settings.
canton.domains.mydomain.sequencer {
  type = database
  writer = {
    // choose between high-throughput or low-latency
    type = high-throughput
  }
}
```

There are additional parameters that can in theory be fine-tuned, but we recommend to leave the defaults and use either high-throughput or low-latency. In our experience, a high-throughput sequencer can handle several thousand submissions per second.

JVM heap size. In case you observe `OutOfMemoryErrors` or high overhead of garbage collection, you must increase the heap size of the JVM, as described in Section [Java Virtual Machine Arguments](#). Use tools of your JVM provider (such as VisualVM) to monitor the garbage collector to check whether the heap size is tight.

Size of thread pools. Every Canton process has a thread pool for executing internal tasks. By default, the size of the thread-pool is configured as the number of (virtual) cores of the underlying (physical) machine. If the underlying machine runs other processes (e.g., a database) or if Canton runs inside of a container, the thread-pool may be too big, resulting in excessive context switching. To avoid that, configure the size of the thread pool explicitly like this:

```
"bin/canton -Dscala.concurrent.context.numThreads=12 --config examples/01-simple-
↳topology/simple-topology.conf"
```

As a result, Canton will log the following line:

```
"INFO c.d.c.e.EnterpriseEnvironment - Deriving 12 as number of threads from '-
↳Dscala.concurrent.context.numThreads'."
```

Asynchronous commits. If you are using a Postgres database, configure the participant's ledger API server to commit database transactions asynchronously by including the following line into your Canton configuration:

```
canton.participants.participant1.ledger-api.postgres-data-source.synchronous-
↳commit = off
```

Logging Settings. Make sure that Canton outputs log messages only at level INFO and above and turn off immediate log flushing using the `--log-immediate-flush=false` commandline flag, at the risk of missing log entries during a host system crash.

Replication. If (and **only if**) using single nodes for participant, sequencer, and/or mediator, replication can be turned off by setting `replication.enabled = false` in their respective configuration.

Warning: While replication can be turned off to try to obtain performance gains, it must **not** be disabled when running multiple nodes for HA.

Caching Configuration. In some cases, you might also want to tune caching configurations and either reduce or increase them, depending on your situation. This can also be helpful if you need to reduce the memory foot-print of Canton, which can be large, as the default cache configurations are tailored for high-throughput, high-memory and small transaction sizes.

Generally, the caches that usually matter with respect to size are the contract caches and the in-memory fan-out event buffer. You can tune these using the following configurations. The values depicted here are the ones recommended for smaller memory-footprints and are therefore also helpful if you run into out-of-memory issues:

```
canton.participants.participant1 {
  // tune caching configs of the ledger api server
  ledger-api {
    index-service {
      max-contract-state-cache-size = 1000 // default 1e4
      max-contract-key-state-cache-size = 1000 // default 1e4

      // The in-memory fan-out will serve the transaction streams from
↳memory as they are finalized, rather than
      // using the database. Therefore, you should choose this buffer to be
↳large enough such that the likeliness of
      // applications having to stream transactions from the database is
↳low. Generally, having a 10s buffer is
      // sensible. Therefore, if you expect e.g. a throughput of 20 tx/s,
↳then setting this number to 200 is sensible.
      // The default setting assumes 100 tx/s.
      max-transactions-in-memory-fan-out-buffer-size = 200 // default 1000
```

(continues on next page)

(continued from previous page)

```

    }
  }
  // tune the synchronisation protocols contract store cache
  caching {
    contract-store {
      maximum-size = 1000 // default 1e6
      expire-after-access = 120s // default 10 minutes
    }
  }
}

```

33.8 Model Tuning

How you write your Daml model has a large impact on the performance of your system. There are instances of good models running with 3000 ledger events/second (v2.7) on a single participant node. A bad model will reach a fraction of that. Therefore, it is important to understand the connection between the model and the performance implications. This section aims to give a few guidelines.

33.8.1 Reduce the Number of Views

One key performance driver in Canton is the transaction structure resulting from the model. A Daml command is effectively a `program` that computes a transaction structure. This transaction structure is then broken up by Canton into pieces called `transaction views`. The transaction views are then encrypted and sent to the participants who then confirm each view. Each view requires cryptography and creates additional payload that needs to be processed and validated.

As a result, the performance of your system directly depends on how many views the transaction creates. The number of views of a transaction is logged on the participant side as a `DEBUG` log message:

```
Computed transaction tree with total=27 for #root-nodes=8
```

If you submit a ledger API command (which can have multiple Daml commands), then every Daml command will create one so-called root-node, (two for the `CreateAndExercise` command). Each root node creates one view.

Just putting all Daml commands into a single batch command does not help, as you might still create lots of views.

33.8.1.1 Strategy for Protocol Version 7

Starting from protocol version 7, Canton creates a view for every action node in the transaction tree if the **participants that host their informees are not a subset of their parent view's informee participants**. A view's informee participants are all the participants that must be informed about the view. Therefore, to reduce the number of views, you should try to reduce either the number of times the set of informees grows or make sure most of your actions share the same pool of participants. Alternatively, you can add informees to the action nodes close to the root (e.g., by including choice observers) so that their children nodes are aggregated in the initial view, since these children nodes target only a subset of those participants.

One concrete way to reduce the number of views being generated by a Daml model is to write batch commands and group the operations on the ledger based on their informees' participants. In other words, you can create a single choice and batch all the operations that share the same informee participant group.

You can also reduce the number of views being generated for the children of a node (i.e., parent-child views) when creating your Daml model. With the below example as reference, instead of sending a batch with 20 exercise commands `Foo`, you can group your contracts by a set of stakeholders that cover the exercise's informee participants and send one exercise command on a generator contract with the list of contracts that in turn exercises the `Foo` choice per stakeholder group. This way you can perform these operations in a single view, instead of having them spawn multiple different views.

For example, if the `doUpdate` below is called from a choice visible to the owner party alone, then whether the `efficient` flag is set or not has a huge impact on the number of views created. In the choice `Foo` of the `Example` contract, even though the participants to be informed are a subset of the contract's informee participants they are not merged into a single view if this choice is called independently each time. On the contrary, you will produce multiple root actions each belonging to their own view. Finally, aligning the choice observer of `Run` to its template contract means that either the choice observer is the same in each case or the new observer is hosted by any of the contract's informee participants.

```
doUpdate : Bool -> Party -> Party -> [ContractId Example] -> Update ()

doUpdate efficient owner obs batch = do
  if efficient then do
    batcher <- create BatchFoo with owner
    -- This only works out if obs is the same observer on all the exercised
    ↪ Example contracts
    batcher `exercise` Run with batch = batch; obs = obs
  else do
    -- Canton will create one view per exercise
    forA_batch (`exercise` Foo)
    pure ()

template Example with
  owner : Party
  obs : Party
where
  signatory owner
  observer obs

  choice Foo : ()
    controller owner
    do
      return ()

template BatchFoo with
  owner : Party
where
  signatory owner

  choice Run : () with
    batch : [ContractId Example]
    obs : Party
    -- The observer here is a choice observer. Therefore, Canton will
    -- ship a single view with the top node of this choice if the observer of
    ↪ the
```

(continues on next page)

(continued from previous page)

```
-- choice aligns with the observer of the contract.  
observer obs  
controller owner  
do  
  forA_ batch (`exercise` Foo)
```

As a rule, the number of views should depend on the number of groups of informee participants you have in your batch choice, not the number of batches you process in parallel within one command. An informee's participants group is formed by aggregating the participants that host each stakeholder, or in other words, the set of participants that need to see a particular view.

The informees for the different type of transaction tree nodes are (also see [Projections](#)):

- create: signatories, observers
- consuming exercise: signatories, observers, stakeholders of the choice (controller, choice observers)
- nonconsuming exercise: signatories, stakeholders of the choice (controller, choice observers), but not the observers of the contract
- fetch: signatories + actors of the fetch, which are all stakeholders which are in the authorization context that the fetch executed in
- lookupByKey: only key maintainers

33.8.1.2 Strategy for Protocol Versions 5 and Lower

For protocol versions 5 and lower, Canton creates a view for every action node in the transaction tree if the informees or confirming parties change between the node and its parent. Therefore, in order to minimize the number of views, minimize the number of changes of informees and confirming parties.

When compared with the decomposition strategy for protocol version 7, this view decomposition is more granular, with more views created, and thus less performant, since the condition to merge an action node in a view is more restricted. In this case, we only consider the lists of informees and confirming parties and any change to these lists spawns a new view.

To batch, group the operations on the ledger based solely on the lists of informees and confirming parties. You can use choice observers to align informees if necessary. With the previous model as reference, the batch function can only reduce the total number of views if the observer of the aggregating choice is the same as the *Example* contract observer.

33.8.2 Reduce Ledger Events

The best optimisation is always to just not do something. A ledger is meant to store relevant data and coordinate different parties. If you use the ledger as processing queue, you run into performance issues, as each transaction view is cryptographically secured and processed extensively to ensure privacy and integrity, which is unnecessary for intermediate steps. The rule is: if the output of a transaction submitted by a party is immediately consumed by the same party, then you are using the ledger as a processing queue. Instead, restructure your command such that the two steps happen as one.

Furthermore, each *create* creates a contract, causing data to be written to the ledger. Each *fetch* causes the interpreter to halt interpretation, asking the ledger for a contract, which in the worst case requires a lookup in the database. As the interpretation must happen sequentially, this means

a one-by-one lookup of contracts, causing load and latency. Fetching data is important and a key feature, but you should apply the same reasoning as you would for a database: A database lookup is expensive and should only be done if necessary, ideally caching repetitive computing results.

As an example, if you have a high throughput process that always resolves some data by a chain $A \rightarrow B \rightarrow C \rightarrow D$ (four fetches), then change your model to use a single cache contract $ABCD$, only fetch that contract and ensure that there is a process that whenever one of the contracts changes, $ABCD$ is updated.

Also, avoid unnecessary transient contracts, as they may cause additional views. `createAndExercise` is not a single command, but translated to one create and an exercise. Use a *nonconsuming* choice instead, possibly with a choice observer if you need to leave a trace on the ledger for audit purposes.

Generally, using `lookupKey` is also discouraged. If you use `lookupByKey` for on-ledger deduplication, the lookup requires a database lookup, as the `lookupByKey` will resolve to `None` in most cases. Instead, use command deduplication on the Ledger API. Second, the current `lookupByKey` will not be supported in a multi-domain deployment, as the current semantic only works on a single-domain deployment and can not be translated 1:1 to multi-domain.

Chapter 34

Advanced Ledger Operations

34.1 Manage Synchronization Domains

34.1.1 Permissioned Synchronization Domains

Important: [Daml Enterprise license](#) required

Canton as a network is an open virtual shared ledger. Whoever runs a Canton participant node is part of the same virtual shared ledger. However, the network itself is made up of sync domains that are used by participants to run the Canton protocol and communicate to their peers. Such sync domains can be *open*, allowing any participant with access to a sequencer node to enter and participate in the network. But sync domains can also be **permissioned**, where the operator of the sync domain topology managers needs to explicitly add the participant to the allow-list before the participant can register with a sync domain.

While the Canton architecture is designed to be resilient against malicious participants, there can never be a guarantee that the implementation of said architecture is absolutely secure. Therefore, it makes sense for most networks to impose control on which participant can be part of the network.

The first layer of control is given by securing access to the public API of the sequencers in the network. This can be done using standard network tools such as firewalls and virtual private networks.

The second layer of control is given by setting the appropriate configuration flag of the sync domain manager (or sync domain):

```
canton.domain-managers.domainManager1 {  
  topology.open = false  
  domain-parameters.protocol-version = 7  
}
```

Assuming we have set up a sync domain with this flag turned off, the config for that particular sync domain would read:

```
@ val config = DomainConnectionConfig("mydomain", sequencer1.sequencerConnection)  
config : DomainConnectionConfig = DomainConnectionConfig(  
  domain = Domain 'mydomain',  
  sequencerConnections = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(  
    (continues on next page)
```

(continued from previous page)

```

endpoints = http://127.0.0.1:30171,
transportSecurity = false
..

```

When a participant attempts to join the sync domain, it will be rejected:

```

@ participant1.domains.register(config)
ERROR com.digitalasset.canton.integration.EnterpriseEnvironmentDefinition$$anon$3
↳ Request failed for participant1.
   GrpcRequestRefusedByServer: FAILED_PRECONDITION/PARTICIPANT_IS_NOT_ACTIVE(9,
↳ a7692cc8): The participant is not yet active
   Request: RegisterDomain(DomainConnectionConfig(
     domain = Domain 'mydomain',
     sequencerConnections = Sequencer 'DefaultSequencer' ->
↳ GrpcSequencerConnection(endpoints = http://127.0.0.1:30171, transportSecurity =
↳ false),
     manualConnect = false
  ))
   CorrelationId: a7692cc868a0e8e52b8f5cf900db6398
   Context: HashMap(participant -> participant1, test ->
↳ ManagePermissionedDomainsDocumentationManual, serverResponse -> Domain Domain
↳ 'mydomain' has rejected our on-boarding attempt, domain -> mydomain, tid ->
↳ a7692cc868a0e8e52b8f5cf900db6398)
   Command ParticipantAdministration$domains$.register invoked from cmd10000006.
↳ sc:1

```

In order to allow the participant to join the sync domain, we must first actively enable it on the topology manager. We assume now that the operator of the participant *extracts its id* into a string:

```

@ val participantAsString = participant1.id.toProtoPrimitive
participantAsString : String =
↳ "PAR::participant1::122076b9ec0078f78611818a78af772ae6e0c029f55d16808868ba4b37fd7e379e07
↳ "

```

and communicates this string to the operator of the sync domain topology manager:

```

@ val participantIdFromString = ParticipantId.
↳ tryFromProtoPrimitive(participantAsString)
participantIdFromString : ParticipantId = PAR::participant1::122076b9ec00...

```

This topology manager can now add the participant by enabling it:

```

@ domainManager1.participants.set_state(participantIdFromString,
↳ ParticipantPermission.Submission, TrustLevel.Ordinary)

```

Note that the participant is not active yet:

```

@ domainManager1.participants.active(participantIdFromString)
res5: Boolean = false

```

So far, what we've done with setting the state is to issue a sync domain trust certificate, where the sync domain topology manager declares that it trusts the participant enough to become a participant of the sync domain. We can inspect this certificate using:

```
@ domainManager1.topology.participant_domain_states.list(filterStore="Authorized
↪").map(_.item)
res6: Seq[ParticipantState] = Vector(
  ParticipantState(
    From,
    domainManager1::122003395f10...,
    PAR::participant1::122076b9ec00...,
    Submission,
    Ordinary
  )
)
```

In order to have the participant become active on the sync domain, we need to register the signing keys and the `sync domain trust certificate` of the participant. The certificate is generated by the participant automatically and sent to the sync domain during the initial handshake.

We can trigger that handshake again by attempting to reconnect to the sync domain:

```
@ participant1.domains.reconnect_all()
```

Now, we can check that the participant is active:

```
@ domainManager1.participants.active(participantIdFromString)
res8: Boolean = true
```

We can also observe that we now have both sides of the sync domain trust certificate, the `From` and the `To`:

```
@ domainManager1.topology.participant_domain_states.list(filterStore="Authorized
↪").map(_.item)
res9: Seq[ParticipantState] = Vector(
  ParticipantState(
    From,
    domainManager1::122003395f10...,
    PAR::participant1::122076b9ec00...,
    Submission,
    Ordinary
  ),
  ParticipantState(
    To,
    domainManager1::122003395f10...,
    PAR::participant1::122076b9ec00...,
    Submission,
    Ordinary
  )
)
```

Finally, the participant is healthy and can use the sync domain:

```
@ participant1.health.ping(participant1)
res10: Duration = 1796 milliseconds
```

34.1.2 Synchronization Domain Rules

Every sync domain has its own rules in terms of what parameters are used by the participants while running the protocol. The participants obtain these parameters before connecting to the sync domain. They can be configured using the specific parameter section. An example would be:

```
init.domain-parameters {
  // example setting
  unique-contract-keys = yes
}
```

The full set of available parameters can be found in the [scala reference documentation](#).

34.1.3 Dynamic synchronization domain parameters

In addition to the parameters that are specified in the configuration, some parameters can be changed at runtime (i.e., while the sync domain is running); these are called **dynamic sync domain parameters**. When the sync domain is bootstrapped, default values are used for the dynamic sync domain parameters. They can be changed subsequently using the console commands described below.

A participant can get the current parameters on a sync domain it is connected to using the following command:

```
mydomain.service.get_dynamic_domain_parameters
```

Parameters that were transitioned from static to dynamic with protocol version 4 need to be retrieved individually:

```
mydomain.service.get_reconciliation_interval
mydomain.service.get_max_rate_per_participant
mydomain.service.get_max_request_size
mydomain.service.get_mediator_deduplication_timeout
```

Dynamic parameters can be set individually using:

```
mydomain.service.set_reconciliation_interval(5.seconds)
mydomain.service.set_max_rate_per_participant(100)
mydomain.service.set_max_request_size(100000)
mydomain.service.set_mediator_deduplication_timeout(2.minutes)
```

Alternatively, several can be set at the same time:

```
mydomain.service.update_dynamic_domain_parameters(
  _.update(
    participantResponseTimeout = 10.seconds,
    topologyChangeDelay = 1.second,
  )
)
```

Note: When increasing *max request size*, the sequencer nodes need to be restarted for the new value to be taken into account. If the sync domain is not distributed, it means that the sync domain node needs to be restarted.

34.1.4 Recover From a Small Max Request Size

`MaxRequestSize` is a dynamic parameter starting from protocol version 4. This parameter configures both the gRPC channel size on the sequencer node and the maximum size that a sequencer client is allowed to transfer.

If the parameter is set to a very small value (roughly under 30kb), Canton can crash because all messages are rejected by the sequencer client or by the sequencer node. This cannot be corrected by setting a higher value within the console, because this change request needs to be sent via the sequencer and will also be rejected.

To recover from this crash, you need to configure `override-max-request-size` on both the sequencer node and the sequencer clients.

On a non-distributed deployment, this means modifying both the sync domain and the participant configuration as follows:

```
domains {
  da {
    # overrides the maxRequestSize in bytes on the sequencer node
    public-api.override-max-request-size = 30000
    sequencer-client.override-max-request-size = 30000
  }
}
participants {
  participant1 {
    sequencer-client.override-max-request-size = 30000
  }
  participant2 {
    sequencer-client.override-max-request-size = 30000
  }
}
```

On a distributed deployment, for each sync domain entity deployed on its own node, you will need to override the `max-request-size` as follows:

```
domain-managers {
  domainManager1 {
    sequencer-client.override-max-request-size = 30000
  }
}
participants {
  participant1 {
    sequencer-client.override-max-request-size = 30000
  }
  participant2 {
    sequencer-client.override-max-request-size = 30000
  }
}
mediators {
  mediator1 {
    sequencer-client.override-max-request-size = 30000
  }
}
sequencers {
  sequencer1 {
    # overrides the maxRequestSize in bytes on the sequencer node
```

(continues on next page)

(continued from previous page)

```
public-api.override-max-request-size = 30000
sequencer-client.override-max-request-size = 30000
}
}
```

After the configuration is modified, disconnect all the participants from the sync domain and then restart all nodes.

On a non-distributed deployment, you can stop Canton by following these steps:

```
participants.all.domains.disconnect(da.name)
nodes.local.stop()
```

On a distributed deployment, you can stop Canton by following these steps:

```
participants.all.domains.disconnect(sequencer1.name)
nodes.local.stop()
```

Then perform the restart:

```
nodes.local.start()
participants.all.domains.reconnect_all()
```

Once Canton has recovered, use the admin command to set the *maxRequestSize* value, then delete the added configuration in the previous step, and finally perform the restart again.

34.2 Manage Synchronization Domain Entities

34.2.1 Manual vs Automatic Initialization

If you're running a sync domain in its default configuration as shown previously, it will have a sequencer and mediator embedded and these components will be automatically bootstrapped for you.

However, there are situations where a node should not be automatically initialized, but where you prefer to control each step of the initialization. For example, this might be the case when a node in the setup does not control its own identity, when you do not want to store the identity key on the node for security reasons, or when you want to set your own keys (e.g. when keys are externally stored in a Key Management Service - KMS).

If you want to disable the automatic initialization of domain nodes you have to set:

```
<node>.init.auto-init = false
```

This is only applicable for `domain/domain-manager` nodes.

34.2.2 Keys Initialization

When manual initialization is enabled, cryptographic keys in the nodes are not automatically generated and registered in Canton. The following command manually generates a Canton signing key.

```
<node>.keys.secret.generate_signing_key(<key_name>)
```

If you are using a Key Management Service (KMS) to handle Canton's keys and you want to use a set of pre-generated keys you must use instead the following command.

```
node.keys.secret.register_kms_signing_key(<kms_key_id>, <key_name>)
```

Please refer to [External Key Storage with a Key Management Service \(KMS\)](#) for more details.

Note: The following sections assume that you are using Canton keys and that you do not have a KMS set-up. If you are running your environment with KMS and want to provide your own keys, replace all instances of `generate_signing_key()` by the correct `register_kms_signing_key()` command.

34.2.2.1 Embedded Synchronization Domain Initialization

The following steps describe how to manually initialize an embedded sync domain node, where the domain manager, the sequencer and mediator are aggregated into a single entity and deployed together.

```
// first, let's create a signing key that is going to control our identity
val identityKey =
  if (useKms) {
    mydomain.keys.secret.register_kms_signing_key(
      kmsKeyId = identityKmsKeyId,
      name = mydomain.name + "-namespace",
    )
  } else {
    mydomain.keys.secret.generate_signing_key(name = mydomain.name + "-namespace")
  }

// create a signing key for this entity
val signingKey =
  if (useKms) {
    mydomain.keys.secret.register_kms_signing_key(
      kmsKeyId = signingKmsKeyId,
      name = mydomain.name + "-signing",
    )
  } else {
    mydomain.keys.secret.generate_signing_key(name = mydomain.name + "-signing")
  }

val namespace = identityKey.fingerprint

// initialise the identity of this domain
val uid = mydomain.topology.init_id(identifier = mydomain.name, fingerprint = □
↪ namespace)
```

(continues on next page)

(continued from previous page)

```

// create the root certificate for this namespace
mydomain.topology.namespace_delegations.authorize(
  ops = TopologyChangeOp.Add,
  namespace = namespace,
  authorizedKey = namespace,
  isRootDelegation = true,
)

val protocolVersion = mydomain.config.init.domainParameters.initialProtocolVersion

// set the initial dynamic domain parameters for the domain
mydomain.topology.domain_parameters_changes
  .authorize(
    domainId = DomainId(uid),
    newParameters = com.digitalasset.canton.admin.api.client.data.
    ↪DynamicDomainParameters
      .defaultValues(protocolVersion),
    protocolVersion = protocolVersion,
  )

val mediatorId = MediatorId(uid)
Seq[Member] (DomainTopologyManagerId(uid), SequencerId(uid), mediatorId).foreach {
  ↪keyOwner =>
    // in this case, we are using an embedded domain. therefore, we initialise all
    ↪domain
    // entities at once. in a distributed setup, the process needs to be invoked on
    // the separate entities, and therefore requires a bit more coordination.
    // however, the steps remain the same.

    // then, create a topology transaction linking the entity to the signing key
    mydomain.topology.owner_to_key_mappings.authorize(
      ops = TopologyChangeOp.Add,
      keyOwner = keyOwner,
      key = signingKey.fingerprint,
      purpose = KeyPurpose.Signing,
    )
}

// Register the mediator
mydomain.topology.mediator_domain_states.authorize(
  ops = TopologyChangeOp.Add,
  domain = mydomain.id,
  mediator = mediatorId,
  side = RequestSide.Both,
)

```

34.2.3 Set up a Distributed Synchronization Domain With a Single Console

If your sync domain operates with external sequencers and mediators, you will need to configure a sync domain manager node (which only runs topology management) and bootstrap your sync domain with at least one external sequencer node and one external mediator node.

First make sure the nodes are fresh and have not yet been initialized:

```
@ mediator1.health.initialized()
res1: Boolean = false
```

```
@ sequencer1.health.initialized()
res2: Boolean = false
```

```
@ domainManager1.health.initialized()
res3: Boolean = false
```

If the sync domain manager has `auto-init = true` (the default value) you need to make sure that the identity is generated and ready before you can bootstrap the sync domain:

```
@ domainManager1.health.wait_for_identity()
```

Note: This is technically only required when accessing the sync domain manager through a remote console, but is a good practice regardless.

If the sync domain manager has `auto-init = false`, then you need to manually initialize it by generating its identity and setting-up its keys:

```
// create namespace key for the domain manager
val namespaceKey = if (useKms) {
    mydomain_manager.keys.secret.register_kms_signing_key(
        namespaceKmsKeyIdDomainManager,
        name = mydomain_manager.name + "-namespace",
    )
} else {
    mydomain_manager.keys.secret
        .generate_signing_key(name = mydomain_manager.name + "-namespace")
}

// use the fingerprint of namespace key for our identity
val namespace = namespaceKey.fingerprint

// initialise the identity of this domain
val uid =
    mydomain_manager.topology.init_id(identifier = mydomain_manager.name,
    ↪ fingerprint = namespace)

// create the root certificate for this namespace
mydomain_manager.topology.namespace_delegations.authorize(
    ops = TopologyChangeOp.Add,
    namespace = namespace,
    authorizedKey = namespace,
    isRootDelegation = true,
```

(continues on next page)

(continued from previous page)

```

)

val protocolVersion = mydomain_manager.config.init.domainParameters.
    ↪initialProtocolVersion

// set the initial dynamic domain parameters for the domain
mydomain_manager.topology.domain_parameters_changes
    .authorize(
        domainId = DomainId(uid),
        newParameters = com.digitalasset.canton.admin.api.client.data.
    ↪DynamicDomainParameters
            .defaultValues(protocolVersion),
        protocolVersion = protocolVersion,
    )

// create signing key for the domain manager
val signingKeyDomainManager =
    if (useKms)
        mydomain_manager.keys.secret.register_kms_signing_key(
            signingKmsKeyIdDomainManager,
            name = mydomain_manager.name + "-signing",
        )
    else
        mydomain_manager.keys.secret
            .generate_signing_key(name = mydomain_manager.name + "-signing")

// create a topology transaction linking the domain manager to its signing key
mydomain_manager.topology.owner_to_key_mappings.authorize(
    ops = TopologyChangeOp.Add,
    keyOwner = DomainTopologyManagerId(uid),
    key = signingKeyDomainManager.fingerprint,
    purpose = KeyPurpose.Signing,
)

```

If you want, before continuing, you can pre-generate signing keys for mediators and sequencers by running:

```

mediator1.keys.secret.generate_signing_key(name = mediator1.name + "-signing")
sequencer1.keys.secret.generate_signing_key(name = sequencer1.name + "-signing")

```

Now you can initialize the distributed sync domain as follows:

```
@ domainManager1.setup.bootstrap_domain(Seq(sequencer1), Seq(mediator1))
```

At this point a participant should be able to connect to a sequencer and operate on that sync domain:

```
@ participant1.domains.connect_local(sequencer1)
```

```

@ participant1.health.ping(participant1)
res7: Duration = 413 milliseconds

```

Sync domain managers are configured as domain-managers under the `canton` configuration. Sync domain managers are configured similarly to sync domain nodes, except that there are no sequencer, mediator, public API, or service agreement configs.

Please note that if your sequencer is database-based and you're horizontally scaling it as described

in [sequencer high availability](#), you do not need to pass all sequencer nodes into the command above. Since they all share the same relational database, you only need to run this initialization step on one of them.

For a non-database-based sequencer such as Ethereum or Fabric sequencers you need to have each node initialized individually. You can either initialize such sequencers as part of the initial sync domain bootstrap shown above or dynamically add a new sequencer at a later point as described in [operational processes](#).

34.2.4 Set Up a Distributed Synchronization Domain With Separate Consoles

The process outlined in the previous section only works if all nodes are accessible from the same console environment. If each node has its own isolated console environment, the bootstrapping process must be coordinated in steps with the exchange of data via files using any secure channel of communication between the environments.

Note: Please ensure that all of the nodes in the distributed sync domain are started before proceeding. If you are running the domain manager with `auto-init = false`, then you need to manually generate its identity using the commands [listed in the previous section](#).

Initially the sync domain manager must transmit its sync domain parameters from its console by saving the parameters to a file. The sync domain ID, serialized as a string, must also be transmitted.

```
@ domainManager1.service.get_static_domain_parameters.writeToFile("tmp/domain-  
↳bootstrapping-files/params.proto")
```

```
@ val domainIdString = domainManager1.id.toProtoPrimitive  
domainIdString : String =  
↳"domainManager1::122070826d75201d2073af92380687e82a2632c7a40260843f37dda1bc1a7c298940  
↳"
```

Then the sequencer must receive this file, deserialize it and initialize itself. As part of the initialization, the sequencer creates a signing key pair whose public key it must then transmit via file. Optionally, repeat this for any extra sequencer nodes.

```
@ val domainParameters = com.digitalasset.canton.admin.api.client.data.  
↳StaticDomainParameters.tryReadFromFile("tmp/domain-bootstrapping-files/params.  
↳proto")  
domainParameters : StaticDomainParameters = StaticDomainParametersV1(  
  uniqueContractKeys = true,  
  requiredSigningKeySchemes = Set(Ed25519, ECDSA-P256, ECDSA-P384),  
  requiredEncryptionKeySchemes = Set(ECIES-P256_HMAC256_AES128-GCM),  
  requiredSymmetricKeySchemes = Set(AES128-GCM),  
  requiredHashAlgorithms = Set(Sha256),  
  requiredCryptoKeyFormats = Set(Tink, Raw, DER),  
  protocolVersion = 5  
)
```

```
@ val domainId = DomainId.tryFromString(domainIdString)  
domainId : DomainId = domainManager1::122070826d75...
```

```
@ sequencer1.keys.secret.generate_signing_key(sequencer1.name + "-signing")
res5: SigningPublicKey = SigningPublicKey(id = 1220988927ac..., format = Tink,
↳scheme = Ed25519)
```

```
@ val initResponse = sequencer1.initialization.initialize_from_beginning(domainId,
↳ domainParameters)
initResponse : com.digitalasset.canton.domain.sequencing.admin.grpc.
↳InitializeSequencerResponse = InitializeSequencerResponse(
  keyId = "sequencer-id",
  publicKey = SigningPublicKey(id = 1220988927ac..., format = Tink, scheme =
↳Ed25519),
  replicated = false
)
```

```
@ initResponse.publicKey.writeToFile("tmp/domain-bootstrapping-files/seq1-key.
↳proto")
```

The sync domain manager must then authorize the sequencer's key. Optionally, repeat this for any extra sequencer keys.

```
@ val sequencerPublicKey = SigningPublicKey.tryReadFromFile("tmp/domain-
↳bootstrapping-files/seq1-key.proto")
sequencerPublicKey : SigningPublicKey = SigningPublicKey(id = 1220988927ac...,
↳format = Tink, scheme = Ed25519)
```

```
@ domainManager1.setup.helper.authorizeKey(sequencerPublicKey, "sequencer",
↳SequencerId(domainManager1.id))
```

Now the mediator also needs to create a signing key pair and transmit it. Optionally, repeat this for any extra mediator nodes.

```
@ mediator1.keys.secret.generate_signing_key(mediator1.name + "-signing").
↳writeToFile("tmp/domain-bootstrapping-files/med1-key.proto")
```

The sync domain manager must now authorize the mediator's key and also authorize the mediator to act as part of this sync domain. Optionally, repeat this for any extra mediator nodes.

```
@ val mediatorKey = SigningPublicKey.tryReadFromFile("tmp/domain-bootstrapping-
↳files/med1-key.proto")
mediatorKey : SigningPublicKey = SigningPublicKey(id = 12201c4b751d..., format =
↳Tink, scheme = Ed25519)
```

```
@ val domainId = DomainId.tryFromString(domainIdString)
domainId : DomainId = domainManager1::122070826d75...
```

```
@ domainManager1.setup.helper.authorizeKey(mediatorKey, "mediator1",
↳MediatorId(domainId))
```

```
@ domainManager1.topology.mediator_domain_states.authorize(TopologyChangeOp.Add,
↳domainId, MediatorId(domainId), RequestSide.Both)
res14: com.google.protobuf.ByteString = <ByteString@6f32b7af size=560 contents="\
↳n\255\004\n\333\001\n\326\001\n\323\001\022 BTB3YskdIb37IU64bn53HsqgRVN6kkduR...
↳">
```

After that, still on the sync domain manager's console, the sync domain manager must collect the list of topology transactions, which includes all the key authorizations and a few other things it needs to broadcast to all sync domain members. This is now saved to a file.

```
@ domainManager1.topology.all.list().collectOfTypes[TopologyChangeOp.Positive].  
  ↳writeToFile("tmp/domain-bootstrapping-files/topology-transactions.proto")
```

The sequencer then reads this set of initial topology transactions and sequences it as the first message to be sequenced in this sync domain. This will allow the sync domain members whose keys were authorized in previous steps to connect to this sequencer and operate with it. The sequencer will then transmit its connection info.

```
@ val initialTopology = com.digitalasset.canton.topology.store.  
  ↳StoredTopologyTransactions.tryReadFromFile("tmp/domain-bootstrapping-files/  
  ↳topology-transactions.proto").collectOfTypes[TopologyChangeOp.Positive]  
initialTopology : store.StoredTopologyTransactions[TopologyChangeOp.Positive] =  
  ↳Seq(  
    StoredTopologyTransaction(  
      sequenced = 2024-06-26T13:05:43.093326Z,  
      validFrom = 2024-06-26T13:05:43.093326Z,  
      op = Add,  
      mapping = NamespaceDelegation(  
        ..  
      )  
    )  
  )
```

```
@ sequencer1.initialization.bootstrap_topology(initialTopology)
```

```
@ SequencerConnections.single(sequencer1.sequencerConnection).writeToFile("tmp/  
  ↳domain-bootstrapping-files/sequencer-connection.proto")
```

To initialize the mediator, it will need a connection to the sequencer and the sync domain parameters. Optionally, repeat this for any extra mediator nodes.

```
@ val sequencerConnections = SequencerConnections.tryReadFromFile("tmp/domain-  
  ↳bootstrapping-files/sequencer-connection.proto")  
sequencerConnections : SequencerConnections = Sequencer 'DefaultSequencer' ->  
  ↳GrpcSequencerConnection(  
    endpoints = http://127.0.0.1:30239,  
    transportSecurity = false  
  )
```

```
@ val domainParameters = com.digitalasset.canton.admin.api.client.data.  
  ↳StaticDomainParameters.tryReadFromFile("tmp/domain-bootstrapping-files/params.  
  ↳proto")  
domainParameters : StaticDomainParameters = StaticDomainParametersV1(  
  uniqueContractKeys = true,  
  requiredSigningKeySchemes = Set(Ed25519, ECDSA-P256, ECDSA-P384),  
  requiredEncryptionKeySchemes = Set(ECIES-P256_HMAC256_AES128-GCM),  
  requiredSymmetricKeySchemes = Set(AES128-GCM),  
  requiredHashAlgorithms = Set(Sha256),  
  requiredCryptoKeyFormats = Set(Tink, Raw, DER),  
  protocolVersion = 5  
)
```

```
@ mediator1.mediator.initialize(domainId, MediatorId(domainId), domainParameters,
↳sequencerConnections, None)
res21: PublicKey = SigningPublicKey(id = 12201c4b751d..., format = Tink, scheme =
↳Ed25519)
```

```
@ mediator1.health.wait_for_initialized()
```

The sync domain manager will also need a connection to the sequencer in order to complete its initialization.

```
@ val sequencerConnection = SequencerConnections.tryReadFromFile("tmp/domain-
↳bootstrapping-files/sequencer-connection.proto")
sequencerConnection : SequencerConnections = Sequencer 'DefaultSequencer' ->
↳GrpcSequencerConnection(
  endpoints = http://127.0.0.1:30239,
  transportSecurity = false
)
```

```
@ domainManager1.setup.init(sequencerConnection)
```

```
@ domainManager1.health.wait_for_initialized()
```

At this point the distributed sync domain should be completely initialized and a participant should be able to operate on this sync domain by connection to the sequencer.

```
@ participant1.domains.connect_local(sequencer1)
```

```
@ participant1.health.ping(participant1)
res27: Duration = 332 milliseconds
```

Additionally, please note that if more than one sequencer has been initialized, any mediator node and synchronizer manager can choose to connect to just a subset of them.

34.2.5 Add New Sequencers to a Distributed Synchronization Domain

For non-database-based sequencers such as Ethereum or Fabric sequencers, you can either initialize them as part of the regular [distributed sync domain bootstrapping process](#) or dynamically add a new sequencer at a later point as follows:

```
domainManager1.setup.onboard_new_sequencer(
  initialSequencer = sequencer1,
  newSequencer = sequencer2,
)
```

Similarly to [initializing a distributed sync domain with separate consoles](#), dynamically onboarding new sequencers (supported by Fabric and Ethereum sequencers) can be achieved in separate consoles as follows:

```
// Second sequencer's console: write signing key to file
{
  secondSequencer.keys.secret
    .generate_signing_key(s"${secondSequencer.name}-signing")
}
```

(continues on next page)

(continued from previous page)

```

        .writeToFile(file1)
    }

    // Domain manager's console: write domain params and current topology
    {
        domainManager1.service.get_static_domain_parameters.writeToFile(paramsFile)

        val sequencerSigningKey = SigningPublicKey.tryReadFromFile(file1)

        domainManager1.setup.helper.authorizeKey(
            sequencerSigningKey,
            s"${secondSequencer.name}-signing",
            sequencerId,
        )

        domainManager1.setup.helper.waitForKeyAuthorizationToBeSequenced(
            sequencerId,
            sequencerSigningKey,
        )

        domainManager1.topology.all
            .list(domainId.filterString)
            .collectOfTypes[TopologyChangeOp.Positive]
            .writeToFile(file1)
    }

    // Initial sequencer's console: read topology and write snapshot to file
    {
        val topologySnapshotPositive =
            StoredTopologyTransactions
                .tryReadFromFile(file1)
                .collectOfTypes[TopologyChangeOp.Positive]

        val sequencingTimestamp = topologySnapshotPositive.lastChangeTimestamp.
        ↪getOrNull(
            sys.error("topology snapshot is empty")
        )

        sequencer.sequencer.snapshot(sequencingTimestamp).writeToFile(file2)
    }

    // Second sequencer's console: read topology, snapshot and domain params
    {
        val topologySnapshotPositive =
            StoredTopologyTransactions
                .tryReadFromFile(file1)
                .collectOfTypes[TopologyChangeOp.Positive]

        val state = SequencerSnapshot.tryReadFromFileUnsafe(file2)

        val domainParameters = StaticDomainParameters.tryReadFromFile(paramsFile)

        secondSequencer.initialization
            .initialize_from_snapshot(
                domainId,
                topologySnapshotPositive,
            )
    }

```

(continues on next page)

(continued from previous page)

```

        state,
        domainParameters,
    )
    .publicKey

    secondSequencer.health.initialized() shouldBe true
}

```

A newly onboarded sequencer only serves events more recent than the onboarding snapshot. In addition some events may belong to transactions initiated before the sequencer was onboarded, but the sequencer is not in a position to sign such events and replaces them with tombstones. If a participant (or mediator) connects to a newly onboarded sequencer too soon and the subscription encounters a tombstone, the sequencer subscription aborts with a `FAILED_PRECONDITION` error specifying `InvalidCounter` or `SEQUENCER_TOMBSTONE_ENCOUNTERED`. If this occurs, the participant or mediator should connect to another sequencer with a longer history of sequenced events before switching to the newly onboarded sequencer. To avoid such errors the best practice is to wait at least for the `maximum decision duration` (the sum of the `participant_response_timeout` and `mediator_reaction_timeout` dynamic sync domain parameters with a default of 30 seconds each) before connecting nodes to a newly onboarded sequencer.

34.3 Manage Participants

34.3.1 Manual vs Automatic Identity Initialization

Similarly to a domain, a participant node can either be initialized automatically, the default behaviour, or manually. Managing the initialization manually is particularly useful when a participant:

1. Does not control its own identity;
2. When you do not want to store its identity key on the node for security reasons;
3. When you want to set a participant's keys by yourself.

If you want to disable the automatic initialization of a participant node you have to set:

```
participant.init.auto-init = false
```

34.3.2 Keys Initialization

Besides a namespace key and a signing key a participant node also has an asymmetric encryption key that it uses to decrypt encrypted transactions. Key are created automatically, however, if you are manually setting up your participant node you must use the following commands to generate your signing keys (for namespace and signing) and the encryption key:

```

/* Create or register three keys:
 * 1. a signing key that is going to control our identity;
 * 2. a signing key;
 * 3. an encryption key to encrypt transactions;
 */
val ((identityKey, signingKey), encryptionKey) = if (useKms) {
    // user-manual-entry-begin: ManualRegisterKmsKeys

```

(continues on next page)

(continued from previous page)

```

participant.keys.secret
    .register_kms_signing_key(namespaceKmsKeyId, name = participant.name + "-
↪namespace") ->
    participant.keys.secret
    .register_kms_signing_key(signingKmsKeyId, name = participant.name + "-
↪signing") ->
    participant.keys.secret
    .register_kms_encryption_key(encryptionKmsKeyId, name = participant.name +
↪"-encryption")
    // user-manual-entry-end: ManualRegisterKmsKeys
} else {
    participant.keys.secret.generate_signing_key(name = participant.name + "-
↪namespace") ->
    participant.keys.secret.generate_signing_key(name = participant.name + "-
↪signing") ->
    participant.keys.secret.generate_encryption_key(name = participant.name + "-
↪encryption")
}

```

If you are using a Key Management Service (KMS) to handle Canton's keys and you want to use a set of pre-generated keys you must use instead the commands `register_kms_signing_key()` and `register_kms_encryption_key()`

Please refer to [External Key Storage with a Key Management Service \(KMS\)](#) for more details.

34.3.3 Participant Manual Initialization

The following steps describe how to manually initialize a participant node after the keys have been generated:

```

// use the fingerprint of this key for our identity
val namespace = identityKey.fingerprint

// create the root certificate (self-signed)
participant.topology.namespace_delegations.authorize(
    ops = TopologyChangeOp.Add,
    namespace = namespace,
    authorizedKey = namespace,
    isRootDelegation = true,
)

// initialise the id: this needs to happen AFTER we created the namespace
↪delegation
// (on participants; for the domain, it's the other way around ... sorry for that)
// if we initialize the identity before we added the root certificate, then the
↪system will
// complain about not being able to vet the admin workflow packages automatically.
// that would not be tragic, but would require a manual vetting step.
// in production, use a "random" identifier. for testing and development, use
↪something
// helpful so you don't have to grep for hashes in your log files.
participant.topology.init_id(
    identifier = Identifier.tryCreate("manualInit"),
    fingerprint = namespace,

```

(continues on next page)

(continued from previous page)

```

)

// assign new keys to this participant
Seq(encryptionKey, signingKey).foreach { key =>
  participant.topology.owner_to_key_mappings.authorize(
    ops = TopologyChangeOp.Add,
    keyOwner = participant.id,
    key = key.fingerprint,
    purpose = key.purpose,
  )
}

```

34.4 Ledger Pruning

Pruning refers to the selective removal of old, stale, or unneeded data from participant, sync domain sequencer, and mediator nodes. Nodes operate continuously for an indefinite amount of time on a limited amount of storage. In addition, privacy demands may require removing Personally Identifiable Information (PII) upon request.

Pruning participant nodes means removing archived contracts (and associated transactions and events). Pruning never removes active (i.e., non-archived) Daml contracts. For sync domain sequencers and mediators, pruning relates to the removal of processed messages. Participants and sync domain sequencers and mediators can have different pruning schedules set.

34.4.1 Enable Automatic Pruning

Enable automatic pruning by specifying a pruning schedule consisting of the following:

- A cron expression that designates regular pruning begin times .
- A maximum duration specifying pruning end times relative to the begin times of the cron expression.
- A retention period to specify how far to prune relative to the current time.

For example, to run pruning every Saturday starting at 8 am until 4 pm (both in UTC):

```

participant.pruning.set_schedule("0 0 8 ? * SAT", 8.hours, 90.days)
domain.sequencer.pruning.set_schedule("0 0 8 ? * SAT", 8.hours, 90.days)
domain.mediator.set_schedule("0 0 8 ? * SAT", 8.hours, 90.days)

```

Refer to the cron specification to customize the pruning schedule. Here are a few examples:

```

set_schedule("0 0 20 * * ?", 2.hours, retention) // run every evening at 8pm GMT
↳for two hours
set_schedule("0 /5 * * * ?", 1.minute, retention) // run every 5 minutes for one
↳minute
set_schedule("0 0 0 31 12 ? 2023", 1.day, retention) // run for one specific day

```

For the maximum duration to specify a reliable pruning window end time , the leading fields of the cron expression should not be wildcards (*) as illustrated in the examples above. If the hour field is fixed, so should the fields for minute and second.

34.4.2 Schedule format

Cron expressions are formatted as 7 whitespace-separated fields:

Field	Type and valid values*
seconds	number from 0 to 59
minutes	number from 0 to 59
hours	number from 0 to 23
day of the month	number from 1 to 31
month	number from 0 to 11 (0 = January) or the first three letters of the month name (JAN, FEB, MAR,)
day of the week	number from 1 to 7 (1 = Sunday) or the first three letters of the day name (SUN, MON, TUE,)
year (optional)	number from 1900 to 2099

*Ranges specified with `to` are inclusive of both endpoints.

Note that although a day-of-the-month value might be valid according to the above definition, it might not correspond to an actual date in certain months (such as the 31st of November). If you schedule pruning for the 31st of the month, every month with fewer than 31 days will be skipped.

34.4.2.1 Advanced schedule formatting

You can construct **lists and ranges** of values. For example, the day of the week could be a range like `MON-FRI` to refer to the days Monday through Friday, or `TUE, FRI` to refer to Tuesday and Friday exclusively. Or you could use a mix of both, for example, `MON, WED-FRI`, meaning Monday, and also Wednesday through Friday.

Use the **asterisk** (*) as a wildcard that means all possible values.

Use the **question mark** (?) as a wildcard that means any value in the day-of-the-month and day-of-the-week fields. For example, to specify every Monday at noon, use the ? character to indicate that any day of the month is valid: `0 0 12 ? * MON`

To apply **increments** to numeric values, use the slash character (/). For example, a value of `1/2` in the hours field means every two hours starting from 1 AM (1 AM, 3 AM, 5 AM,).

Here are some examples of valid schedules:

`0 30 * * * *` — Every hour at half past

`0 5/15 12,18-20 * * *` — Every fifteen minutes, starting from five past, at noon and from 6 to 8 PM

`0 5/15 12,18-20 ? * MON, THU` — Same as above, but only on Monday and Thursday

`0 0 22 1 * ?` — Every first day of the month at 10 PM

For more information about cron expressions, see the [Apache Log4j API documentation](#).

34.4.3 Monitor Pruning Progress

Monitor the pruning state to determine that the pruning schedule allows participant, mediator, and sequencer pruning to keep up with ledger growth, and is not stuck for one of the reasons described below in the [Common Notes](#).

Specifically, monitor the *max-event-age* metrics describing the age of the oldest, un-pruned event (in hours):

```
<participant>.prune.max-event-age
<mediator>.max-event-age
<sequencer>.max-event-age
```

The *max-event-age* metrics should not exceed the value of the pruning schedule *retention* plus the length of the interval. For example, if your schedule specifies a retention of 30 days and a cron that calls for weekly pruning, *max-event-age* must remain below 37 days. If for any node the *max-event-age* metric exceeds this upper limit, you should consider allocating more time for pruning by reducing the interval between pruning windows or by increasing the *maximum duration* pruning schedule setting.

34.4.4 Best Practices

Pruning deletes data from the database, freeing up space, but it does not perform any database maintenance such as table resizing. PostgreSQL supports automatic and manual vacuuming for this purpose, but Oracle lacks such support and relies on the database administrator to manage freed database space.

Pruning is an IO-heavy operation and would have an impact on overall system performance (lowering throughput during pruning by as much as 50% in our test environments), hence it is preferable to schedule pruning during maintenance windows such as after taking database backups or during low load.

A catastrophic failure of a participant and its backup can be mitigated by rebuilding its state from the sequencer by replaying messages. However, this becomes impossible once the required messages have been pruned from the sequencer. For this reason, the backup strategy for participant nodes should be coordinated with the sequencer's pruning schedule.

For high-availability nodes that share a common database, the pruning schedule has to be set on the active participant replica, the active mediator replica, or the admin sequencer. The `sequencer.health.status` command helps identify the sequencer that accepts admin changes such as configuring pruning when `sequencer.health.status.trySuccess.admin.exists(_.acceptsAdminChanges)` is `true`.

Participants, mediators, and sequencers also expose manual *prune** methods that come with pitfalls. The methods might appear to be hanging unless the range of events and messages specified for pruning is not broken up into sufficiently small chunks. In addition, these manual methods have no built-in mechanism to resume on another node after a high-availability failover. Automatic pruning is recommended instead.

34.4.5 Current Limitations

The sequencer will only allow pruning of acknowledged events. As such, if a client such as a participant or mediator stops acknowledging events that have been sent to it, sequencer pruning will be blocked. This is a current limitation.

Generally, idle sequencer clients will only acknowledge once they have observed subsequent events. This means that idle clients normally won't acknowledge the last event. Since each member requests a time-proof once per day, there is a default limitation that a system with idle but connected clients cannot be pruned with a retention window of less than 24 hours. As the topology manager connects to the sequencer but is often idle and only invoked on topology changes, this limitation manifests itself when pruning test environments where aggressive pruning windows of less than 24 hours are used. This can be fixed by adjusting the sync domain-tracker time of the topology manager: `canton.domains.mydomain.time-tracker.min-observation-duration = 1h`.

Pruning of participants requires the participant to have received a commitment from each counter-participant with which it shares a contract. If a participant becomes defunct and stops sending commitments, pruning of the participant will not work. Therefore, before you disable a participant, please make sure that is not involved in any contract. This is a current limitation. Participants do not allow pruning of state more recent than the most recently observed transaction minus the `ledger-api.max-deduplication-duration` configuration. As a result, an inactive participant may not prune all archived contracts and transactions older than the configured retention period.

Refer to the Participant Pruning section to learn how pruning affects Daml applications and the Ledger API.

34.5 Participant Pruning

The Daml Ledger API exposes an append-only ledger model; on the other hand, Daml Participants must be able to operate continuously for an indefinite amount of time on a limited amount of hot storage.

In addition, privacy demands¹ may require removing Personally Identifiable Information (PII) upon request.

To satisfy these requirements, the [Pruning Service](#) Ledger API endpoint² allows Daml Participants to support pruning of Daml contracts and transactions that were respectively archived and submitted before or at a given ledger offset.

Please refer to the specific Daml driver information for details about its pruning support.

¹ For example, as enabled by provisions about the right to be forgotten of legislation such as [EU's GDPR](#).

² Invoking the Pruning Service requires administrative privileges.

34.5.1 Impacts on Daml Applications

When supported, pruning can be invoked by an operator with administrative privileges at any time on a healthy Daml participant; furthermore, it doesn't require stopping nor suspending normal operation.

Still, Daml applications may be affected in the following ways:

Pruning is potentially a long-running operation and demanding one in terms of system resources; as such, it may significantly reduce Daml Ledger API throughput and increase latency while it is being performed. It is thus strongly recommended to plan pruning invocations, preferably, when the system is offline or at least when very low system utilization is expected. Pruning may degrade the behavior of or abort in-progress requests if the pruning offset is too recent. In particular, the system might misbehave if command completions are pruned before the command trackers are able to process the completions.

Command deduplication and command tracker retention should always be configured so that the associated windows don't overlap with the pruning window to ensure that their operation is unaffected by pruning.

Pruning may affect the behavior of Ledger API calls that allow to read data from the ledger: see the next sub-section for more information about API impacts.

Pruning of all divulged contracts (see [Prune Request](#)) does not preserve application visibility over contracts divulged up to the pruning offset, hence applications making use of pruned divulged contracts might start experiencing failed command submissions: see the section below for determining a suitable pruning offset.

Warning: Participants may know of contracts for which they don't know the current activeness status. This happens through [divulgence](#) where a party learns of the existence of a contract without being guaranteed to ever see its archival. Such contracts are pruned by the feature described on this page as not doing so could easily lead to an ever growing participant state.

During command submission, parties can fetch divulged contracts. This is incompatible with the pruning behaviour described above which allows participant operators to reclaim storage space by pruning divulged contracts. Daml code running on pruned participants should therefore never rely on existence of divulged contracts prior to or at the pruning offset. Instead, such applications **MUST** ensure re-divulgence of the used contracts.

34.5.2 How the Daml Ledger API is Affected

Pruning of old data is not noticed by applications that are up to date. However pruning data in active use by applications can result in the following errors:

Active data streams from the Daml Participant may abort and need to be re-established by the Daml application from a later offset than pruned, even if they are already streaming past it.

Requesting information at offsets that predate pruning, including from the ledger's start, will result in a `FAILED_PRECONDITION` gRPC error. - As a consequence, after pruning, a Daml application must bootstrap from the Active Contract Service and a recent offset³.

Submission validation and Daml Ledger API endpoints that write to the ledger are generally not affected by pruning; an exception is that in-progress calls could abort while awaiting completion.

³ This might be improved in future versions.

Please refer to the [protobuf documentation of the API](#) for details about the `prune` operation itself and the behavior of other Daml Ledger API endpoints when pruning is being or has been performed.

34.5.3 Other Limitations

Pruning may be rejected even if the node is running correctly (for example, to preserve non-repudiation properties); in this case, the application might not be able to archive contracts containing PII or pruning of these contracts may not be possible; thus, actually deleting this PII may also be technically unfeasible.

Pruning may leave parties, packages, and configuration data on the participant node, even if they are no longer needed for transaction processing, and even if they contain PII [Page 1611, 3](#).

Pruning does not move pruned information to cold storage but simply deletes pruned data; for this reason, it is advisable to back up the Participant Index DB before invoking pruning. See the next sub-section for more Participant Index DB-related advice before and after invoking `prune`. Pruning is not selective but rather effectively truncates the ledger, removing events on behalf of archived contracts and command completions at the pruning offset and all previous offsets.

34.5.4 How Pruning Affects Index DB Administration

Pruning deletes data from the participant's database and therefore frees up space within it, which can and will be reused during the continued operation of the Index DB. Whether this freed up space is handed back to the OS depends on the database in use. For example, in PostgreSQL the deleted data frees up space in the table storage itself, but does not shrink the size of the files backing the tables of the IndexDB. Please refer to the PostgreSQL documentation on `VACUUM` and `VACUUM FULL` for more information.

Activities to be carried out *before* invoking a pruning operation should thus include backing up the Participant Index DB, as pruning will not move information to cold storage but rather it will delete events on behalf of archived contracts and command completions before or at the pruning offset.

In addition, activities to be carried out *after* invoking a pruning operation might include:

On a PostgreSQL Index DB, especially if auto-vacuum tuning has not been performed, issuing `VACUUM` commands at appropriate times may improve performance and storage usage by letting the database reuse freed space. Note that `VACUUM FULL` commands are still needed for the OS to reclaim disk space previously used by the database.

Backing up and vacuuming, in addition to pruning itself, are also long-running and resource-hungry operations that might negatively affect the performance of regular workloads and even the availability of the system: this is true in particular for `VACUUM FULL` in PostgreSQL and equivalent commands in other DBMSs. These operations should thus be planned and taken carefully into account when sizing system resources. They should also be scheduled sensibly in relation to the desired sustained performance levels of regular workloads and to the hot storage usage goals.

Professional advice on database administration is strongly recommended that would take into account the DB specifics as well as all of the above aspects.

34.5.5 Determine a Suitable Pruning Offset

The [Transaction Service](#) and the [Active Contract Service](#) provide offsets of the ledger end of the Transactions, and of Active Contracts snapshots respectively. Such offsets can be passed unchanged to `prune` calls, as long as they are lexicographically lower than the current ledger end. An additional constraint imposed by Canton is that the participant you are pruning must have already exchanged the ACS commitments with other participants for the offset that you prune at. Refer to [Canton pruning documentation](#) for more information.

When pruning all divulged contracts, the participant operator can choose the pruning offset (provided that the suitable ACS commitments have already been exchanged) as follows:

Just before the ledger end, if no application hosted on the participant makes use of divulgence
OR

An offset old enough (e.g. older than an arbitrary multi-day grace period) that it ensures that pruning does not affect any recently-divulged contract needed by the applications hosted on the participant.

Scheduled jobs, applications and/or operator tools can be built on top of the Daml Ledger API to implement pruning automatically, for example at regular intervals, or on-demand, for example according to a user-initiated process.

For instance, pruning at regular intervals could be performed by a cron job that:

1. If a pruning interval has been saved to a well-known location:
 - a. Backs up the Daml Participant Index DB.
 - b. Performs pruning.
 - c. (If using PostgreSQL) Performs a `VACUUM FULL` command on the Daml Participant Index DB.
2. Queries the current ledger end and saves its offset.

The interval between 2 (i.e. saving a recent ledger end offset) and the next cron job run determines the data retention window, that should be long enough not to affect deduplication and commands completion. For example, pruning at a recent ledger end offset could be problematic and should be avoided.

Pruning could also be initiated on-demand at the offset of a specific transaction⁴, for example as provided by a user application based on search.

34.6 Participant Metering

Participant metering is a way to report how many events have been submitted in a given period of time.

Daml command execution results in a Daml transaction that contains events associated with the processing of the command.

The events included in the report include:

- Contract creation
- Exercise of a contract (including non-consuming exercises and exercise by key)
- Fetch of a contract (including fetch by key)
- Lookup by contract key

⁴ Note that all the events on behalf of archived contracts and command completions found at earlier offsets will also be pruned.

Only events that originated from the local participant are included in the metering. Events received by the local participant from remote participants are *not* included.

Only events contained in committed transactions are included, a failed transaction has no effect on ledger metering.

34.6.1 Generate a Metering Report

A metering report is generated using the [Daml assistant](#) utility.

To run a metering report `daml ledger metering-report` is used with the following metering specific arguments:

- `--from` A start date that is used to initiate the reporting period. Events on or after this date will be included.
- `--to` An end date that may be used to terminate the reporting period. Events prior to this date will be included. If an end date is not provided then the report will contain counts of all events that occurred on or after the `--from` date.
- `--application` Optionally, provide an application to limit the report to that application.

The from and to dates above should be formatted `yyyy-mm-dd`. The exact timestamp used for the report will be the start of the UTC day provided.

Ledger metering is not affected by participant pruning.

Other non-metering specific Daml assistant flags may also be used alongside those shown above.

34.6.2 Example

To report on all applications for January 2022 the following from/to flags would be set:

```
daml ledger metering-report --from 2022-01-01 --to 2022-02-01
```

34.6.3 Output

```
{
  "participant": "some-participant",
  "request": {
    "from": "2022-01-01T00:00:00Z",
    "to": "2022-02-01T00:00:00Z"
  },
  "final": true,
  "applications": [
    {
      "application": "some-application",
      "events": 42
    }
  ],
  "check": {
    "digest": "sxRZw40JJ5gWGUJoecm6-i-UPQ2imBVqeOYnbmYhVNA=",
    "scheme": "canton-enterprise-2022"
  }
}
```

The output consists of the following sections:

- participant** The name of the local participant the report applies to
- request** This section gives details of the parameters that were used to generate the report
- final** This field will be set to `true` if a `--to` date was provided and the `--to` date is in the past. Once a report is marked as final the event counts will never change and so may be used for billing purposes.
- applications** This section will give an event count for each application used in the reporting period.
- check** This section is used by the billing operator to verify that the report has not been modified.

34.7 API Configuration

A sync domain exposes two main APIs, the admin API and the public API, while the participant node exposes the ledger API and the admin API. In this section, we will explain what the APIs do and how they can be configured.

34.7.1 Default Ports

Canton assigns ports automatically for all the APIs of all the configured nodes if the port has not been configured explicitly. The ports are allocated according to the following scheme:

```
/** Participant node default ports */
val ledgerApiPort = defaultPortStart(4001)
val participantAdminApiPort = defaultPortStart(4002)

/** Domain node default ports */
val domainPublicApiPort = defaultPortStart(4201)
val domainAdminApiPort = defaultPortStart(4202)

/** External sequencer node default ports (enterprise-only) */
val sequencerPublicApiPort = defaultPortStart(4401)
val sequencerAdminApiPort = defaultPortStart(4402)

/** External mediator node default port (enterprise-only) */
val mediatorAdminApiPort = defaultPortStart(4602)

/** Domain node default ports */
val domainManagerAdminApiPort = defaultPortStart(4801)

/** External sequencer node x default ports (enterprise-only) */
val sequencerXPublicApiPort = defaultPortStart(5001)
val sequencerXAdminApiPort = defaultPortStart(5002)

/** External mediator node x default port (enterprise-only) */
val mediatorXAdminApiPort = defaultPortStart(5202)

/** Increase the default port number for each new instance by portStep */
private val portStep = 10
```

34.7.2 Administration API

The nature and scope of the admin API on participant nodes and the admin API on sync domains has some overlap. As an example, you will find the same key management commands on the sync domain and the participant node API, whereas the participant has different commands to connect to several sync domains.

The configuration currently is simple (see the TLS example below) and just takes an address and a port. The address defaults to 127.0.0.1 and a default port is assigned if not explicitly configured.

You should not expose the admin-api publicly in an unsecured way as it serves administrative purposes only.

34.7.3 TLS Configuration

Both the Ledger API and the admin API provide the same TLS capabilities and can be configured using the same configuration directives. TLS provides end-to-end channel encryption between the server and client, and depending on the settings, server or mutual authentication.

A full configuration example is given by

```
canton.participants.participant4.ledger-api {
  address = "127.0.0.1" // IP / DNS must be SAN of certificate to allow local
  ↪connections from the canton process
  port = 5041
  tls {
    // the certificate to be used by the server
    cert-chain-file = "./tls/ledger-api.crt"
    // private key of the server
    private-key-file = "./tls/ledger-api.pem"
    // trust collection, which means that all client certificates will be
  ↪verified using the trusted
    // certificates in this store. if omitted, the JVM default trust store is
  ↪used.
    trust-collection-file = "./tls/root-ca.crt"
    // define whether clients need to authenticate as well (default not)
    client-auth = {
      // none, optional and require are supported
      type = require
      // If clients are required to authenticate as well, we need to provide a
  ↪client
      // certificate and the key, as Canton has internal processes that need to
  ↪connect to these
      // APIs. If the server certificate is trusted by the trust-collection, then
  ↪you can
      // just use the server certificates. Otherwise, you need to create separate
  ↪ones.
      admin-client {
        cert-chain-file = "./tls/admin-client.crt"
        private-key-file = "./tls/admin-client.pem"
      }
    }
    // minimum-server-protocol-version = ...
    // ciphers = ...
  }
}
```

(continues on next page)

(continued from previous page)

}

These TLS settings allow a connecting client to ensure that it is talking to the right server. In this example, we have also enabled client authentication, which means that the client needs to present a valid certificate (and have the corresponding private key). The certificate is valid if it has been signed by a key in the trust store.

The `trust-collection-file` allows us to provide a file-based trust store. If omitted, the system will default to the built-in JVM trust store. The file must contain all client certificates (or parent certificates that were used to sign the client certificate) who are trusted to use the API. The format is just a collection of PEM certificates (in the right order or hierarchy), not a Java-based trust store.

If you want to use mTLS on the admin API, you must sign the client certificates with the certificate defined in the `trust-collection-file`.

In order to operate the server just with server-side authentication, you can just omit the section on `client-auth`. However, if `client-auth` is set to `require`, then Canton also requires a client certificate, as various Canton internal processes will connect to the process itself through the API.

All the private keys need to be in the `pkcs8` PEM format.

By default, Canton only uses new versions of TLS and strong ciphers. You can also override the default settings using the variables `ciphers` and `protocols`. If you set these settings to `null`, the default JVM values will be used.

Note: Error messages on TLS issues provided by the networking library `netty` are less than optimal. If you are struggling with setting up TLS, please enable `DEBUG` logging on the `io.netty` logger.

Note that the configuration hierarchy for a [remote participant console](#) is slightly different from the in-process console or participant shown above.

If you need to create a set of testing TLS certificates, you can use the following `openssl` commands:

```
# include certs-common.sh from config/tls
. "$(dirname "${BASH_SOURCE[0]}")/certs-common.sh"

# create root certificate such that we can issue self-signed certs
create_key "root-ca"
create_certificate "root-ca" "/O=TESTING/OU=ROOT CA/
↪emailAddress=canton@digitalasset.com"
#print_certificate "root-ca"

# create public api certificate
create_key "public-api"
create_csr "public-api" "/O=TESTING/OU=DOMAIN/CN=localhost/
↪emailAddress=canton@digitalasset.com" "DNS:localhost,IP:127.0.0.1"
sign_csr "public-api" "root-ca"
print_certificate "public-api"

# create participant ledger-api certificate
create_key "ledger-api"
create_csr "ledger-api" "/O=TESTING/OU=PARTICIPANT/CN=localhost/
↪emailAddress=canton@digitalasset.com" "DNS:localhost,IP:127.0.0.1"
```

(continues on next page)

(continued from previous page)

```

sign_csr "ledger-api" "root-ca"

# create participant admin-api certificate
create_key "admin-api"
create_csr "admin-api" "/O=TESTING/OU=PARTICIPANT ADMIN/CN=localhost/
↪emailAddress=canton@digitalasset.com" "DNS:localhost,IP:127.0.0.1"
sign_csr "admin-api" "root-ca"

# create participant client key and certificate
create_key "admin-client"
create_csr "admin-client" "/O=TESTING/OU=PARTICIPANT ADMIN CLIENT/CN=localhost/
↪emailAddress=canton@digitalasset.com"
sign_csr "admin-client" "root-ca"
print_certificate "admin-client"

```

If you are having problems with SSL connectivity, you can enable SSL debugging by adding the following flag to the command line when starting Canton:

```
bin/canton -Djavax.net.debug=all
```

This will enable detailed SSL debugging information to be printed to the console, which can help you diagnose and troubleshoot any problems you may be experiencing. It is recommended to only enable this flag when needed, as the output can be very verbose and may impact the performance of your application.

34.7.4 Keep Alive

In order to prevent load-balancers or firewalls from terminating long-running RPC calls in the event of some silence on the connection, all GRPC connections enable keep-alive by default. An example configuration for an adjusted setting is given below:

```

canton.participants.participant2 {
  admin-api {
    address = "127.0.0.1"
    port = 5022
    keep-alive-server {
      time = 40s
      timeout = 20s
      permit-keep-alive-time = 20s
    }
  }
  sequencer-client {
    keep-alive-client {
      time = 60s
      timeout = 30s
    }
  }
}

```

GRPC client connections are configured with `keep-alive-client`, with two settings: `time`, and `timeout`. The effect of the `time` and `timeout` settings are described in the [GRPC documentation](#).

Servers can also change two other settings: `permit-keep-alive-time` and `permit-keep-alive-without-calls`. The value in `permit-keep-alive-time` speci-

fies the most aggressive keep-alive time that a client is permitted to use. If a client uses keep-alive time that is more aggressive than the `permit-keep-alive-time`, the connection is terminated with a GOAWAY frame with `too_many_pings` as the debug data. Setting `permit-keep-alive-without-calls` to true allows clients to send ping messages outside of any ongoing GRPC call. Such a ping otherwise results in a GOAWAY frame.

The default values of these parameters are set differently for different APIs:

API	Admin API	Public API	Ledger API
time	40s	40s	10min
timeout	20s	20s	20s
permit-keep-alive-time	20s	20s	10s
permit-keep-alive-without-calls	false	false	true

These settings are described in more detail in the [GRPC documentation](#) and [GRPC manual page](#).

34.7.5 Max Inbound Message Size

The APIs exposed by both the participant (ledger API and admin API) as well as by the sync domain (public API and admin API) have an upper limit on incoming message size. To increase this limit to accommodate larger payloads, the flag `max-inbound-message-size` has to be set for the respective API to the maximum message size in **bytes**.

For example, to configure a participant's ledger API limit to 20MB:

```
canton.participants.participant2.ledger-api {
  address = "127.0.0.1"
  port = 5021
  max-inbound-message-size = 20971520
}
```

34.7.6 Participant Configuration

34.7.6.1 Ledger Api

The configuration of the ledger API is similar to the admin API configuration, except that the group starts with `ledger-api` instead of `admin-api`.

JWT Authorization

The Ledger Api supports [JWT](#) based authorization checks as described in the [Authorization documentation](#).

In order to enable JWT authorization checks, your safe configuration options are

```
_shared {
  ledger-api {
    auth-services = [{
      // type can be
      //   jwt-rs-256-crt
```

(continues on next page)

(continued from previous page)

```

    //  jwt-es-256-crt
    //  jwt-es-512-crt
    type = jwt-rs-256-crt
    // we need a certificate file (abcd.cert)
    certificate = ${JWT_CERTIFICATE_FILE}
  ]]
}
}

```

jwt-rs-256-crt. The participant will expect all tokens to be signed with RS256 (RSA Signature with SHA-256) with the public key loaded from the given X.509 certificate file. Both PEM-encoded certificates (text files starting with -----BEGIN CERTIFICATE-----) and DER-encoded certificates (binary files) are supported.

jwt-es-256-crt. The participant will expect all tokens to be signed with ES256 (ECDSA using P-256 and SHA-256) with the public key loaded from the given X.509 certificate file. Both PEM-encoded certificates (text files starting with -----BEGIN CERTIFICATE-----) and DER-encoded certificates (binary files) are supported.

jwt-es-512-crt. The participant will expect all tokens to be signed with ES512 (ECDSA using P-521 and SHA-512) with the public key loaded from the given X.509 certificate file. Both PEM-encoded certificates (text files starting with -----BEGIN CERTIFICATE-----) and DER-encoded certificates (binary files) are supported.

Instead of specifying the path to a certificate, you can also a [JWKS](#) URL. In that case, the participant will expect all tokens to be signed with RS256 (RSA Signature with SHA-256) with the public key loaded from the given JWKS URL.

```

_shared {
  ledger-api {
    auth-services = [{
      type = jwt-rs-256-jwks
      // we need a URL to a jwks key, e.g. https://path.to/jwks.key
      url = ${JWT_URL}
    }]
  }
}

```

Warning: For testing purposes only, you can also specify a shared secret. In that case, the participant will expect all tokens to be signed with HMAC256 with the given plaintext secret. This is not considered safe for production.

```

_shared {
  ledger-api {
    auth-services = [{
      type = unsafe-jwt-hmac-256
      secret = "not-safe-for-production"
    }]
  }
}

```

Note: To prevent man-in-the-middle attacks, it is highly recommended to use TLS with server au-

thentication as described in [TLS Configuration](#) for any request sent to the Ledger API in production.

Note that you can define multiple authorization plugins. If more than one is defined, the system will use the claim of the first auth plugin that does not return Unauthorized.

If no authorization plugins are defined, a default (wildcard) authorization method is used.

Leeway Parameters for JWT Authorization

You can define leeway parameters for authorization using JWT tokens. An authorization that fails due to clock skew between the signing and the verification of the tokens can be eased by specifying a leeway window in which the token should still be considered valid. Leeway can be defined either specifically for the **Expiration Time (exp)**, **Not Before (nbf)** and **Issued At (iat)** claims of the token or by a default value for all three. The values defining the leeway for each of the three specific fields override the default value if present. The leeway parameters should be given in seconds and can be defined as in the example configuration below:

```
canton.participants.participant.parameters.ledger-api-server-parameters.jwt-
timestamp-leeway {
  default = 5
  expires-at = 10
  issued-at = 15
  not-before = 20
}
```

Configuring the Target Audience for JWT Authorization

The default audience (aud field in the audience-based token) for authenticating on the Ledger Api using JWT is `https://daml.com/participant/jwt/aud/participant/${participantId}`. Other audiences can be configured explicitly using the custom target audience configuration option:

```
canton {
  participants {
    participant {
      ledger-api {
        auth-services = [{
          type = jwt-rs-256-jwks
          url = "https://target.audience.url/jwks.json"
          target-audience = "https://rewrite.target.audience.url"
        }]
      }
    }
  }
}
```

Configuring the Target Scope for JWT Authorization

The default scope (scope field in the scope-based access token) for authenticating on the Ledger API using JWT is `daml_ledger_api`.

Other scopes can be configured explicitly using the custom target scope configuration option:

```
canton {
  participants {
    participant {
      ledger-api {
        auth-services = [{
          type = jwt-rs-256-jwks
          url = "https://some.url/jwks.json"
          target-scope = "custom/Scope-5:with_special_characters"
        }]
      }
    }
  }
}
```

Target scope can be any case-sensitive string containing alphanumeric characters, hyphens, slashes, colons and underscores. Either the `target-scope` or the `target-audience` parameter can be configured individually, but not both at the same time.

Ledger API Caches

The `max-contract-state-cache-size` and `max-contract-key-state-cache-size` parameters control the sizes of the ledger API contract and contract key caches, respectively. Modifying these parameters changes the likelihood that a transaction using a contract or a contract key that was recently accessed (created or read) can still find it in the memory, rather than needing to query it from the database. Larger caches might be of interest when there is a big pool of ambient contracts that are consistently being fetched or used for non-consuming exercises. Larger caches can also benefit use cases where a big pool of contracts rotates through a create -> archive -> create-successor cycle. Consider adjusting these parameters explicitly if the performance of your specific workflow depends on large caches.

```
canton.participants.participant.ledger-api.index-service {
  max-contract-state-cache-size = 100000 // default 1e4
  max-contract-key-state-cache-size = 100000 // default 1e4
}
```

Max Transactions in the In-Memory Fan-Out

The `max-transactions-in-memory-fan-out-buffer-size` parameter controls the size of the in-memory fan-out buffer. This buffer allows serving the transaction streams from memory as they are finalized, rather than from the database. Make sure this buffer is large enough so applications are less likely to have to stream transactions from the database. In most cases, a 10s buffer works well. For example, if you expect a throughput of 20 tx/s, set this number to 200. The new default setting of 1000 assumes 100 tx/s. Consider adjusting these parameters explicitly if the performance of your workflow foresees transaction rates larger than 100 tx/s.

```
canton.participants.participant.ledger-api.index-service {
  max-transactions-in-memory-fan-out-buffer-size = 10000 // default 1000
}
```

34.7.7 Synchronization Domain Configurations

34.7.7.1 Public API

The sync domain configuration requires the same configuration of the `admin-api` as the participant. Next to the `admin-api`, we need to configure the `public-api`, which is the API where all participants connect.

TLS Encryption

As with the admin API, network traffic can (and should) be encrypted using TLS. This is particularly crucial for the public API.

An example configuration section which enables TLS encryption and server-side TLS authentication is given by:

```
canton.domains.acme.public-api {
  port = 5028
  address = localhost // defaults to 127.0.0.1
  tls {
    cert-chain-file = "./tls/public-api.crt"
    private-key-file = "./tls/public-api.pem"
    // minimum-server-protocol-version = TLSv1.3, optional argument
    // ciphers = null // use null to default to JVM ciphers
  }
}
```

If TLS is used on the server side with a self-signed certificate, we need to pass the certificate chain during the connect call of the participant. Otherwise, the default root certificates of the Java runtime will be used. An example would be:

```
participant3.domains.connect(
  domainAlias = "acme",
  connection = s"https://$hostname:$port",
  certificatesPath = certs, // path to certificate chain file (.pem) of server
)
```

Server Authentication

Canton has two ways to perform server authentication to protect from man-in-the-middle attacks: TLS and the sync domain ID.

If TLS is used on the public API as described above, TLS also takes care of server authentication. This is one of the core functions of TLS.

Server authentication can also be performed by the sync domain operator passing their sync domain identity to the participant node operator, and checking that the identity matches that reported by

the sync domain to the participant node. Like all nodes, the sync domain has an identity that corresponds to the fingerprint of its namespace root key. It reports its identity to connecting participant nodes and signs all its messages with keys authorized by that namespace root key on the topology ledger. Assuming no key compromises, this gives participants a guarantee that the reported identity is authentic. The domain identity of the sole connected sync domain can be read out using console commands like:

```
participant1.domains.list_connected.last.domainId.filterString
```

Client Authentication

Unlike the ledger or admin API, the public API uses Canton's cryptography and topology state for client authentication rather than mutual TLS (mTLS). Clients need to connect to the public API in several steps:

1. The client calls the `SequencerConnectService` to align on Canton Protocol versions and obtain the domain ID.
2. During the first connection, the client registers by sending its minimal topology state (identity, key delegations, public keys) to the domain manager.
3. The client calls the `SequencerAuthenticationService` to authenticate using a challenge-response protocol and get an access token for the other sequencer services.
4. The client connects to the main `SequencerService` using the access token from 3.

The information the client provides in step 2 is verifiable since it is a certificate chain of keys. The domain rejects this if the namespace root key fingerprint included is not permissioned (see [Permissioned Synchronization Domains](#)) or if the topology state provided is invalid.

During step 3, the client claims an identity, which is the fingerprint of a namespace root key. If that identity is registered (as done in step 2), the domain responds with a challenge consisting of a nonce and all fingerprints of signing keys authorized for that member as per the topology ledger. If the challenge is met successfully by signing the nonce appropriately with a key matching one of the authorized keys, the `SequencerAuthenticationService` responds with a time-limited token which can be used to authenticate more cheaply on the other public API services.

This authentication mechanism for the restricted services is built into the public sequencer API. You don't need to do anything to set this up; it is enforced automatically and can't be turned off.

The expiration of the token generated in step 2 is valid for one hour by default. The nodes automatically renew the token in the background before it expires. The lifetime of the tokens and of the nonce can be reconfigured using

```
canton.domains.mydomain.public-api {  
  token-expiration-time = 60m  
  nonce-expiration-time = 1m  
}
```

However, we suggest keeping the default values.

34.7.8 Usage of native libraries by Netty

Canton ships with native libraries (for some processor architectures: x86_64, ARM64, S390_64) so that the Netty network access library can take advantage of `epoll` on Linux, generally leading to improved performance and less pressure on the JVM garbage collector. The available native is picked up automatically and it falls back to the standard NIO library if running on unsupported operating systems or architectures.

Furthermore, the usage of the native library can also be switched off by setting the following:

```
-Dio.netty.transport.noNative=true
```

Even when this is expected, falling back to NIO might lead to a warning being emitted at `DEBUG` level on your log.

34.8 Sequencer Connections

Any member of a Canton network, whether a participant, mediator or topology manager, connects to the sync domain by virtue of connecting to a sequencer of that sync domain (there can be multiple thereof). The component managing this connection is called the `SequencerClient`.

A participant can connect to multiple sync domains (preview) simultaneously, but a mediator or topology manager will only connect to a single sync domain. Therefore, managing the sequencer connections of a participant differs slightly from managing a mediator or topology manager connection.

In the following sections, we explain how to manage such sequencer connections.

34.8.1 Participant Connections

The [sync domain connectivity commands](#) allow the administrator of a Canton node to manage connectivity to sync domains. Generally, the key command to add new connections is given by the [register command](#). While this is the command with the broadest ability to configure the connection, there are a few convenience macros that combine a series of steps to simplify administrative operations.

34.8.1.1 Connect Using Macros

Connect to Local Sequencers

When a participant should connect to a sequencer or sync domain that is running in the same process, you can use the `domains.connect_local` macro and provide the reference to the local node.

```
@ participant1.domains.connect_local(sequencer1)
```

The `connect_local` macro will generate the appropriate configuration settings for the provided sequencer and instruct the participant to connect to it using the `register` command.

Please note that you can also pass a local `DomainReference` to the `connect_local` call in case you are running an embedded sync domain.

Connect to Remote Sequencers

If you are connecting to a sequencer that is running on a remote host, you need to know the address and port the sequencer is configured to listen to. You can print out the port the sequencer is listening to using:

```
@ sequencer1.config.publicApi.port
res2: Port = Port(n = 30207)
```

You can also check that the address is set such that remote processes can connect to it:

```
@ sequencer1.config.publicApi.address
res3: String = "0.0.0.0"
```

By default, a sequencer will listen to 127.0.0.1, which is localhost. This is a safe default and it means that only processes running locally can connect to the sequencer (it is also set by default for the Ledger API and the Admin API). If you want to support remote processes connecting to the given sequencer, you need to explicitly configure it using:

```
// enable access of remote processes to the sequencer
canton.sequencers.sequencer1.public-api.address = 0.0.0.0
```

In this example, `sequencer1` and `sequencer2` are configured without TLS, whereas `sequencer3` is configured to use TLS:

```
@ sequencer3.config.publicApi.tls
res4: Option[TlsBaseServerConfig] = Some(
  value = TlsBaseServerConfig(
    certChainFile = ExistingFile(file = ./tls/sequencer3-127.0.0.1.crt),
    privateKeyFile = ExistingFile(file = ./tls/sequencer3-127.0.0.1.pem),
    minimumServerProtocolVersion = Some(value = "TLSv1.2"),
    ciphers = Some(
      value = List(
        "TLS_AES_256_GCM_SHA384",
        "TLS_CHACHA20_POLY1305_SHA256",
        "TLS_AES_128_GCM_SHA256",
        "TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384",
        "TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256"
      )
    )
  )
)
```

To connect to `sequencer3` using the `connect` macro, we need to create an URL string:

```
@ val port = sequencer3.config.publicApi.port
port : Port = Port(n = 30203)
```

```
@ val url = s"https://127.0.0.1:${port}"
url : String = "https://127.0.0.1:30203"
```

Please note that you need to adjust the `https` to `http` if you are not using TLS on the public sequencer Api. If the sequencer is using TLS certificates (e.g. self-signed) that cannot be automatically validated using your JVMs trust store, you have to provide the custom certificate such that the client can verify the sequencer public API TLS certificate. Let's assume that this root certificate is given by:

```
@ val certificatesPath = "tls/root-ca.crt"
certificatesPath : String = "tls/root-ca.crt"
```

You can now connect the participant to the sequencer using:

```
@ participant2.domains.connect("mydomain", connection = url, certificatesPath =
  ↪certificatesPath)
res8: DomainConnectionConfig = DomainConnectionConfig(
  domain = Domain 'mydomain',
  sequencerConnections = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(
    endpoints = https://127.0.0.1:30203,
    transportSecurity = true,
    customTrustCertificates
  ),
  manualConnect = false
)
```

Connect to High-Availability Sequencers

Important: [Daml Enterprise license](#) required

The Daml Enterprise version of Canton lets you connect a participant to multiple sequencers for the purpose of high availability. If one sequencer shuts down, the participant will then automatically fail over to the second sequencer.

Such a connection can be configured using the `connect_multi`:

```
@ participant3.domains.connect_multi("mydomain", Seq(sequencer1, sequencer2))
res9: DomainConnectionConfig = DomainConnectionConfig(
  domain = Domain 'mydomain',
  sequencerConnections = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(
    endpoints = Seq(http://0.0.0.0:30207, http://127.0.0.1:30205),
    transportSecurity = false
  ),
  manualConnect = false
)
```

On the read side, the participant will establish a subscription to one available sequencer to subscribe to the stream of encrypted messages. If the sequencer fails, the participant will automatically attempt to resubscribe to the next available sequencer. On the write path, the participant will send requests to all available sequencers in a round-robin manner, circling through the available sequencers. The same connectivity behavior applies to the domain manager and the mediator.

The [reference documentation](#) provides further information on how to connect to highly available sequencers, and the [high availability guide](#) has instructions on how to set up highly available sync domains.

Currently, all the sequencer connections used by a node need to be using TLS or not. A mixed mode where one sequencer is using TLS and another not is not supported.

Connect Using Register

The highest level of control over your sync domain connection is given by using `register` with a configuration of type `DomainConnectionConfig`. By default, the connection configuration only requires two arguments: the sync domain alias and the connection URL. In this guide, we cover all arguments.

First, we need to associate the sync domain connection to an alias. An alias is an arbitrary name chosen by the operator of the participant to manage the given connection:

```
@ val domainAlias = "mydomain"
domainAlias : String = "mydomain"
```

A sync domain alias is just a string wrapped into the type `DomainAlias`. This is done implicitly in the console, which allows you to use a string instead.

Next, you need to create a connection description of type `SequencerConnection`. The public sequencer API in Canton is based on gRPC, which uses HTTP 2.0. In this example, we build the URLs by inspecting the configurations:

```
@ val urls = Seq(sequencer1, sequencer2).map(_.config.publicApi.port).map(port =>
  ↪s"http://127.0.0.1:${port}")
urls : Seq[String] = List("http://127.0.0.1:30207", "http://127.0.0.1:30205")
```

However, the URL can also be entered as a string. A connection is then built using:

```
@ val sequencerConnectionWithoutHighAvailability = com.digitalasset.canton.
  ↪sequencing.GrpcSequencerConnection.tryCreate(urls(0))
sequencerConnectionWithoutHighAvailability : GrpcSequencerConnection =
  ↪GrpcSequencerConnection(endpoints = http://127.0.0.1:30207, transportSecurity =
  ↪false)
```

A second sequencer URL can be added using:

```
@ val sequencerConnection = sequencerConnectionWithoutHighAvailability.
  ↪addEndpoints(urls(1))
sequencerConnection : SequencerConnection = GrpcSequencerConnection(
  endpoints = Seq(http://127.0.0.1:30207, http://127.0.0.1:30205),
  transportSecurity = false
)
```

While the `connect` macros allow you to pass in a file path as an argument for the optional TLS certificate, you need to resolve this argument and load the certificate into a `ByteString` when working with `GrpcSequencerConnection`. There is a utility function that allows you to read a certificate from a file into a `ByteString` such that it can be used to create an appropriate sequencer connection:

```
@ val certificate = com.digitalasset.canton.util.BinaryFileUtil.
  ↪tryReadByteStringFromFile("tls/root-ca.crt")
certificate : com.google.protobuf.ByteString = <ByteString@196f0595 size=1960
  ↪contents="-----BEGIN CERTIFICATE-----\nMIIFeTCCA2GgAwIBAgI...">
```

```
@ val connectionWithTLS = com.digitalasset.canton.sequencing.
  ↪GrpcSequencerConnection.tryCreate("https://daml.com", customTrustCertificates =
  ↪Some(certificate))
connectionWithTLS : GrpcSequencerConnection = GrpcSequencerConnection(
```

(continues on next page)

(continued from previous page)

```

endpoints = https://daml.com:443,
transportSecurity = true,
customTrustCertificates
)

```

Next, you can assign a priority to the sync domain by setting the priority parameter:

```

@ val priority = 10 // default is 0 if not set
priority : Int = 10

```

This parameter is used to determine the sync domain to which a transaction should be sent if there are multiple sync domains connected (early access feature). The sync domain with the highest priority that can run a certain transaction will be picked.

Finally, when configuring a sync domain connection, the parameter `manualConnect` can be used when the sync domain should not be auto-reconnected on startup. By default, you would set:

```

@ val manualConnect = false
manualConnect : Boolean = false

```

If a sync domain connection is configured to be manual, it will not reconnect automatically on startup; it has to be reconnected specifically using:

```

@ participant3.domains.reconnect("mydomain")
res18: Boolean = true

```

Very security-sensitive users who do not trust TLS to check for the authenticity of the sequencer API can additionally pass an optional `domainId` of the target sync domain into the configuration. In this case, the participant will check that the sequencer it is connecting to can produce cryptographic evidence that it actually is the expected sync domain. The `domainId` can be obtained from the sync domain manager:

```

@ val domainId = Some(domainManager1.id)
domainId : Some[DomainId] = Some(value = domainManager1::12208d6e5925...)

```

These parameters together can be used to define a connection configuration:

```

@ val config = DomainConnectionConfig(domain = "mydomain", sequencerConnection, □
  manualConnect, domainId, priority)
config : DomainConnectionConfig = DomainConnectionConfig(
  domain = Domain 'mydomain',
  sequencerConnections = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(
    endpoints = Seq(http://127.0.0.1:30207, http://127.0.0.1:30205),
    transportSecurity = false
  ),
  manualConnect = false,
  domainId = domainManager1::12208d6e5925...,
  priority = 10
)

```

All other parameters are expert settings and should not be used. The `config` object can now be used to connect a participant to a sequencer:

```

@ participant4.domains.register(config)

```

34.8.1.2 Inspect Connections

You can inspect the registered sync domain connections using:

```
@ participant2.domains.list_registered()
res22: Seq[(DomainConnectionConfig, Boolean)] = Vector(
  (
    DomainConnectionConfig(
      domain = Domain 'mydomain',
      sequencerConnections = Sequencer 'DefaultSequencer' ->□
    ↪GrpcSequencerConnection(
      endpoints = https://127.0.0.1:30203,
      transportSecurity = true,
      customTrustCertificates
    ),
    manualConnect = false
  ),
  true
)
```

You can also get the aliases of the currently connected sync domains using:

```
@ participant2.domains.list_connected()
res23: Seq[ListConnectedDomainsResult] = Vector(
  ListConnectedDomainsResult(
    domainAlias = Domain 'mydomain',
    domainId = domainManager1::12208d6e5925...,
    healthy = true
  )
)
```

And you can inspect the configuration of a specific sync domain connection using:

```
@ participant2.domains.config("mydomain")
res24: Option[DomainConnectionConfig] = Some(
  value = DomainConnectionConfig(
    domain = Domain 'mydomain',
    sequencerConnections = Sequencer 'DefaultSequencer' ->□
    ↪GrpcSequencerConnection(
      endpoints = https://127.0.0.1:30203,
      transportSecurity = true,
      customTrustCertificates
    ),
    manualConnect = false
  )
)
```

34.8.1.3 Modify Connections

Sync domain connection configurations can be updated using the `modify` function:

```
@ participant2.domains.modify("mydomain", _.copy(priority = 20))
```

The second argument is a mapping function which receives as input argument a `DomainConnectionConfig` and needs to return a `DomainConnectionConfig`. Every case class has a default `copy` method that allows overriding arguments.

The `modify` command on the participant will only take effect after restarting the sync domain connection explicitly (or restarting the entire node):

```
@ participant2.domains.disconnect("mydomain")
```

```
@ participant2.domains.reconnect("mydomain")
res27: Boolean = true
```

On the mediator and sync domain manager node, the change is effected immediately.

Update a Custom TLS Trust Certificate

In some cases (in particular in test environments), you might be using self-signed certificates as a root of trust for the TLS sequencer connection. Whenever this root of trust changes, the clients need to update the custom root certificate accordingly.

This can be done through the following steps. First, you need to load the certificate from a file:

```
@ val certificate = com.digitalasset.canton.util.BinaryFileUtil.
  ↳ tryReadByteStringFromFile("tls/root-ca.crt")
certificate : com.google.protobuf.ByteString = <ByteString@37ca0af size=1960
  ↳ contents="-----BEGIN CERTIFICATE-----\nMIIFeTCCA2GgAwIBAgI...">
```

This step loads the root certificate from a file and stores it into a variable that can be used subsequently. Next, you create a new connection object, passing in the certificate:

```
@ val connection = com.digitalasset.canton.sequencing.GrpcSequencerConnection.
  ↳ tryCreate(url, customTrustCertificates = Some(certificate))
connection : GrpcSequencerConnection = GrpcSequencerConnection(
  endpoints = https://127.0.0.1:30203,
  transportSecurity = true,
  customTrustCertificates
)
```

Finally, you update the sequencer connection settings on the participant node:

```
@ participant2.domains.modify("mydomain", _.
  ↳ copy(sequencerConnections=SequencerConnections.single(connection)))
```

For mediators/sync domain managers, you can update the certificate accordingly.

34.8.1.4 Enable and Disable Connections

A participant can disconnect from a sync domain using:

```
@ participant2.domains.disconnect("mydomain")
```

Reconnecting to the sync domain can be done either on a per sync domain basis:

```
@ participant2.domains.reconnect("mydomain")
res32: Boolean = true
```

Or for all registered sync domains that are not configured to require a manual connection:

```
@ participant2.domains.reconnect_all()
```

34.8.2 Mediator and Synchronization Domain Manager

Both the mediator and the sync domain manager connect to the sync domain using sequencer connections. The sequencer connections are configured when the nodes are initialized:

```
@ mediator1.mediator.help("initialize")
initialize(domainId: com.digitalasset.canton.topology.DomainId, mediatorId: com.
↳digitalasset.canton.topology.MediatorId, domainParameters: com.digitalasset.
↳canton.admin.api.client.data.StaticDomainParameters, sequencerConnection: com.
↳digitalasset.canton.sequencing.SequencerConnection, topologySnapshot:□
↳Option[com.digitalasset.canton.topology.store.StoredTopologyTransactions[com.
↳digitalasset.canton.topology.transaction.TopologyChangeOp.Positive]],□
↳signingKeyFingerprint: Option[com.digitalasset.canton.crypto.Fingerprint]): com.
↳digitalasset.canton.crypto.PublicKey
Initialize a mediator
initialize(domainId: com.digitalasset.canton.topology.DomainId, mediatorId: com.
↳digitalasset.canton.topology.MediatorId, domainParameters: com.digitalasset.
↳canton.admin.api.client.data.StaticDomainParameters, sequencerConnections: com.
↳digitalasset.canton.sequencing.SequencerConnections, topologySnapshot:□
↳Option[com.digitalasset.canton.topology.store.StoredTopologyTransactions[com.
↳digitalasset.canton.topology.transaction.TopologyChangeOp.Positive]],□
↳signingKeyFingerprint: Option[com.digitalasset.canton.crypto.Fingerprint]): com.
↳digitalasset.canton.crypto.PublicKey
Initialize a mediator
```

The sequencer connection of a mediator and sync domain manager can be inspected using:

```
@ mediator1.sequencer_connection.get()
res35: Option[SequencerConnections] = Some(
  value = Sequencer 'DefaultSequencer' -> GrpcSequencerConnection(
    endpoints = http://0.0.0.0:30207,
    transportSecurity = false
  )
)
```

In some cases, the connection settings have to be updated. For this purpose, the two following functions can be used. First, the connection information can just be set using:

```
@ mediator1.sequencer_connection.set(sequencer1.sequencerConnection)
```

It can also be amended using:

```
@ mediator1.sequencer_connection.modify(_.addEndpoints(sequencer2.  
↪sequencerConnection))
```

Please note that the connection changes immediately, without requiring a restart.

34.9 Repair Nodes

The Canton platform is generally built to self-heal and automatically recover from issues. As such, if there is a situation where some degradation can be expected, there exists a mechanism that yields graceful degradation and automated recovery from said issues.

Common examples are database outages (retry until success) or network outages (failover and re-connect until success).

Canton reports such issues as warnings to alert the operator about the degradation of its dependencies, but generally, does not require any manual intervention to recover from a degradation.

However, not all situations can be foreseen and corruption of systems can always happen in unanticipated ways. Therefore, Canton can always be manually repaired. This means that whatever the corruption is, there is always a series of operational steps that can be made in order to recover the correct state of a node. If several nodes in the distributed system are affected, it may be necessary to coordinate the recovery among the affected nodes.

Conceptually, this means that Canton recovery is structured along the four layers:

1. Automated self-recovery and self-healing.
2. Recovery from crash or restart by re-creating a consistent state from the persisted store.
3. Standard disaster recovery from a database backup in case of database outage and replay from sync domain.
4. Corruption disaster recovery using repair and other console commands to re-establish a consistent state within the distributed system.

If you run into corruption issues, you need to first understand what caused the issue. Ideally, you can contact our support team to help you diagnose the issue and provide you with a custom recipe on how to recover from your issue (and prevent recurrence).

The toolbox the support engineers have at hand are:

- Exporting/importing secret keys
- Manually initializing nodes
- Exporting/importing DARs
- Exporting/importing topology transactions
- Manually adding or removing contracts from the active contract set
- Moving contracts from one sync domain to another
- Manually ignoring faulty transactions (and then using add/remove contract to repair the ACS).

All these methods are very powerful but dangerous. You should not attempt to repair your nodes on your own as you risk severe data corruption.

Keep in mind that the corruption of the system state may not have been discovered immediately; thus, the corruption may have leaked out through the APIs to the applications using the corrupted node. Bringing the node back into a correct state with respect to the other nodes in the distributed system can therefore make the application state inconsistent with the node's state. Accordingly, the

application should either re-initialize itself from the repaired state or itself offer tools to fix inconsistencies.

34.9.1 Preparation

As contracts (1) belong to parties and (2) are instances of Daml templates defined in Daml Archives (DARs), importing contracts to Canton also requires creating corresponding parties and uploading DARs.

Contracts are often interdependent requiring care to honor dependencies such that the set of imported contracts is internally consistent. This requires particular attention if you choose to modify contracts prior to their import.

Additionally, the use of [divulgence](#) in the original ledger could have likely introduced non-obvious dependencies that may impede exercising contract choices after import. As a result, such divulged contracts need to be re-divulged as part of the import (by exercising existing choices or, if there are no-side-effect-free choices that re-divulge the necessary contracts, by extending your Daml models with new choices).

Party IDs have a strict format on Canton ledgers ending with a required `fingerprint` suffix, so at a minimum, you will need to `remap` party IDs.

[Canton contract keys](#) do not have to be unique, so if your Daml models rely on uniqueness, consider extending the models using [these strategies](#) or limit your Canton participants to connect to a single [Canton sync domain with unique contract key semantics](#).

Canton does not support implicit party creation, so be sure to create all needed parties explicitly.

In addition you could choose to spread contracts, parties, and DARs across multiple Canton Participants.

With the above requirements in mind, you are ready to plan and execute the following three-step process:

1. Download parties and contracts from the existing Daml Participant Node and locate the DAR files that the contracts are based on.
2. Modify the parties and contracts (at the minimum assigning Canton-conformant party IDs).
3. Provision Canton participants along with at least one Canton sync domain. Then upload DARs, create parties, and finally the contracts to the Canton participants. Finally connect the participants to the sync domain(s).

34.9.2 Importing an actual Ledger

To follow along with this guide, ensure you have [installed and unpacked the Canton release bundle](#). Install and configure a postgres database for 2 sync domains and 4 participant nodes following the steps described in [Persistence using Postgres](#). Make sure that your Postgres has enough `max_connections` configured to serve effectively 6 Canton nodes as required by this example. Finally, run the following commands from the `canton-X.Y.Z` directory to set up the initial topology.

```
export CANTON=`pwd`
export CONF="$CANTON/config"
export IMPORT="$CANTON/examples/07-repair"
bin/canton \
  -c $IMPORT/participant1.conf, $IMPORT/participant2.conf, $IMPORT/participant3.
  ↪ conf, $IMPORT/participant4.conf \
  -c $IMPORT/domain-export-ledger.conf, $IMPORT/domain-import-ledger.conf \
```

(continues on next page)

(continued from previous page)

```
-c $CONF/storage/postgres.conf, $IMPORT/enable-preview-commands.conf \
--bootstrap $IMPORT/import-ledger-init.canton
```

This sets up an `exportLedger` with a set of parties consisting of painters, house owners, and banks along with a handful of paint offer contracts and IOUs.

Define the following helper functions useful to extract parties and contracts via the ledger api:

```
def queryActiveContractsFromDamlLedger(
  hostname: String,
  port: Port,
  templateFilter: Seq[TemplateId],
  tls: Option[TlsClientConfig],
  token: Option[String] = None,
)(implicit consoleEnvironment: ConsoleEnvironment): Seq[CreatedEvent] = {

  // Helper to query the ledger api using the specified command.
  def queryLedgerApi[Svc <: AbstractStub[Svc], Result](
    command: GrpcAdminCommand[_], Result
  ): Either[String, Result] =
    consoleEnvironment.grpcLedgerCommandRunner
      .runCommand("sourceLedger", command, ClientConfig(hostname, port, tls),
        token)
      .toEither

  (for {
    // Identify all the parties on the ledger and narrow down the list to local
    parties.
    allParties <- queryLedgerApi(
      LedgerApiCommands.PartyManagementService.
    ListKnownParties(identityProviderId = ""))
    localParties = allParties.collect {
      case PartyDetails(party, _, isLocal, _, _) if isLocal => LfPartyId.
    assertFromString(party)
    }

    // Query the ActiveContractsService for the actual contracts
    acs <- queryLedgerApi(
      LedgerApiCommands.AcsService
        .GetActiveContracts(
          localParties.toSet,
          templateFilter = templateFilter,
          limit = PositiveInt.MaxValue,
          timeout = NonNegativeDuration.maxTimeout,
          includeCreatedEventBlob = true,
        )(consoleEnvironment.environment.scheduler)
    )
  } yield acs.map(_.event)).valueOr(err =>
    throw new IllegalStateException(s"Failed to query parties, ledger id, or acs:
    $err")
  )
}

def removeCantonSpecifics(acs: Seq[CreatedEvent]): Seq[CreatedEvent] = {
  def stripPartyIdSuffix(suffixedPartyId: String): String =
```

(continues on next page)

(continued from previous page)

```

    suffixedPartyId.split(SafeSimpleString.delimiter).head

    acs.map { event =>
      ValueRemapper.convertEvent(identity, stripPartyIdSuffix)(event)
    }
  }

  def lookUpPartyId(participant: ParticipantReference, party: String): PartyId =
    participant.parties
      .list(filterParty = party + SafeSimpleString.delimiter)
      .map(_._party)
      .headOption
      .getOrElse(throw new IllegalArgumentException("Unknown party"))

```

As the first step, export the active contract set (ACS). To illustrate how to import data from non-Canton ledgers, strip the Canton-specifics by making the party ids generic (stripping the Canton-specific suffix).

```

val acs =
  queryActiveContractsFromDamlLedger(
    exportLedger.config.ledgerApi.address,
    exportLedger.config.ledgerApi.port,
    TemplateId
      .templateIdsFromJava(
        iou.Iou.TEMPLATE_ID_WITH_PACKAGE_ID,
        paint.OfferToPaintHouseByPainter.TEMPLATE_ID_WITH_PACKAGE_ID,
      ),
    exportLedger.config.ledgerApi.tls.map(_._clientConfig),
  )

val acsExported = removeCantonSpecifics(acs).toList

```

Step number two involves preparing the Canton participants and sync domain by uploading DARS and creating parties. Here we choose to place the house owners, painters, and banks on different participants.

Also modify the events to be based on the newly created party ids.

```

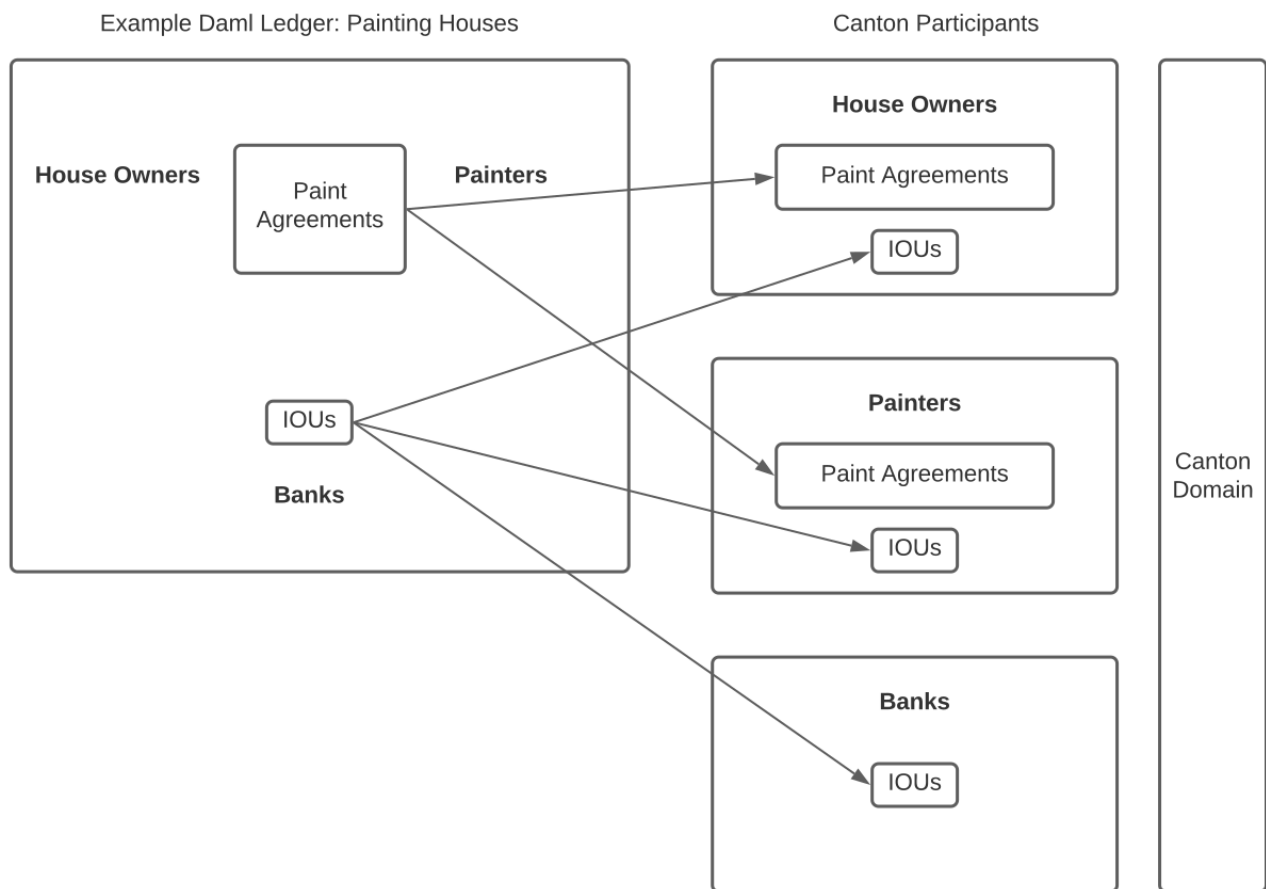

// Decide on which canton participants to host which parties along with their
// contracts.
// We place house owners, painters, and banks on separate participants.
val participants = Seq(participant1, participant2, participant3)
val partyAssignments =
  Seq(participant1 -> houseOwners, participant2 -> painters, participant3 ->
  banks)

// Connect to domain prior to uploading dars and parties.
participants.foreach { participant =>
  participant.domains.connect_local(importLedgerDomain)
  participant.dars.upload(darPath)
}

// Create canton party ids and remember mapping of plain to canton party ids.
val toCantonParty: Map[String, String] =
  partyAssignments.flatMap { case (participant, parties) =>

```

(continues on next page)

(continued from previous page)

```

    val partyMappingOnParticipant = parties.map { party =>
      participant.ledger_api.parties.allocate(party, party)
      party -> lookUpPartyId(participant, party).toLf
    }
    partyMappingOnParticipant
  }.toMap

// Create traffic on all participants so that the repair commands will pick an
// identity snapshot that is aware of
// all party allocations
participants.foreach { participant =>
  participant.health.ping(participant, workflowId = importLedgerDomain.name)
}

// Switch the ACS to be based on canton party ids.
val acsToImportToCanton =
  acsExported.map(ValueRemapper.convertEvent(identity, toCantonParty(_)))

```

As the third step, perform the actual import to each participant filtering the contracts based on the location of contract stakeholders and witnesses.

```

// Disconnect from domain temporarily to allow import to be performed.
participants.foreach(_ .domains.disconnect(importLedgerDomain.name))

// Pick a ledger create time according to the domain's clock.
val ledgerCreateTime =
  consoleEnvironment.environment.domains
    .getRunning(importLedgerDomain.name)
    .getOrElse(throw new IllegalArgumentException("No running domain node"))
    .clock
    .now
    .toInstant

// Specify protocol version used in the installation e.g. com.digitalasset.canton.
// version.ProtocolVersion.latest
val protocolVersion = testedProtocolVersion

val contractsWithRecomputedContractIds =
  utils
    .recompute_contract_ids(
      participant1,
      acsToImportToCanton.view
        .map(WrappedCreatedEvent)
        .map { event =>
          utils.contract_data_to_instance(event.toContractData, ledgerCreateTime)
        }
        .toSeq,
      protocolVersion,
    )
    ._1

val createdEventsAndContractsToImport =
  acsToImportToCanton zip contractsWithRecomputedContractIds

// Filter active contracts based on participant parties and upload.

```

(continues on next page)

(continued from previous page)

```

partyAssignments.foreach { case (participant, rawParties) =>
  val parties = rawParties.map(toCantonParty(_))
  val participantAcs = createdEventsAndContractsToImport.collect {
    case (event, contract)
      if event.signatories.intersect(parties).nonEmpty
        || event.observers.intersect(parties).nonEmpty
        || event.witnessParties.intersect(parties).nonEmpty =>
      repairContract(contract)
  }

  participant.repair.add(importLedgerDomain.name, participantAcs,
    ignoreAlreadyAdded = false)
}

```

Finally, reconnect to the sync domain.

```

participants.foreach(_._domains.reconnect(importLedgerDomain.name))

```

To demonstrate that the imported ledger works, let's have each of the house owners accept one of the painters' offers to paint their house.

```

def yesYouMayPaintMyHouse(
  houseOwner: PartyId,
  painter: PartyId,
  participant: ParticipantReference,
): Unit = {
  val iouContract = participant.ledger_api.javaapi.acs.await(iou.Iou.
    COMPANION)(houseOwner)
  val bank = iouContract.data.payer
  val paintProposal = participant.ledger_api.javaapi.acs
    .await(paint.OfferToPaintHouseByPainter.COMPANION)(
      houseOwner,
      pp => pp.data.painter == painter.toProtoPrimitive && pp.data.bank == bank,
    )
  val cmd = paintProposal.id
    .exerciseAcceptByOwner(iouContract.id)
    .commands
    .asScala
    .toSeq
  val _ = clue(
    s"$houseOwner accepts paint proposal by $painter financing through $bank"
  )(participant.ledger_api.javaapi.commands.submit(Seq(houseOwner), cmd))
}

// Have each house owner accept one of the paint offers to illustrate use of the
// imported ledger.
houseOwners.zip(painters).foreach { case (houseOwner, painter) =>
  yesYouMayPaintMyHouse(
    lookupPartyId(participant1, houseOwner),
    lookupPartyId(participant1, painter),
    participant1,
  )
}

```

(continues on next page)

(continued from previous page)

```
// Illustrate that acceptance of have resulted in
{
  val paintHouseContracts = painters.map { painter =>
    participant2.ledger_api.javaapi.acs
      .await(paint.PaintHouse.COMPANION) (lookUpPartyId(participant2, painter))
  }
  assert(paintHouseContracts.size == 4)
}
```

This guide has demonstrated how to import data from non-Canton Daml Participant Nodes or from a Canton Participant of a lower major version as part of a Canton upgrade.

34.9.2.1 Repairing Participants

Canton enables interoperability of distributed [participants](#) and [sync domains](#). Particularly in distributed settings without trust assumptions, faults in one part of the system should ideally produce minimal irrecoverable damage to other parts. For example if a sync domain is irreparably lost, the participants previously connected to that sync domain need to recover and be empowered to continue their workflows on a new sync domain.

This guide will illustrate how to replace a lost sync domain with a new sync domain providing business continuity to affected participants.

34.9.3 Recovering from a Lost Synchronization Domain

Note: Please note that the given section describes a preview feature, because using multiple sync domains is a preview feature.

Suppose that a set of participants have been conducting workflows via a sync domain that runs into trouble. In fact consider that the sync domain has gotten into such a disastrous state that the sync domain is beyond repair, for example:

- The sync domain has experienced data loss and is unable to be restored from backups or the backups are missing crucial recent history.

- The sync domain data is found to be corrupt causing participants to lose trust in the sync domain as a mediator.

Next the participant operators each examine their local state, and upon coordinating conclude that their participants' active contracts are mostly the same. This sync domain-recovery repair demo illustrates how the participants can

- coordinate to agree on a set of contracts to use moving forward, serving as a new consistent state,
- copying over the agreed-upon set of contracts to a brand-new sync domain,
- fail over to the new sync domain,
- and finally continue running workflows on the new sync domain having recovered from the permanent loss of the old sync domain.

34.9.4 Repairing an actual Topology

To follow along with this guide, ensure you have [installed and unpacked the Canton release bundle](#) and run the following commands from the `canton-X.Y.Z` directory to set up the initial topology.

```
export CANTON=`pwd`
export CONF="$CANTON/config"
export REPAIR="$CANTON/examples/07-repair"
bin/canton \
  -c $REPAIR/participant1.conf, $REPAIR/participant2.conf, $REPAIR/domain-repair-
  lost.conf, $REPAIR/domain-repair-new.conf \
  -c $CONF/storage/postgres.conf, $REPAIR/enable-preview-commands.conf \
  --bootstrap $REPAIR/domain-repair-init.canton
```

To simplify the demonstration, this not only sets up the starting topology of

two participants, `participant1` and `participant2`, along with one sync domain `lostDomain` that is about to become permanently unavailable leaving `participant1` and `participant2` unable to continue executing workflows,

but also already includes the ingredients needed to recover:

The setup includes `newDomain` that we will rely on as a replacement sync domain, and we already enable the `enable-preview-commands` configuration needed to make available the `repair.change_domain` command.

In practice you would only add the new sync domain once you need to recover from sync domain loss and also only then enable the repair commands.

We simulate `lostDomain` permanently disappearing by stopping the sync domain and never bringing it up again to emphasize the point that the participants no longer have access to any state from the sync domain. We also disconnect `participant1` and `participant2` from `lostDomain` to reflect that the participants have given up on the sync domain and recognize the need for a replacement for business continuity. The fact that we disconnect the participants at the same time is somewhat artificial as in practice the participants might have lost connectivity to the sync domain at different times (more on reconciling contracts below).

```
lostDomain.stop()
Seq(participant1, participant2).foreach { p =>
  p.domains.disconnect(lostDomain.name)
  // Also let the participant know not to attempt to reconnect to lostDomain
  p.domains.modify(lostDomain.name, _.copy(manualConnect = true))
}
```

Even though the sync domain is the node that has broken, recovering entails repairing the participants using the `newDomain` already set up. As of now, participant repairs have to be performed in an offline fashion requiring participants being repaired to be disconnected from the the new sync domain. However we temporarily connect to the sync domain, to let the topology state initialize, and disconnect only once the parties can be used on the new sync domain.

```
Seq(participant1, participant2).foreach(_.domains.connect_local(newDomain))

// Wait for topology state to appear before disconnecting again.
clue("newDomain initialization timed out") {
  eventually() {
    (
      participant1.domains.active(newDomain.name),
      participant2.domains.active(newDomain.name),
    ) shouldBe (true, true)
  }
}

// Run a few transactions on the new domain so that the topology state chosen by
↳the repair commands
// really is the active one that we've seen
participant1.health.ping(participant2, workflowId = newDomain.name)

Seq(participant1, participant2).foreach(_.domains.disconnect(newDomain.name))
```

With the participants connected neither to `lostDomain` nor `newDomain`, each participant can locally look up the active contracts assigned to the lost sync domain using the `testing.pcs_search` command made available via the `features.enable-testing-commands` configuration, and invoke `repair.change_domain` (enabled via the `features.enable-preview-commands` configuration) in order to move the contracts to the new sync domain.

```
// Extract participant contracts from "lostDomain".
val contracts1 =
  participant1.testing.pcs_search(lostDomain.name, filterTemplate = "^Iou",
↳activeSet = true)
val contracts2 =
  participant2.testing.pcs_search(lostDomain.name, filterTemplate = "^Iou",
↳activeSet = true)

// Ensure that shared contracts match.
val Seq(sharedContracts1, sharedContracts2) = Seq(contracts1, contracts2).map(
  _.filter { case (_, isActive, contract) =>
    contract.metadata.stakeholders.contains(Alice.toLf) &&
    contract.metadata.stakeholders.contains(Bob.toLf)
  }.toSet
)

clue("checking if contracts match") {
  sharedContracts1 shouldBe sharedContracts2
}

// Finally change the contracts from "lostDomain" to "newDomain"
participant1.repair.change_domain(
  contracts1.map(_.contractId),
  lostDomain.name,
  newDomain.name,
)
participant2.repair.change_domain(
  contracts2.map(_.contractId),
  lostDomain.name,
```

(continues on next page)

(continued from previous page)

```

newDomain.name,
skipInactive = false,
)

```

Note: The code snippet above includes a check that the contracts shared among the participants match (as determined by each participant, `sharedContracts1` by `participant1` and `sharedContracts2` by `participant2`). Should the contracts not match (as could happen if the participants had lost connectivity to the sync domain at different times), this check fails at soliciting the participant operators to reach an agreement on the set of contracts. The agreed-upon set of active contracts may for example be

the intersection of the active contracts among the participants
 or perhaps the union (for which the operators can use the `repair.add` command to create the contracts missing from one participant).

Also note that both the repair commands and the `testing.pcs_search` command are currently preview features, and therefore their names may change.

Once each participant has associated the contracts with `newDomain`, let's have them reconnect, and we should be able to confirm that the new sync domain is able to execute workflows from where the lost sync domain disappeared.

```

Seq(participant1, participant2).foreach(_.domains.reconnect(newDomain.name))

// Look up a couple of contracts moved from lostDomain
val Seq(iouAlice, iouBob) = Seq(participant1 -> Alice, participant2 -> Bob).map {
  case (participant, party) =>
    participant.ledger_api.javaapi.acs
      .await[iou.Iou.Contract, iou.Iou.ContractId, iou.Iou] (iou.Iou.COMPANION) (
        party,
        _.data.owner == party.toProtoPrimitive,
      )
}

// Ensure that we can create new contracts
Seq(participant1 -> ((Alice, Bob)), participant2 -> ((Bob, Alice))).foreach {
  case (participant, (payer, owner)) =>
    participant.ledger_api.javaapi.commands.submit_flat(
      Seq(payer),
      new iou.Iou(
        payer.toProtoPrimitive,
        owner.toProtoPrimitive,
        new iou.Amount(200.toBigDecimal, "USD"),
        java.util.List.of(),
      ).create.commands.asScala.toSeq,
    )
}

// Even better: Confirm that we can exercise choices on the moved contracts
Seq(participant2 -> ((Bob, iouBob)), participant1 -> ((Alice, iouAlice))).foreach
-> {
  case (participant, (owner, iou)) =>
    participant.ledger_api.javaapi.commands

```

(continues on next page)

(continued from previous page)

```
.submit_flat(Seq(owner), iou.id.exerciseCall().commands.asScala.toSeq)
}
```

In practice, we would now be in a position to remove the `lostDomain` from both participants and to disable the repair commands again to prevent accidental use of these dangerously powerful tools.

This guide has demonstrated how participants can recover from losing a sync domain that has been permanently lost or somehow become irreparably corrupted.

34.9.4.1 Repair Macros

Some operations are combined as macros, which are a series of consecutive repair commands, coded as a single command. While we discourage you from using these commands on your own, we document them here for the sake of completeness. These macros are available only in the enterprise edition.

34.9.5 Clone Identity

Many nodes can be rehydrated from a sync domain, as long as the sync domain is not pruned. In such situations, you might want to reset your node while keeping the identity and the secret keys of the node. This can be done using the repair macros.

You need local console access to the node. If you are running your production node in a container, you need to create a new configuration file that allows you to access the database of the node from an interactive console. Make sure that the normal node process is stopped and that nothing else is accessing the same database (e.g. ensure that replication is turned on). Also, make sure that the nodes are configured to not perform auto-initialization, as this would create a new identity. You ensure that by setting the corresponding auto-init configuration option to false:

```
canton.participants.myparticipant.init.auto-init = false
```

Then start Canton interactively using:

```
./bin/canton -c myconfig --manual-start
```

Starting with `--manual-start` will prevent the participant from attempting to reconnect to the sync domains. Then, you can download the identity state of the node to a directory on the machine you are running the process:

```
repair.identity.download(participant, tempDirParticipant)
repair.dars.download(participant, tempDirParticipant)
participant.stop()
```

This will store the secret keys, the topology state and the identity on the disk in the given directory. You can run the `identity.download` command on all nodes. However, mediator and sequencer nodes will only store their keys in files, as the sequencer's identity is attached to the sync domain identity and the mediator's identity is set only later during initialization.

The `dars.download` command is a convenience command to download all dars that have been added to the participant via the console command `participant.dars.upload`. Dars that were uploaded through the Ledger API need to be manually re-uploaded to the new participant.

Once the data is stored, stop the node and then truncate the database (please back it up before). Then restart the node and upload the identity data again:

```
participant.start()
repair.identity.upload(participant, tempDirParticipant)
repair.dars.upload(participant, tempDirParticipant)
```

Please note that dar uploading is only necessary for participants.

Now, depending on the node type, you need to re-integrate the node into the sync domain. For the sync domain nodes, you need to grab the static sync domain parameters and the sync domain ID from the sync domain manager. If you have remote access to the sync domain manager, you can run

```
val domainId = domainManager1.id
val domainParameters = domainManager1.service.get_static_domain_parameters
```

You also want to grab the mediator identities for each mediator using:

```
val mediatorId = mediator.id
```

For the sequencer, rehydration works only if the sync domain uses a blockchain; the database-only sequencers cannot rehydrate. So rehydration for blockchain-based sequencers will be:

```
repair.identity.upload(newSequencer, tempDirSequencer)
newSequencer.initialization.initialize_from_beginning(domainId, domainParameters)
newSequencer.health.wait_for_initialized()
```

For the sync domain manager, it looks like:

```
repair.identity.upload(domainManager2, tempDirDomainManager)
domainManager2.setup.init(
    SequencerConnections.single(newSequencer.sequencerConnection)
)
domainManager2.health.wait_for_initialized()
```

For the mediator, it would be:

```
repair.identity.upload(mediator, tempDirMediator)
mediator.mediator.initialize(
    domainId,
    mediatorId,
    domainParameters,
```

(continues on next page)

(continued from previous page)

```
SequencerConnections.single(newSequencer.sequencerConnection),  
topologySnapshot = None,  
)  
mediator.health.wait_for_initialized()
```

For a participant, you would reconnect it to the sync domain using a normal connect:

```
participant.domains.connect_local(sequencer)
```

Note that this will replay all transactions from the sync domain. However, command deduplication will only be fully functional once the participant catches up with the sync domain. Therefore, you need to ensure that applications relying on command deduplication do not submit commands during recovery.

34.9.6 Importing Existing Contracts

You may have existing contracts, parties, and DARs in other Daml Participant Nodes (such as the [Daml sandbox](#)) that you want to import into your Canton-based participant node. To address this need, you can extract contracts and associated parties via the ledger api, modify contracts, parties, and daml archived as needed, and upload the data to Canton using the [Canton Console](#).

You can also import existing contracts from Canton as that is useful as part of Canton upgrades across major versions with incompatible internal storage.

34.10 Decommissioning Canton Nodes and Sync Domain Entities

This guide assumes general familiarity with Canton, in particular [Canton identity management concepts](#) and [operations from the Canton console](#).

Note that, while onboarding new nodes is always possible, **a decommissioned node or entity is effectively disposed of and cannot rejoin a sync domain. Decommissioning is thus an irreversible operation.**

In addition, **decommissioning procedures are currently experimental**; regardless, **backing up nodes to be decommissioned before decommissioning them is strongly recommended.**

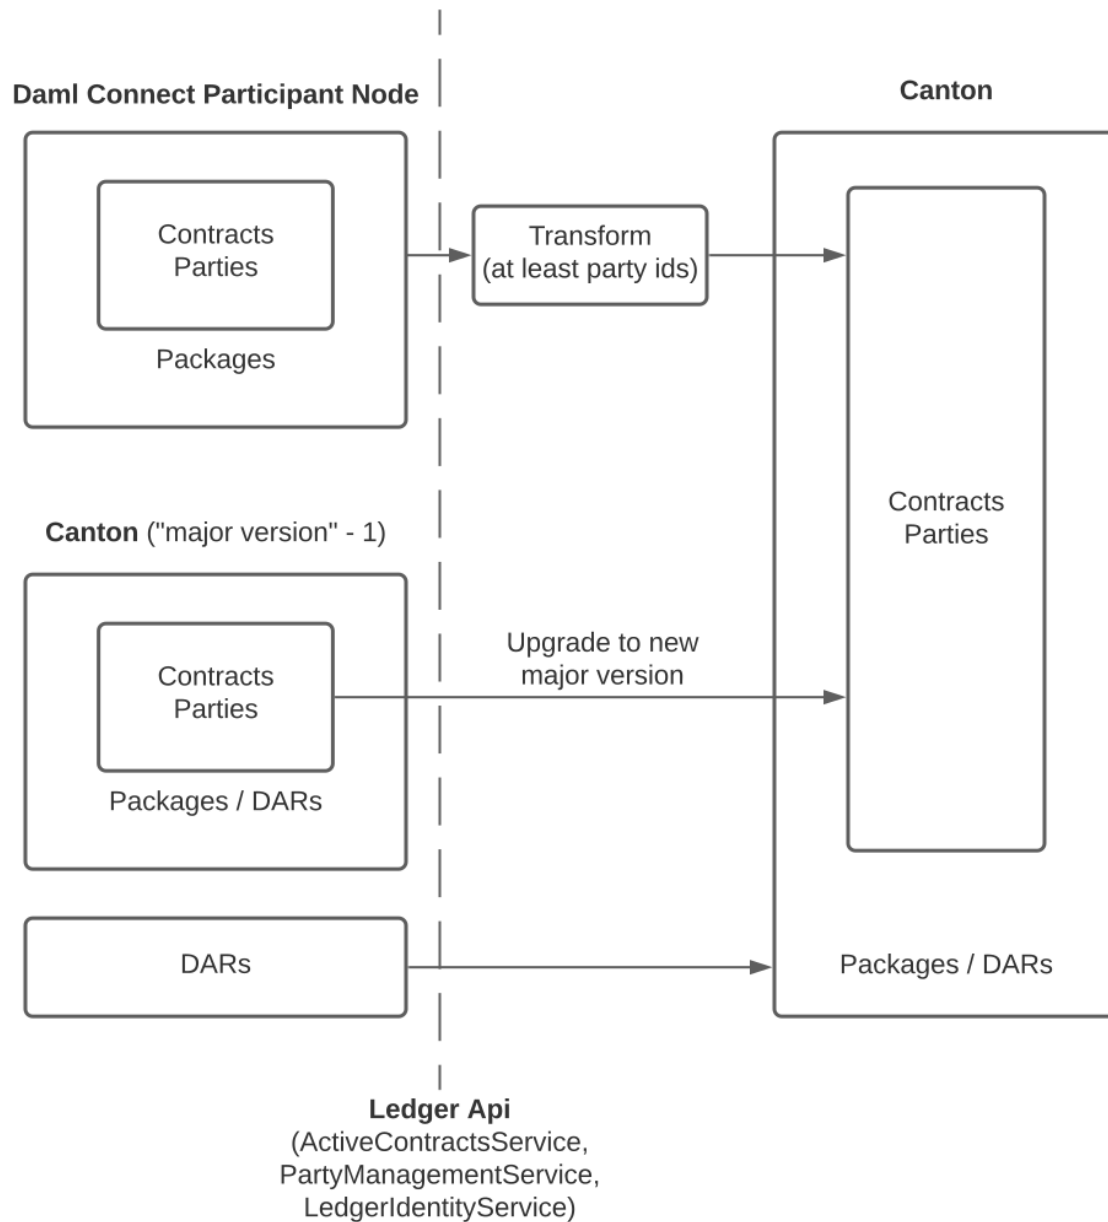

34.10.1 Decommissioning a Participant Node

34.10.1.1 Prerequisites

Be mindful that making a participant unavailable (by disconnecting it from the sync domain or decommissioning it) might block other workflows and/or prevent other parties from exercising choices on their contracts.

As an example, consider the following scenario:

- Party *bank* is hosted on participant *P1* and party *alice* is hosted on participant *P2*.
- An active contract exists with *bank* as signatory and *alice* as observer.
- P1* is decommissioned.

If *bank* is not multi-hosted, any attempt by *alice* to use the contract fails because *bank* cannot confirm. The contract remains active on *P2* forever unless purged via the repair service and only non-consuming choices and fetches can be committed.

Similar considerations apply if *P2* were to be decommissioned, even though *alice* is only an observer: if *alice* is not multi-hosted, the contract would remain active on *P1* until purged via the repair service and only non-consuming choices and fetches could be committed.

Additionally, when *P1* is decommissioned *P2* stops receiving ACS commitments from *P1*, which may prevent pruning. The same applies in reverse if *P2* is decommissioned.

Thus, properly decommissioning a participant requires the following high-level steps:

1. *Ensuring that the prerequisites are met*: ensure that active contracts and workflows using them are not stuck due to parties required to operate on them becoming unavailable.

Note: More specifically, for a contract action to be committed:

For `create` actions all stakeholders must be hosted on active participants.

For consuming `exercise` actions all stakeholders, actors, choice observers, and choice authorizers must be hosted on active participants.

The definition of `informee` is covered by the [ledger privacy model](#) section.

The exact prerequisites to be met in order to decommission a participant therefore depend on the design of the Daml application and should be accounted and tested for in the initial Daml design process.

2. *Decommissioning*: remove the participant from the topology state.

After that, the participant can be disposed of.

34.10.1.2 Decommissioning a participant once the prerequisites are met

1. Stop applications from sending commands to the Ledger API of the participant to be decommissioned to avoid failed commands and errors.
2. Disconnect the participant to be decommissioned from all sync domains as described in [enabling and disabling connections](#).
3. Use the `sequencer.disable_member` command to disable the participant being decommissioned in all sequencers and remove any sequencer data associated with it.
4. Use the `topology.participant_domain_states.authorize` command to remove the participant from the domain topology via the domain manager.

The following code snippet demonstrates the last two steps:

```
// Disable the participant on all the sequencers to remove any sequencer data
// associated with it
// and allow sequencer pruning
sequencers.all.foreach(_.sequencer.disable_member(participant2))

// Remove the participant from the topology
domain.topology.participant_domain_states.authorize(
  TopologyChangeOp.Remove,
  domainId,
  participant2.id,
```

(continues on next page)

(continued from previous page)

```
RequestSide.From,
)
```

34.10.2 Decommissioning a Sequencer

Sequencers are part of a sync domain's messaging infrastructure and do not store application contracts, so they are disposable as long as precautions are taken to avoid disrupting the synchronization services. This means, concretely, ensuring that:

1. No active participant nor active mediator is connected to the sequencer to be decommissioned.
2. All active participants and mediators are connected to an active sequencer.

After that, the sequencer can be decommissioned by removing it from the sync domain's topology and finally disposed of.

34.10.2.1 Disconnecting all nodes from the sequencer to be decommissioned

Change the sequencer connection on the mediators connected to the sequencer to be decommissioned to use another active sequencer, as per [mediator and domain manager connectivity](#):

```
val conn1 = sequencer1.sequencerConnection
mediator1.sequencer_connection.set(SequencerConnections.single(conn1))
```

Change the domain manager's sequencer connection to another active sequencer, using the [sequencer_connection.set](#) command:

```
val conn1 = sequencer1.sequencerConnection
domainManager1.sequencer_connection.set(conn1)
```

Reconnect participants to the sync domain, as described in [domain connectivity](#), using a sequencer connectio to another active sequencer:

```
participant2.domains.disconnect(domainAlias)
participant2.domains.modify(
  domainAlias,
  _.copy(sequencerConnections = SequencerConnections.single(sequencer1.
    ↪sequencerConnection)),
)
participant2.domains.reconnect(domainAlias)
```

34.10.2.2 Decommissioning the sequencer

Sequencers are part of the sync domain by virtue of having their node ID equal to the domain ID, which also means they all have the same node ID. Since a sequencer's identity is the same as the sync domain's identity, you should leave identity and namespace mappings intact.

However, a sequencer may use its own cryptographic material distinct from other sequencers. In that case, owner-to-key mappings must be removed for the keys it exclusively owns:

1. Find the keys on the sequencer to be decommissioned using the [keys.secret.list](#) command.

2. Among those keys, find the ones not shared by other sequencers. You can do this by issuing the `keys.secret.list` command on each of them: the fingerprints that appear only on the sequencer node to be decommissioned correspond to its exclusively-owned keys.
3. Remove the mappings for its exclusively owned keys using the `topology.owner_to_key_mappings.authorize` command.

```
def keyIdAndPurpose(privateKeyMetadata: PrivateKeyMetadata) =
  (privateKeyMetadata.id, privateKeyMetadata.purpose)

val sequencer2KeyIdsAndPurposes = sequencer2.keys.secret.list().
  ↪map(keyIdAndPurpose)
val sequencer2ExclusiveKeyIdsAndPurposes =
  sequencer2KeyIdsAndPurposes.toSet.diff(
    sequencers.all
      .filter(_.name != sequencer2.name)
      .flatMap(_.keys.secret.list())
      .map(
        keyIdAndPurpose
      )
      .toSet
  )
sequencer2ExclusiveKeyIdsAndPurposes.foreach { case (keyId, keyPurpose) =>
  domainManager1.topology.owner_to_key_mappings
    .authorize(
      TopologyChangeOp.Remove,
      sequencer2.id,
      keyId,
      keyPurpose,
    )
}

// Avoids error logs in the decommissioned sequencer that are to be expected but
↪may be confusing
sequencer2.stop()

// The increased timeout is needed here: once the sequencer is stopped, the other
↪sequencers
// need a bit of time to mark it as offline.
participant1.health.ping(participant2, timeout = 30.seconds)

// The sequencer and the locally stored cryptographic material can now be
↪disposed of
```

Finally, the cryptographic material exclusively owned by a decommissioned sequencer must also be disposed of:

If it was stored only on the decommissioned sequencer, it must be disposed of together with the decommissioned sequencer node.

However, if a decommissioned sequencer's cryptographic material is managed via a KMS system, it must be disposed of through the KMS; refer to your KMS' documentation and internal procedures to handle this. KMS-managed cryptographic material of sequencer nodes.

34.10.3 Decommissioning a Mediator

Mediators are also part of a sync domain's messaging infrastructure and do not store application contracts, so they are disposable as long as precautions are taken to avoid disrupting the synchronization services. This means ensuring that at least one mediator remains on the sync domain.

If other mediators exist on the sync domain, a mediator can be decommissioned using a single console command [setup.offboard_mediator](#).

```
// `setup.offboard_mediator` will log a warning with a message similar to the
↳following:
//
// "Mediator ... is deactivated and will miss out on topology transactions. This
↳will break it"
//
// This just means that the decommissioned mediator won't be able to join the
↳domain anymore, as it won't receive
// topology transactions and its topology state will thus fork, which is an
↳irreversible fault.
// Off-boarding a mediator is indeed an irreversible operation, but here it is
↳being intentionally and explicitly
// requested, so in this case this warning can be safely ignored.
domainManager.setup.offboard_mediator(mediatorId)
mediator.stop()
```

Chapter 35

Troubleshooting Guide

35.1 Introduction

Distributed systems can fail in many ways and finding the cause of an error is not straightforward. This guide here captures the common steps our engineers take when trying to troubleshoot issues found during development or support.

35.2 Enable Information Gathering

The following switches/steps should be taken to improve analyzing errors. Without these, you might not be able to diagnose harder issues.

Create Health Dumps

Ensure that you can create [Health Dumps](#). You need to share these health dumps during any support request. The health dumps provide a lot of diagnostic information that we need to troubleshoot issues.

Turn on Debug Logging

Turn on debug logging by starting the process with:

```
./bin/canton -v
```

or even:

```
./bin/canton --debug
```

The `-v` flag will turn on debug logging of all `com.digitalasset.canton` loggers, whereas `--debug` will turn on debug logging of all libraries too. Please also see [Logging](#).

Turn on Detailed API Logging

You might want to turn on [detailed api logging](#). This will write all incoming commands and the outgoing data into the log file and it will allow you to inspect the details of a command that leads to failures. Beware that if your commands contain sensitive data, this data will then be written to the log file.

Turn on metrics collection

See *Canton Metrics* <canton-metrics>. If you don't have a metrics system, you can report metrics to CSV files and JMX beans by configuring:

```

metrics.report-jvm-metrics = true

canton.monitoring.metrics.reporters = [{
  type = csv
  directory = "metrics"
  interval = 5s
  filters = [{
    contains = "canton.updates-published"
  }, {
    contains = "sequencer-client.event-handle"
  }, {
    contains = "sequencer.processed"
  }, {
    contains = "executor.queued"
  }, {
    contains = "executor.running"
  }, {
    contains = "executor.waittime"
  }, {
    contains = "jvm.memory_usage.heap"
  }, {
    contains = "jvm.memory_usage.non-heap"
  }, {
    contains = "jvm.thread_states"
  }]
}, {
  type = jmx
}]

```

This will periodically write selected metrics to CSV files (one file per metric). It will also expose all available metrics as JMX beans; therefore, you can use VisualVM to look at metric values.

The CSV reporter needs to have a `filters` parameter, because otherwise Canton will report all available metrics, which would substantially slow-down Canton. The JMX reporter does not need a `filters` parameter, because JMX beans only get evaluated when you actually look at them using VisualVM. So the JMX reporter is great for exploring different metrics initially. The CSV reporter is preferable, if you want to record metrics without human intervention.

Turn on database query cost monitoring

Enable `canton.monitoring.log-query-cost.every = 60s`. This will capture query cost statistics and might help diagnose latency / indexing issues with your database, as explained in [How to Diagnose Slow Database Queries](#).

Turn on slow futures supervision

Enable `canton.monitoring.log-slow-futures = yes` which will track some operations and alert if they are taking too long (disabled by default to reduce the overhead).

Do not disable deadlock detection (enabled by default)

Deadlock detection (`canton.monitoring.deadlock-detection`) will periodically test if the JVM executes new tasks in a timely manner. It will log the following warning, if this is not the case: *Task runner <name> is stuck or overloaded for 5s* . Failure of this check may indicate that the CPU is overloaded, the execution context is too small. Usually the check resolves itself with a subsequent log message: *Task runner <name> is just overloaded, but operating correctly. Task got executed in the meantime*. If this message does not appear, all available threads are blocked for some reason. Their

stack-traces will be logged additionally. However, all threads being blocked are not common. They should not happen. Therefore, normally this check just indicates that your system is overloaded.

Configure delay logging

Delay logging (`canton.monitoring.delay-logging-threshold`, default 20s) will log a warning, if a node falls behind with processing messages from the sequencer. Such a warning indicates that the node is overloaded. As a rule of thumb, configure the maximum latency, i.e., the maximum time it should take Canton to process a command.

Do not disable trace context propagation (enabled by default)

Every request will receive a unique trace id. The trace id is included in log messages referring to that request. If trace context propagation is enabled (`canton.monitoring.tracing.propagation = enabled`), different nodes will use the same trace id for a request. This makes it easier for you to identify log messages across different nodes that refer to the same request.

35.3 Key Knowledge

Canton Transaction Processing Steps

Canton transaction processing has the following key steps involved. When we debug, we obviously try to find out which of the steps fails / is slow / faulty. This can help you to narrow down the component and the issue. As all the message exchange happens via the sequencer, you effectively observe whether the information came into the node and where the action that the node was supposed to take was taken by responding with a message to the sequencer (or emitting a command result on the ledger api). The phases are:

- Phase 1: Submitting participant prepares the confirmation request based on the Daml command input . The confirmation request is sent to the sequencer, addressing the mediator and the validating participants.
- Phase 2: The mediator receives the request from the sequencer, registers the transaction and starts to wait for confirmations.
- Phase 3: The validating participants receive the confirmation request from the sequencer and perform their validations. The two main checks that happen here are: validation (is the transaction correct and properly authorized?) & conflict detection (are all contracts that are spent or fetched in the transaction still active?).
- Phase 4: The confirming participants, a subset of the validating participants, send their verdict on each sub-transaction they are privy via the sequencer to the mediator. The verdict can be `LocalApprove` or some rejection reason.
- Phase 5: The mediator receives the mediator responses (approvals and rejections) from the participants via the sequencer and validates them. If the mediator receives enough responses for the given transaction, it will compute the `Verdict` , which is the final decision on the transaction.
- Phase 6: The mediator sends its verdict to all validating participants of a transaction via the sequencer.
- Phase 7: The participants receive the mediator verdict and register it to the record order publisher. While the validation can happen in parallel, the record publisher will ensure that the transactions are emitted in order.

For each phase a log line that should appear at the beginning and one that appears at the end of the phase.

Internal Errors

If internal consistency checks fail and indicate a possible bug in Canton, Canton will include the term `internal error` into the log message. Please contact support, if you see an internal error.

Canton Error Codes

All non-internal warnings and errors are *logged consistently* (or at least we aspire to do). The error code information listed in the documentation should contain all information you need in order to understand and possibly resolve the issue.

35.4 Log Files

Canton Trace Ids

All Canton log statements contain a *trace-id*. This tracing is turned on by default and the `trace-id` is passed between the distributed processes:

```
c.d.c.p.p.s.InFlightSubmissionTracker:participant=participant1
tid:d5df95972a95b5ff00cb5cc3346c545f - NOT_SEQUENCED_TIMEOUT(2,
  ↳d5df9597):
Transaction was not sequenced within the pre-defined max sequencing
  ↳time and has
therefore timed out err-context:{location=SubmissionTrackingData.
  ↳scala:175,
timestamp=2022-10-19T17:45:56.393151Z}
```

In above example, we see the trace id twice: `tid:d5df95972a95b5ff00cb5cc3346c545f` and `NOT_SEQUENCED_TIMEOUT(2,d5df9597)`. By filtering according to the trace-id, you can find almost all log statements that relate to a particular command. However, sometimes, we also need to find out the command id of a transaction. You can do that by grepping for the `rosetta stone`, which is one particular log line that contains both strings:

```
2023-07-04 12:03:26,517 [□] INFO
c.d.c.p.a.s.c.CommandSubmissionServiceImpl:participant=participant1
tid:35e389f0e41fd0273443dd866ff9e347 - Submitting commands for
  ↳interpretation,
commands -> {readAs: [], deduplicationPeriod: {duration: 'PT168H'},
submittedAt: '2023-07-04T10:03:26.514885Z', ledgerId: 'participant1',
applicationId: 'CSsubmitAndWaitBasic',
submissionId: 'CSsubmitAndWaitBasic-alpha-410b4d7b1b585-submission-0',
actAs: ['CSsubmitAndWaitBasic-alpha-410b4d7b1b585-party-
  ↳0::122035bd93d74879ce582adf5aa04a809b4b20618d39c1a9c2a17d35c29ab1ed098f
  ↳'],
commandId: 'CSsubmitAndWaitBasic-alpha-410b4d7b1b585-command-0',
workflowId: 'CSsubmitAndWaitBasic-410b4d7b1b585'}.
```

The first string is again the trace id. Additionally, the `commandId` of the transaction, the `applicationId`, the `submissionId` and the `workflowId` are logged and can be used to filter the logs.

Extract the Context of a Log Message

The log lines often also contain the `context` of the component. Examples:

- This log line tells us which component of which participant (`participant1`) of which sync domain connection (`da`) has been emitting this log line. It also includes the trace ID of the underlying request:

```
2022-10-04 15:55:50,077 [ ] DEBUG
c.d.c.p.p.TransactionProcessingSteps:participant=participant1/
↳domain=da
tid:461cae6245cfaadc87c2481a17d7e1bb - Preparing batch for
↳transaction
submission
```

- During tests, the log line includes the name of the test. In this case, it is SimplestPingIntegrationTestInMemory:

```
:: 2022-10-04 15:55:50,077 [ ] DEBUG c.d.c.p.p.
↳TransactionProcessingSteps:SimplestPingIntegrationTestInMemory/
participant=participant1/domain=da
↳tid:461cae6245cfaadc87c2481a17d7e1bb
- Preparing batch for transaction submission
```

Compare with a Happy Path Successful Logging Trace

Many components will log something and it is impossible to document every micro-step that happens (as this is also subject to change). But it makes sense to compare a failure trace with a successful transaction trace. To get such a trace, you start up a `canton simple topology` example setup and run a simple:

```
participant1.health.ping(participant2)
```

You then open the log file and filter for the command processing of that ping (search for `Starting ping`). This will give you a clean happy path trace. You can then subsequently compare your failure trace to the happy-path trace and look for the differences, i.e. where did the steps start to take a different path etc.

Use the API Request Logger to Locate the Component

One key logging component is the `ApiRequestLogger`. This component is injected into the GRPC library and will log every incoming and outgoing request / message. Therefore, we can easily observe when a transaction left a node and when it arrived at a subsequent node. If api logging is turned on, the api request logger will print the full detail of all the GRPC messages into the log files.

35.5 Using LNAV to View Log Files

Setup and Use LNAV

Setup lnav for viewing logs as described in [viewing logs](#). It will require a few minutes to get used to it, but the payoff of this investment is great and comes fast. **In particular get familiar with loading multiple files, filtering, searching and jumping to errors.**

Open Multiple Log Files in one LNAV Session

Generally, when you start reading log files, then open the log files of all involved nodes in a single lnav session (if the files are small enough): `lnav participant1.log domain.log participant2.log`

Split Log Files if they are too big

If your log files are too big the unix utility `split` can be used to split the file into chunks.

Uncompress GZ Log files for faster reading

Normally, log files are compressed when you get them. Lnav works much better and faster if you pass uncompressed files on the command line.

Easily Navigate to the First Logged Error

Then hit `g` to go to the beginning of the file and subsequently `w` or `e` to get to the first warning or error. Usually, the first error gives you the hint on what is going on.

Look at All Warnings and Errors

Canton's error reporting has been designed to log a warning/error whenever it detects that something is not working as it should. Therefore, any problem will likely show up in the log file. On the flip side, Canton may log a huge number of warnings/errors, in particular if a node or the database goes down. If the first warning or error does not completely explain the situation, it is important to look at all such messages. Use the following recipe:

1. Set the minimum log level to WARN to display only warnings and errors (`:set-min-log-level warn`).
2. Look at the first message. Mark the message (pressing `m`) so you can later get back to the message.
3. Define an out-filter to hide the first message and all similar messages.
4. Repeat steps (2) and (3) until you have filtered out all messages.
5. Disable all out-filters. You can now press `u` and `U` to step through all marked warning and error messages.

Filter Irrelevant Items

One useful strategy when working with logs is to continuously remove lines that are not relevant, adding `filter-out` until only the relevant log messages remain.

Show Gap In Logging Times

Once you start filtering for a particular command trace, you might want to hit `shift-t`. This will show you the delta time between the first log line and the subsequent one. Usually, you just need to find the `gap`. This will tell you immediately where something got stuck / slow / timed out:

- open the log files of all components
- search for the first error / warn (i.e. hit `w` or `e`)
- pick the trace-id (as described above) and filter for it
- hit `shift-t` and find the gap.

35.6 Setup Issues

Connect to each node and check the status: `<node> .health.status`

Are the nodes up and running?

Are the nodes [connected to a sequencer](#)? Errors that often happen here are:

- `public-apis` / `ledger-api` addresses are not set to `0.0.0.0` and are still binding to `localhost` (default value for security reasons).
- you are using TLS on the server side, but on the client side you have defined the URL as `http://`.
- the chosen port is not correct.

If you are running into TLS connectivity issues, turn on `-debug` and check the detailed netty logs for hints. These libraries tend to log necessary information only on debug level. You can also increase the debugging information level by starting canton with `-Djavax.net.debug=all`.

Try to confirm that your setup works by running a ping:

```
participant1.health.ping(participant2)
```

35.7 Timeout Errors

Any transaction that is submitted to Canton will either be successfully worked off (accepted or rejected), or eventually timeout. If a transaction hits a timeout, the application will be informed by an appropriate completion event on the Ledger API about the rejection reasons. We can hit the following timeouts in Canton (you can get further timeouts from the [command service](#)):

```
NOT_SEQUENCED_TIMEOUT
LOCAL_VERDICT_TIMEOUT
MEDIATOR_SAYS_TX_TIMED_OUT
LOCAL_VERDICT_LEDGER_TIME_OUT_OF_BOUND
LOCAL_VERDICT_SUBMISSION_TIME_OUT_OF_BOUND
```

Such a timeout usually means that some component is either:

- offline - resolve by checking that all nodes are healthy (`health.status()`) and are connected with each other.
- overloaded - resolve by tuning according to our [performance configuration guide](#).
- unable to complete the transaction processing within the given time (i.e. transactions are too big) - resolve by increasing the timeouts as described in our [performance configuration guide](#).

Use a ping to determine if your system is broken or just slow / overloaded / contentious

Many issues only surface under high load. Therefore, it often makes sense to diagnose timeout issues using a:

```
participant1.health.ping(...)
```

while the system is idle. If the ping works, then you have likely a throughput / performance / contention issue and you should use one of the other guides to continue debugging.

If the ping doesn't work and never did before, you should check the setup troubleshooting guide.

If previously, transaction processing worked and now stopped working, while all nodes are up and running, and reporting to be healthy, you should raise an issue with support.

By turning on diagnostics information collection as explained above, you can then figure out which step of transaction processing failed by comparing the trace in the logs to the Phase 1-7 explanation, isolating out which component did not respond.

35.8 Auth Errors

For security reasons, Canton removes all details from auth errors. On the client side, you usually only see `PERMISSION_DENIED/An error occurred`. Please contact the operator and inquire about the request `<no-correlation-id>`, so you need to inspect server logs to debug auth errors.

To use an auth-enabled ledger api, the caller needs to attach an access token to the gRPC request. These tokens are attached in the `Authorization` HTTP header. To see headers attached to incoming

and outgoing requests, you need to set the log level to `TRACE`. `ApiRequestLogger` will then output log lines containing `received headers` or `sending response headers`.

Filter-in expressions for `Inav`:

```
com.digitalasset.canton.ledger.api.auth.Authorizer
c.d.l.a.a.i.AuthorizationInterceptor
c.d.c.n.g.ApiRequestLogger
```

Common patterns from the canton log:

```
PERMISSION_DENIED(7,0): Could not resolve is_deactivated status for
user
```

You are using a token for a user that is not (yet) allocated. The log line contains the name of the user that needs to be allocated.

```
PERMISSION_DENIED(7,0): Claims are only valid for applicationId
```

You are using a wrong application Id when submitting commands. The log line contains the expected application ID. Note that the application ID must be equal to the daml user name when using ledger API access tokens.

```
UNAUTHENTICATED(6,0): The command is missing a (valid) JWT token
```

You did not attach a token to the request, or the token could not be decoded. Use [JWT.IO](#) to verify that the token string is a valid JWT.

```
PERMISSION_DENIED(7,0): Claims do not authorize to act as party
```

The log line contains the name of the missing claim, but not the actual claims. When using tokens based on user names ([Audience Based Tokens](#) and [Scope Based Tokens](#)), consult the user management service to see whether you need to grant more rights to the user. When using tokens based on party names ([Custom Claims Access Tokens](#)), debug the token in [JWT.IO](#).

35.9 Disconnections

Intermittent network failures cause the majority of disconnections that occur in real-life scenarios. Less frequently, disconnections happen when network proxies, load balancers, or other elements of the network infrastructure terminate the client-server connection because they think that there is no activity going on in the communication channel. Such disconnections are predictable and can be avoided by carefully configuring the components' keep-alive parameters.

There are two keep-alive mechanisms to consider for the GRPC protocol stack: the low-level TCP keep-alive feature and the HTTP/2 pings. Canton endpoints utilize the latter. The article describing [how to use HTTP/2 PING-based keep-alives](#) is a good place to become familiar with the basics of this mechanism.

The keep-alive parameters have to be set on all components involved. In this example we concentrate on configuring the Ledger API, but a similar approach can be used for other Canton APIs. This is described in the dedicated [keep-alive article](#). Next, change the corresponding parameters on the Ledger API client. Consult the user manual specific to your application. The parameters on both ends should be set consistently, and the keep-alive time setting on the client should not be set lower than the `permit-keep-alive-time` of the Ledger API server.

Finally, select the settings of the proxies between the client and the server. Again, the user manual specific to each component is the best place to learn how to manage these settings. The proxy inactivity timeouts should be more lenient than the client and server settings.

You can determine if disconnections are caused by a misalignment of keep-alive settings on different components by enabling detailed networking logging on the Ledger API server. If the specific implementation allows, simultaneously increase the log level in the client application. If the client is written on the Java stack, you can probably apply a similar approach to that you would use in the Canton participant.

The easiest way to start the keep-alive logging is to start Canton Participant with the `--debug` flag. Alternatively, you can modify the logger's configuration in the `logback.xml` file. You then have to bump the log level of the `io.grpc.netty.NettyServerHandler` the `io.grpc.netty.NettyClientHandler` and the `com.digitalasset.canton.platform.apiserver.GrpcConnectionLogger` to `DEBUG`.

Once that is done, you can observe the lifecycle events of the underlying GRPC channels such as their opening and closing:

```
[...] DEBUG c.d.c.p.a.GrpcConnectionLogger:participant=participant - Grpc
  ↳ connection open: {io.grpc.Grpc.TRANSPORT_ATTR_LOCAL_ADDR=/127.0.0.1:5001,
io.grpc.internal.GrpcAttributes.securityLevel=NONE, io.grpc.Grpc.TRANSPORT_ATTR_
  ↳ REMOTE_ADDR=/127.0.0.1:49944}
[...] DEBUG c.d.c.p.a.GrpcConnectionLogger:participant=participant - Grpc
  ↳ connection closed: {io.grpc.Grpc.TRANSPORT_ATTR_LOCAL_ADDR=/127.0.0.1:5001,
io.grpc.internal.GrpcAttributes.securityLevel=NONE, io.grpc.Grpc.TRANSPORT_ATTR_
  ↳ REMOTE_ADDR=/127.0.0.1:49944}
```

Likewise, you can observe the header and data frames being exchanged. That is the essence of the GRPC interchange.

```
[...] DEBUG io.grpc.netty.NettyServerHandler - [id: 0xc6d471d0, L:/127.0.0.1:5001 -
  ↳ R:/127.0.0.1:52722] INBOUND HEADERS: streamId=3
headers=GrpcHttp2RequestHeaders[:path: /com.daml.ledger.api.v1.TransactionService/
  ↳ GetTransactions, :authority: localhost:5001, :method: POST,
:scheme: http, te: trailers, content-type: application/grpc, user-agent: grpcurl/
  ↳ v1.8.7 grpc-go/1.48.0] padding=0 endStream=false

[...] DEBUG io.grpc.netty.NettyServerHandler - [id: 0x95fab9fc, L:/127.0.0.1:10038
  ↳ R:/127.0.0.1:57250] INBOUND DATA: streamId=21 padding=0 endStream=true
length=293
  ↳ bytes=000000001200a83010a80010a7e0a6f4d45443a3a65656538663130322d6164666662d346438352d38356
  ↳ ...

[...] DEBUG io.grpc.netty.NettyServerHandler - [id: 0x73e32666, L:/127.0.0.1:10002
  ↳ R:/127.0.0.1:57924] OUTBOUND DATA: streamId=45 padding=0 endStream=false
length=344
  ↳ bytes=0000000015312d0020a6a65656538663130322d6164666662d346438352d383565612d363031306138393
  ↳ ...
```

You can also observe the pings. Each component that receives a ping message sends a response back that contains the ack flag set to true.

```
[...] DEBUG io.grpc.netty.NettyServerHandler - [id: 0x73e32666, L:/127.0.0.1:10002
  ↳ R:/127.0.0.1:57924] OUTBOUND PING: ack=false bytes=57005
[...] DEBUG io.grpc.netty.NettyServerHandler - [id: 0x73e32666, L:/127.0.0.1:10002
  ↳ R:/127.0.0.1:57924] INBOUND PING: ack=true bytes=57005
```

Finally, you can see the typical `GO_AWAY` messages that the clients and the servers exchange when they disconnect in an organized manner.

```
[..] DEBUG io.grpc.netty.NettyServerHandler - [id: 0x95fab9fc, L:/127.0.0.1:10038]
↪- R:/127.0.0.1:57250] INBOUND GO_AWAY: lastStreamId=0 errorCode=0 length=0
↪bytes=
[..] DEBUG io.grpc.netty.NettyServerHandler - [id: 0x227a18df, L:/127.0.0.1:10042]
↪- R:/127.0.0.1:51246] OUTBOUND GO_AWAY: lastStreamId=2147483647 errorCode=0
length=13 bytes=6170705f726571756573746564
```

From the above logs you can get a pretty good idea of what happened around the moment when the connection was terminated. In particular, the absence of the ping, data and header messages may indicate that there was no activity on the channel, which may have prompted the proxy to terminate the connection. Similarly, the absence of the courtesy GO_AWAY messages may indicate that the connection was terminated abruptly.

35.10 Performance Issues

How to obtain a performant system is [extensively documented](#).

If you have followed that documentation, we can assume that:

Your database pools are sufficiently sized: check metric `db-storage.queue` and you've [correctly setup your database](#).

You have set the right settings with respect to:

- number of threads (check cpu usage)
- number of database connections (connection pool size) (`max-connections` in storage)
- high-throughput sequencer settings (`sequencer.writer.type = high-throughput`)

The database server is using SSDs and not spinning disks, and the latency to the database is low.

The database has enough memory to keep the indexes in memory (`shared_buffers`!) and is properly configured.

The number of connections to the database aligns with the available resources on the database. A database can not concurrently serve more than one request per CPU. Allocating too many connections will lead to contention and slow down the database (latency under load goes up as you queue on the db).

You are not using one of the slow DLT layers such as Fabric or Besu that are simply limited in their throughput (`sequencer.type = database`).

You have enough spare CPU capacity (cpu usage is not at 100%).

You don't have other systems competing for resources.

The max inflight transaction resource limits on the participant (`participant1.resources.set_resource_limits`) have been set carefully. The resource limits are low enough so that an application cannot overload Canton. The resource limits are high enough such that applications can submit commands at the desired target rate.

You are able to load the system fully. I.e. the load generator that you apply is submitting faster than the system can handle (i.e. you throttle using, for example, max 1000 pending commands, the latency grows linearly with num pending commands).

You have [optimized your model](#) to reduce the transaction size.

If you have done all that, you might have reached the limit of what the Canton version you are using can do. The next step is then to find out which component is creating the bottleneck. Generally, it is either one of the nodes or the database.

35.10.1 How to Measure Database Performance

To get a first impression of database performance, enable the following metrics:

Metrics containing `executor.waittime`. These metrics show the time (in millis) a db command needs to wait until Canton sends it to the db. High values indicate that the db is a bottleneck.

Metrics containing `executor.queued`. These metrics show the number of db commands waiting in a queue for being sent to the db. High values indicate that the db is a bottleneck.

Metrics containing `executor.running`. These metrics show the number of tasks currently being executed by the db. Very high values indicate that Canton is overloading the db. Very low values indicate that Canton is not fully loading the db. The number of db connections can be configured via `canton.<path-to-my-node>.storage.parameters.max-connections`.

35.10.2 How to Diagnose Slow Database Queries

If database metrics indicate that the database is a bottleneck you may want to obtain more detailed information on query performance. For that, you need to enable query cost monitoring (`canton.monitoring.log-query-cost.every = 60s`). Once you have done that, Canton will log every 60 seconds a report on query statistics:

```
2022-08-16 07:12:35,528 [slick-diexec_domain-4-7] INFO c.d.c.r.
↳DbStorage:domain=diexec_domain - Here is our list of the 15 most expensive
↳database queries for canton.db-storage.general.executor:
count=    598 mean=   13.61 ms total=   8.1 s com.digitalasset.canton.domain.
↳sequencing.sequencer.store.DbSequencerStore.saveWatermark(DbSequencerStore.
↳scala:593)
count=    598 mean=    8.82 ms total=   5.3 s com.digitalasset.canton.domain.
↳sequencing.sequencer.store.DbSequencerStore.fetchWatermark(DbSequencerStore.
↳scala:621)
count=      1 mean=   29.48 ms total=   0.0 s com.digitalasset.canton.domain.
↳sequencing.authentication.DbMemberAuthenticationStore.
↳expireNoncesAndTokens(MemberAuthenticationStore.scala:234)
count=      2 mean=    9.37 ms total=   0.0 s com.digitalasset.canton.topology.
↳store.db.DbTopologyStore.$anonfun$queryForTransactions$2(DbTopologyStore.
↳scala:387)
count=      1 mean=   18.52 ms total=   0.0 s
```

The information in here can be very useful:

`count` means how often has this query run in the last period.

`mean` means what was the average execution time of that query

`total = count * mean`

`saveWatermark(DbSequencerStore.scala:593)` is really the query with the place in the source code that is being run

Please note that the execution time of the query does not include queuing time in the connection pool. The time is really the time it took from sending to the JDBC driver to getting the result back.

Now, you do the following analysis:

if you have for example `max-connections = 4` and you log once a minute, if the total time of the queries approaches 240s, then you are obviously using up all db connections that are available.

if a single query runs for 60s, then that query might be a sequential bottleneck, as it has been running for 60s out of the 60s interval.

the mean time should also tell you roughly the db latency, as there are some cheap read queries that should run $< 1ms$. If these queries take a long time, then you know that the database has high latencies or is overloaded.

all the queries should normally take between 5-15ms. If you see queries taking consistently longer (e.g. all of them 60 - 70ms), then your database system is overloaded, queuing too many database requests on the database. You might want to increase the database resources (CPUs) or reduce the number of connections. While seeming counter intuitive, but giving too many db connections to a node will reduce the throughput, not increase it.

verify whether you might be affected by [contention on shared resources in a shared environment](#).

35.10.3 How to find the Bottleneck

In some situations, you would like to understand which component is causing a particular bottleneck. You can do that using the following technique.

35.10.3.1 Theory

In a model system with several computing stages:

Input -> Stage1 -> Stage2 -> Stage3 -> Stage4 -> Stage5 -> Output

The maximum throughput of the system is given by the minimum of the maximum throughputs of all stages. Let's assume that the max throughput is limited by Stage3 that has 100 tx/s.

Now, if you have an input source that will throttle its submission based on the number of open requests, then we know that the average latency of each transaction is going to be

latency = num-open-requests / max-throughput

The latency will grow linearly with the number of open requests. Now, as we previously defined that

throughput(Stage 3) < throughput (all other Stages)

We know that the open requests will be starting to pile up in front of Stage 3, because all other stages are processing every transaction much faster.

Therefore, if we run the system under full load with N pending requests, such that the observed latency is large compared to the zero load latency of the system, then the bottleneck is trivially observable from the trace of a command: there will be a gap in the trace of a command, where the transaction is not being processed for (observed latency - zero load latency). That gap is the sequential bottleneck.

35.10.3.2 Practical

1. Find out what the zero load latency of your system is by running a simple ping over an idle system. A ping does three end-to-end Daml transactions, so your zero load latency is just a third of the observed ping latency.
2. Run the system under full load again, including debug logging. You should be able to load the system such that the observed latency is at least an order of magnitude larger than the zero load latency.
3. Open the log files and pick a transaction in the middle of your test run:
Look for `TransactionAccepted` somewhere in the log file and pick the trace-id
Filter for the trace-id and find the command-id. Add the command-id to the filter
Hit Shift-T to see the time differences.
Find the gaps

To increase confidence, repeat this assessment on a few more transactions.

35.11 Contention

35.11.1 Why do you get contention

This section here explains you how to deal with situations where many commands are failing with errors such as:

```
LOCAL_VERDICT_LOCKED_CONTRACTS
LOCAL_VERDICT_LOCKED_KEYS
LOCAL_VERDICT_INCONSISTENT_KEY
LOCAL_VERDICT_INACTIVE_CONTRACTS
LOCAL_VERDICT_DUPLICATE_KEY
CONTRACT_NOT_FOUND
DUPLICATE_CONTRACT_KEY
```

Canton is not just a distributed system, but a distributed **racy** system where different independent actors may race for contracts or other resources. As a simple example: if you have an offer contract that can be accepted by a buyer and revoked by the seller, then the decision of the buyer to accept can race with a decision of the seller to revoke the offer.

Now, a distributed decision system with individual actors can be **accidentally racy** or **intentionally racy**. Let's explain the difference between the two:

Intentionally racy: You are putting out an offer for anyone interested on a first-come first serve basis. People might race for it and that is intended.

Accidentally racy: You turn off the traffic lights at a crossing. Suddenly, access to the shared resource (the crossing) is not managed anymore such that everyone rushes into it, blocking the entire box, making it impossible for anyone to move, leading to a complete traffic break-down.

If the system and model is intentionally racy, there is nothing you can do about the rejections. They must be there as they are the result of resolving the race for resources. But often, you will find the situation that the model is accidentally racy, which can be fixed by changing the model slightly. In many cases, contention arises due to contract-keys being fetched and updated. The issue is then that the transaction is built in phase 1, looking at the contract key state at that time. The validation / conflict detection happens then in phase 3. If any other transaction changed that particular key in the time between phase 1 and phase 3, the transaction will fail.

Whether you get `INACTIVE_CONTRACTS`, `LOCKED_CONTRACT` or `CONTRACT_NOT_FOUND` just depends on timing of the competing transaction. `LOCKED` means: there is a transaction about to change this resource, but we have not yet received the final verdict on it.

35.11.2 How To Change Your Model To Avoid Undesired Contention

Now, you can resolve such accidental raciness by introducing order into the race. As an example, you let individuals submit `request contracts` and you add one delegated party that receives these requests and orders and performs their application to a shared resource (through delegation). As an example, if you have an `AccountIdGenerator`:

```
template AccountIdGenerator
  next : Integer
  ...
where
  choice NextAccount : (ContractId AccountId, ContractId AccountIdGenerator)
  do
    a <- create this with next = next + 1
    b <- create AccountId with accountId = next
    return (a,b)
```

This `AccountIdGenerator` contract will be very racy. However, you can just add a:

```
template GetAccountIdRequest
```

and then have a single application consume these requests and generate ids. That single application knows whether it has already spent the existing `AccountIdGenerator` contract. Of course, it would make sense to support a list of requests in the choice `NextAccount` such that many `AccountIds` are created at once, as otherwise, the throughput of account allocation would be limited.

This is just a simple example, but should be sufficient to illustrate the issue and the solution idea.

35.11.3 How To Find Contention

In a distributed application, where different systems such as ledger clients, Triggers, Nanobots, Ingestion Applications, and the like submit transactions, it may not be easy to understand where the contention is coming from. Here is a recipe that can be used on the Canton level:

1. Ensure that you have turned on Detailed API Logging with Debug logs.
2. Run your system / tests until you have collected enough information / rejections.
3. Open the log files and search for one of the rejections, i.e. search for `LOCKED`.
4. Filter by the trace-id of this rejection. Determine the command-id using the `rosetta stone` log entry. Add the command-id to the filter.
5. Now, find the `ApiRequestLogger` log entry of the `CommandSubmissionService`. This log entry contains the entire command that the application has submitted (if you turned on the detailed api logging). I.e. the `exercise choice` that caused the contention.
6. Then, go back to the rejection (i.e. the one with `LOCKED`). This rejection will contain a `ResourceInfo`, referring to the key / contract that caused the rejection. The `ResourceInfo` will contain the key that caused the failure.

Using the above recipe, you determine the choice and which key in that particular choice created the problem. This should be sufficient to find the problematic parts in the model.

35.12 Use Bisection to Narrow Down the Root Cause

In this section an alternative approach is outlined that could help you if the guidelines in the previous sections were insufficient to resolve the problem. To apply that approach, you do not need a deep understanding of Canton. It is not only suitable to investigate problems inside of Canton, it also helps to discover problems coming from the environment.

The approach is best explained with an example. Suppose you have developed a Canton deployment and successfully tested it on your local machine. After moving it to the distributed test environment, it is showing some problems. So you have two Canton deployments, a local one and distributed one, one of them works correctly, the other one is broken.

You notice the following differences between the two deployments:

- The local deployment runs all nodes in a single process. The distributed deployment runs nodes in different processes.
- The local deployment runs all nodes on the same machine. The distributed deployment runs nodes on different machines.
- Only the distributed deployment has TLS enabled.
- Only the distributed deployment has high-availability enabled.
- The distributed deployment runs in a docker container (e.g. by using a cloud environment). The local deployment does not use docker.

To better understand which of the differences is causing the problem, you setup a new deployment that has **only half of the differences**. That could mean, you setup a new deployment with the following characteristics:

- It runs nodes in **different processes** (like the distributed deployment)
- It runs nodes on the same machine (like the test deployment).
- It has TLS **enabled**.
- It has high availability disabled.
- It does not use docker.

For the sake of reference, let's call it Deployment 3. Now you rerun the test. If the test succeeds (as for the local deployment), you know that the problem in the distributed deployment is caused by the network, by high-availability, or by docker. If the test fails (as for the distributed deployment), you know that the problem is caused by running several processes, by using TLS or by both. For the sake of the illustration, let's assume the test succeeds.

To further narrow down the root cause, you setup yet another deployment that is in the middle between Deployment 3 (which was successful) and the distributed deployment (which was failing). That could mean:

- It runs nodes in different processes.
- It runs nodes on **different** machines (like the distributed deployment).
- It has TLS enabled.
- It has high availability disabled.
- It does not use docker.

Let's call it Deployment 4. Again, you rerun the test. If the test succeeds, you know that the problem in the distributed deployment is caused by high-availability or by docker. If the test fails, you know that the problem is caused by some combination of running nodes in different processes, on different machines and having TLS enabled. Let's assume that the test fails.

To further narrow down the root cause, try to set up the simplest possible deployment that still has the problem. That could mean:

You simplify your test, e.g., **run a ping** instead of a complex workflow. It runs **only two nodes** (because you are aiming for a minimal example).

The two nodes run **in different processes on different machines** (because that seemed to be the root cause).

TLS is **disabled** (because that seemed not to trigger the problem).

High availability is disabled.

It does not use docker.

Let's call it Deployment 5 . If the test fails on Deployment 5 , you have a minimal example to reproduce the problem. You know that the problem is caused by running two nodes on different machines. The problem is independent of your Daml workflow, occurs already with two nodes and without enabling TLS. If the test succeeds on Deployment 5 , you have not yet understood the root cause. In that case, you need to do yet another iteration with a deployment in the middle between Deployment 4 and Deployment 5 .

The following guidelines are helpful to make this approach successful:

Try to keep the list of differences between successful and failing deployment **as complete as possible**. If the root cause is not on your list, you can't find it. Differences can come from configuration, Daml models, ledger applications, deployment (in process, network, docker, kubernetes,), hardware, operating system.

Always **aim at the middle** between the successful and failing deployment to learn the most with every new deployment you create and test. That is the fastest path to the root cause.

Don't make assumptions up front of which difference may or may not cause the problem. For example, if you are making the assumption that the problem is not caused by TLS, you may save one iteration, if you are right. But you will take a long detour, if you are wrong.

Do not assume that the problem is caused by a single difference between the two deployments. It could very well be that a **combination of differences** is needed to **reproduce the problem**.

Chapter 36

Support Checklist

So that we can successfully provide support, and to ensure that you can troubleshoot the system efficiently on your own, we recommend that you follow the checklist below to ensure that you have access to all the necessary information and tools to resolve an issue and that you have established the necessary administrative access to your production system.

The [troubleshooting guide](#) goes into detail on how to use the information and tools provided in this checklist.

Please note that the below list is used to prepare for the worst-case scenario and generally refers to good practices for being prepared for any kind of issue.

36.1 Remote Console Access

Admin Console Access

You are able to connect to each Canton node in your setup using a [remote console](#).

Check Node Health

Using the admin console, you can run `node.health.status` to check the health of the node.

Download the Health Dump

Using the admin console, you can run `node.health.dump()` to download a [health dump](#) of the node. Note that for versions prior to 2.9, you might need to add a `timeout=10.minutes` argument to the command.

- Confirm that you can download the health dump.
- Confirm that you can upload the health dump to a support ticket.

Smoke Test

Using the admin console on a participant, you can ping the participant to run an end-to-end check: `participant.health.ping(participant, id="READY-FOR-PRODUCTION")`

Ledger API Access

Using the console on a participant, you can access the Ledger API for further troubleshooting. For this, you need to be able to enable the flag `canton.features.enable-testing-commands = yes` on your remote console.

- Confirm access by successfully running the command `participant.ledger_api.acs.of_party(participant.id.adminParty)`.

36.2 Logging

Access to Readable Logs

You are able to download the native Canton logs from your production system. This is relevant as the logs are highly structured and contain information that is sometimes omitted by third-party log aggregators.

- The logs can be read [using Inav](#).
- They include the trace-id (`tid:`)
- They include at least the log-level INFO.
- Confirm that you can upload the log files to a support ticket.

Note that you can set up Canton to create rolling log files which are included in the health dump. Both the standard and the default Canton JSON logging format are fine. If you need custom loggers, please add them as an extension to the built-in [logback.xml](#).

Attention to WARN and ERROR logs

You are monitoring the logs for WARN and ERROR messages. Canton logs WARN on degradations and ERROR on fatal failures. There should never be an ERROR in the logs emitted by the Canton loggers.

Finding Commands in the Logs

You are able to find the commands that were submitted to Canton in the logs. Verify that you can find the previous ping in your logs looking for `READY-FOR-PRODUCTION` (which was the argument passed as `id`). You should see several log entries mentioning `Phase 1 started: Submitting commands for interpretation, one for each Daml transaction of the ping command`.

Log File Permanence

You have a strategy in place to ensure that the logs are not lost when the node is restarted.

- Restart your node and confirm that the logs of the ping command are still available.

Log Level Change

You are able to change the log level of the Canton loggers using the remote console command `node.health.set_log_level(Level.DEBUG)`.

- Confirm that the log level changes to DEBUG and change it back again.

Command Id / Trace Id in Application Logs

Your applications provide a trace-id or at least the command-id in their logs that can be correlated with the Canton logs. Please consult our [guide on how to add end-to-end tracing](#) to your application.

- Verify that you can find the trace-id or command-id in your application logs and correlate it with the Canton logs.

36.3 Metrics

Access to Metrics

You are able to extract key metrics from your production system, in particular the JVM metrics.

36.4 Configuration and Patching

Access to Configuration Files

You are able to edit and change the configuration files of your production system if necessary.

Patch Release Process

You have a well-defined procedure for applying patch releases to your production system.

36.5 Database Access

Access to the Database

You have a well-defined procedure for database access to run queries if necessary or access database statistics.

Ability to Snapshot

You are able to take a snapshot of the database and restore it to a different environment for troubleshooting and recovery procedure testing.

Established and Tested Backup Procedure

In worst case, you are able to restore the system to a working state using your automated backups.

Chapter 37

Error Codes

37.1 Overview

The goal of all error messages in Daml is to enable users, developers, and operators to act independently on the encountered errors, either manually or with an automated process.

Most errors are a result of request processing. Each error is logged and returned to the user as a failed gRPC response containing the status code, an optional status message and optional metadata. We further enhance this by providing:

- improved consistency of the returned errors across API endpoints
- richer error payload format with clearly distinguished machine-readable parts to facilitate automated error handling strategies
- complete inventory of all error codes with an explanation, suggested resolution and other useful information

37.2 Glossary

Error Represents an occurrence of a failure. Consists of:

- an *error code id*,
- a [gRPC status code](#) (determined by its error category),
- an *error category*,
- a *correlation id*,
- a human readable message,
- and optional additional metadata.

You can think of it as an instantiation of an error code.

Error Code Represents a class of failures. Identified by its error code id (we may use *error code* and *error code id* interchangeably in this document). Belongs to a single error category.

Error Category A broad categorization of error codes that you can base your error handling strategies on. Maps to exactly one [gRPC status code](#). We recommend dealing with errors based on their error category. However, if the error category alone is too generic you can act on a particular error code.

Correlation Id A value that allows the user to clearly identify the request, such that the operator can lookup any log information associated with this error. We use the request's submission id for correlation id.

37.3 Anatomy of an Error

Errors returned to users contain a [gRPC status code](#), a description, and additional machine-readable information represented in the [rich gRPC error model](#).

37.3.1 Error Description

We use the [standard gRPC description](#) that additionally adheres to our custom message format:

```
<ERROR_CODE_ID>(<CATEGORY_ID>,<CORRELATION_ID_PREFIX>):<HUMAN_READABLE_MESSAGE>
```

The constituent parts are:

`<ERROR_CODE_ID>` - a unique non-empty string containing at most 63 characters: upper-case letters, underscores or digits. Identifies corresponding error code id.

`<CATEGORY_ID>` - a small integer identifying the corresponding error category.

`<CORRELATION_ID_PREFIX>` - a string aimed at identifying originating request. Absence of one is indicated by value 0. If present, it is the first 8 characters of the corresponding request's submission id. Full correlation id can be found in error's additional machine readable information (see [Additional Machine-Readable Information](#)).

`:` - a colon serves as a separator for the machine and human readable parts of the error description.

`<HUMAN_READABLE_MESSAGE>` - a message targeted at a human reader. Should never be parsed by applications, as the description might change in future releases to improve clarity.

In a concrete example an error description might look like this:

```
TRANSACTION_NOT_FOUND(11,12345): Transaction not found, or not visible.
```

37.3.2 Additional Machine-Readable Information

We use following error details:

A mandatory `com.google.rpc.ErrorInfo` containing *error code id*.

A mandatory `com.google.rpc.RequestInfo` containing (not-truncated) correlation id (or 0 if correlation id is not available).

An optional `com.google.rpc.RetryInfo` containing retry interval with milliseconds resolution.

An optional `com.google.rpc.ResourceInfo` containing information about the resource the failure is based on. Any request that fails due to some well-defined resource issues (such as contract, contract key, package, party, template, sync domain, etc.) contains these. Particular resources are implementation-specific and vary across ledger implementations.

Many errors will include more information, but there is no guarantee that additional information will be preserved across versions.

37.3.3 Prevent Security Leaks in Error Codes

For any error that could leak information to an attacker, the system returns an error message via the API that contains no valuable information. The log file contains the full error message.

37.3.4 Work With Error Codes

This example shows how a user can extract the relevant error information:

```
object SampleClientSide {

  import com.google.rpc.ResourceInfo
  import com.google.rpc.{ErrorInfo, RequestInfo, RetryInfo}
  import io.grpc.StatusRuntimeException
  import scala.jdk.CollectionConverters._

  def example(): Unit = {
    try {
      DummyServer.serviceEndpointDummy()
    } catch {
      case e: StatusRuntimeException =>
        // Converting to a status object.
        val status = io.grpc.protobuf.StatusProto.fromThrowable(e)

        // Extracting gRPC status code.
        assert(status.getCode == io.grpc.Status.Code.ABORTED.value())
        assert(status.getCode == 10)

        // Extracting error message, both
        // machine oriented part: "MY_ERROR_CODE_ID(2,full-cor):",
        // and human oriented part: "A user oriented message".
        assert(status.getMessage == "MY_ERROR_CODE_ID(2,full-cor): A user
        oriented message")

        // Getting all the details
        val rawDetails: Seq[com.google.protobuf.Any] = status.getDetailsList.
        asScala.toSeq

        // Extracting error code id, error category id and optionally additional
        metadata.
        assert {
          rawDetails.collectFirst {
            case any if any.is(classOf[ErrorInfo]) =>
              val v = any.unpack(classOf[ErrorInfo])
              assert(v.getReason == "MY_ERROR_CODE_ID")
              assert(v.getMetadataMap.asScala.toMap == Map("category" -> "2", "foo
              -> "bar"))
            }.isDefined
          }

          // Extracting full correlation id, if present.
          assert {
            rawDetails.collectFirst {
              case any if any.is(classOf[RequestInfo]) =>
                val v = any.unpack(classOf[RequestInfo])

```

(continues on next page)

(continued from previous page)

```

        assert(v.getRequestId == "full-correlation-id-123456790")
      }.isDefined
    }

    // Extracting retry information if the error is retryable.
    assert {
      rawDetails.collectFirst {
        case any if any.is(classOf[RetryInfo]) =>
          val v = any.unpack(classOf[RetryInfo])
          assert(v.getRetryDelay.getSeconds == 123, v.getRetryDelay.
↪getSeconds)
          assert(v.getRetryDelay.getNanos == 456 * 1000 * 1000, v.
↪getRetryDelay.getNanos)
      }.isDefined
    }

    // Extracting resource if the error pertains to some well defined
↪resource.
    assert {
      rawDetails.collectFirst {
        case any if any.is(classOf[ResourceInfo]) =>
          val v = any.unpack(classOf[ResourceInfo])
          assert(v.getResourceType == "CONTRACT_ID")
          assert(v.getResourceName == "someContractId")
      }.isDefined
    }
  }
}

```

37.4 Error Codes In Canton Operations

Almost all errors and warnings that can be generated by a Canton-based system are annotated with error codes of the form **SOMETHING_NOT_SO_GOOD_HAPPENED(x,c)**. The upper case string with underscores denotes the unique error id. The parentheses include key additional information. The id together with the extra information is referred to as `error-code`. The **x** represents the [ErrorCategory](#) used to classify the error, and the **c** represents the first 8 characters of the correlation id associated with this request, or 0 if no correlation id is given.

The majority of errors in Canton-based systems are a result of request processing and are logged and returned to the user as described above. In other cases, errors occur due to background processes (i.e. network connection issues/transaction confirmation processing). Such errors are only logged.

Generally, we use the following log levels on the server:

INFO to log user errors where the error leads to a failure of the request but the system remains healthy.

WARN to log degradations of the system or point out unusual behavior.

ERROR to log internal errors where the system does not behave properly and immediate attention is required.

On the client side, failures are considered to be errors and logged as such.

37.5 Error Categories

The error categories allow you to group errors such that application logic can be built to automatically deal with errors and decide whether to retry a request or escalate to the operator.

A full list of error categories is documented [here](#).

37.6 Machine Readable Information

Every error on the API is constructed to allow automated and manual error handling. First, the error category maps to exactly one gRPC status code. Second, every [error description](#) (of the corresponding `StatusRuntimeException.Status`) starts with the error information (**SOMETHING_NOT_SO_GOOD_HAPPENED(CN,x)**), separated from a human readable description by a colon (:). The rest of the description is targeted to humans and should never be parsed by applications, as the description might change in future releases to improve clarity.

In addition to the status code and the description, the [gRPC rich error model](#) is used to convey additional, machine-readable information to the application.

Therefore, to support automatic error processing, an application may:

- parse the error information from the beginning of the description to obtain the error-id, the error category and the component.
- use the gRPC-code to get the set of possible error categories.
- if present, use the `ResourceInfo` included as `Status.details`. Any request that fails due to some well-defined resource issues (contract, contract key, package, party, template, sync domain) will contain these, calling out on what resource the failure is based on.
- use the `RetryInfo` to determine the recommended retry interval (or make this decision based on the category / gRPC code).
- use the `RequestInfo.id` as the [correlation-id](#), included as `Status.details`.
- use the `ErrorInfo.reason` as error-id and `ErrorInfo.metadata("category")` as error category, included as `Status.details`.

All this information is included in errors that are generated by components under our control and included as `Status.details`. As with Daml error codes described above, many errors include more information, but there is no guarantee that additional information will be preserved across versions.

Generally, automated error handling can be done on any level (e.g. load balancer using gRPC status codes, application using `ErrorCategory` or human reacting to error IDs). In most cases it is advisable to deal with errors on a per-category basis and deal with error IDs in very specific situations which are application-dependent. For example, a command failure with the message `CONTRACT_NOT_FOUND` may be an application failure in case the given application is the only actor on the contracts, whereas a `CONTRACT_NOT_FOUND` message is to be expected in a case where multiple independent actors operate on the ledger state.

37.7 Example

If an application submits a Daml transaction that exceeds the size limits enforced on a sync domain, the command will be rejected. Using the logs of one of our test cases, the participant node will log the following message:

```
2022-04-26 11:37:54,584 [GracefulRejectsIntegrationTestDefault-env-execution-
↳context-30] INFO c.d.c.p.p.TransactionProcessingSteps:participant=participant1/
↳domain=da tid:13617c1bda402e54e016a6a17637cb20 - SEQUENCER_REQUEST_FAILED(2,
↳13617c1b): Failed to send command err-context:
↳{location=TransactionProcessingSteps.scala:449, sendError=RequestInvalid(Batch
↳size (85134 bytes) is exceeding maximum size (27000 bytes) for domain
↳da::12201253c344...)}
```

The machine-readable part of the error message appears as `SEQUENCER_REQUEST_FAILED(2, 13617c1b)`, mentioning the error id `SEQUENCER_REQUEST_FAILED`, the category `ContentionOnSharedResources` with id=2, and the correlation identifier `13617c1b`. Please note that there is no guarantee on the name of the logger that is emitting the given error, as this name is internal and subject to change. The human-readable part of the log message should not be parsed, as we might subsequently improve the text.

The client will receive the error information as a Grpc error:

```
2022-04-26 11:37:54,923 [ScalaTest-run-running-
↳GracefulRejectsIntegrationTestDefault] ERROR c.d.c.i.
↳EnterpriseEnvironmentDefinition$$$anon$3 - Request failed for participant1.
  GrpcRequestRefusedByServer: ABORTED/SEQUENCER_REQUEST_FAILED(2,13617c1b):
↳Failed to send command
  Request: SubmitAndWaitTransactionTree(actAs = participant1::1220baa5cd30...,
↳commandId = '', workflowId = '', submissionId = '', deduplicationPeriod =
↳None(), ledgerId = 'participant1', commands= ...)
  CorrelationId: 13617c1bda402e54e016a6a17637cb20
  RetryIn: 1 second
  Context: HashMap(participant -> participant1, test ->
↳GracefulRejectsIntegrationTestDefault, domain -> da, sendError ->
↳RequestInvalid(Batch size (85134 bytes) is exceeding maximum size (27000 bytes)
↳for domain da::12201253c344...), definite_answer -> true)
```

Note that the second log is created by Daml tooling that prints the Grpc Status into the log files during tests. The actual Grpc error would be received by the application and would not be logged by the participant node in the given form.

37.8 Error Categories Inventory

The error categories allow you to group errors such that application logic can be built in a sensible way to automatically deal with errors and decide whether to retry a request or escalate to the operator.

37.8.1 TransientServerFailure

Category id: 1

gRPC status code: UNAVAILABLE

Default log level: INFO

Description: One of the services required to process the request was not available.

Resolution: Expectation: transient failure that should be handled by retrying the request with appropriate backoff.

Retry strategy: Retry quickly in load balancer.

37.8.2 ContentionOnSharedResources

Category id: 2

gRPC status code: ABORTED

Default log level: INFO

Description: The request could not be processed due to shared processing resources (e.g. locks or rate limits that replenish quickly) being occupied. If the resource is known (i.e. locked contract), it will be included as a resource info. (Not known resource contentions are e.g. overloaded networks where we just observe timeouts, but can't pin-point the cause).

Resolution: Expectation: this is processing-flow level contention that should be handled by retrying the request with appropriate backoff.

Retry strategy: Retry quickly (indefinitely or limited), but do not retry in load balancer.

37.8.3 DeadlineExceededRequestStateUnknown

Category id: 3

gRPC status code: DEADLINE_EXCEEDED

Default log level: INFO

Description: The request might not have been processed, as its deadline expired before its completion was signalled. Note that for requests that change the state of the system, this error may be returned even if the request has completed successfully. Note that known and well-defined timeouts are signalled as `[[ContentionOnSharedResources]]`, while this category indicates that the state of the request is unknown.

Resolution: Expectation: the deadline might have been exceeded due to transient resource congestion or due to a timeout in the request processing pipeline being too low. The transient errors might be solved by the application retrying. The non-transient errors will require operator intervention to change the timeouts.

Retry strategy: Retry for a limited number of times with deduplication.

37.8.4 SystemInternalAssumptionViolated

Category id: 4

gRPC status code: INTERNAL

Default log level: ERROR

Description: Request processing failed due to a violation of system internal invariants. This error is exposed on the API with grpc-status INTERNAL without any details for security reasons

Resolution: Expectation: this is due to a bug in the implementation or data corruption in the systems databases. Resolution will require operator intervention, and potentially vendor support.

Retry strategy: Retry after operator intervention.

37.8.5 AuthInterceptorInvalidAuthenticationCredentials

Category id: 6

gRPC status code: UNAUTHENTICATED

Default log level: WARN

Description: The request does not have valid authentication credentials for the operation. This error is exposed on the API with grpc-status UNAUTHENTICATED without any details for security reasons

Resolution: Expectation: this is an application bug, application misconfiguration or ledger-level misconfiguration. Resolution requires application and/or ledger operator intervention.

Retry strategy: Retry after application operator intervention.

37.8.6 InsufficientPermission

Category id: 7

gRPC status code: PERMISSION_DENIED

Default log level: WARN

Description: The caller does not have permission to execute the specified operation. This error is exposed on the API with grpc-status PERMISSION_DENIED without any details for security reasons

Resolution: Expectation: this is an application bug or application misconfiguration. Resolution requires application operator intervention.

Retry strategy: Retry after application operator intervention.

37.8.7 SecurityAlert

Category id: 5

gRPC status code: INVALID_ARGUMENT

Default log level: WARN

Description: A potential attack or a faulty peer component has been detected. This error is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Resolution: Expectation: this can be a severe issue that requires operator attention or intervention, and potentially vendor support. It means that the system has detected invalid information that can be attributed to either faulty or malicious manipulation of data coming from a peer source.

Retry strategy: Errors in this category are non-retryable.

37.8.8 InvalidIndependentOfSystemState

Category id: 8

gRPC status code: INVALID_ARGUMENT

Default log level: INFO

Description: The request is invalid independent of the state of the system.

Resolution: Expectation: this is an application bug or ledger-level misconfiguration (e.g. request size limits). Resolution requires application and/or ledger operator intervention.

Retry strategy: Retry after application operator intervention.

37.8.9 InvalidGivenCurrentSystemStateOther

Category id: 9

gRPC status code: FAILED_PRECONDITION

Default log level: INFO

Description: The mutable state of the system does not satisfy the preconditions required to execute the request. We consider the whole Daml ledger including ledger config, parties, packages, users and command deduplication to be mutable system state. Thus all Daml interpretation errors are reported as this error or one of its specializations.

Resolution: ALREADY_EXISTS and NOT_FOUND are special cases for the existence and non-existence of well-defined entities within the system state; e.g., a .dalf package, contracts ids, contract keys, or a transaction at an offset. OUT_OF_RANGE is a special case for reading past a range. Violations of the Daml ledger model always result in these kinds of errors. Expectation: this is due to application-level bugs, misconfiguration or contention on application-visible resources; and might be resolved by retrying later, or after changing the state of the system. Handling these errors requires an application-specific strategy and/or operator intervention.

Retry strategy: Retry after application operator intervention.

37.8.10 InvalidGivenCurrentSystemStateResourceExists

Category id: 10

gRPC status code: ALREADY_EXISTS

Default log level: INFO

Description: Special type of InvalidGivenCurrentSystemState referring to a well-defined resource.

Resolution: Same as [[InvalidGivenCurrentSystemStateOther]].

Retry strategy: Inspect resource failure and retry after resource failure has been resolved (depends on type of resource and application).

37.8.11 InvalidGivenCurrentSystemStateResourceMissing

Category id: 11

gRPC status code: NOT_FOUND

Default log level: INFO

Description: Special type of InvalidGivenCurrentSystemState referring to a well-defined resource.

Resolution: Same as [[InvalidGivenCurrentSystemStateOther]].

Retry strategy: Inspect resource failure and retry after resource failure has been resolved (depends on type of resource and application).

37.8.12 InvalidGivenCurrentSystemStateSeekAfterEnd

Category id: 12

gRPC status code: OUT_OF_RANGE

Default log level: INFO

Description: This error is only used by the Ledger API server in connection with invalid offsets.

Resolution: Expectation: this error is only used by the Ledger API server in connection with invalid offsets.

Retry strategy: Retry after application operator intervention.

37.8.13 BackgroundProcessDegradationWarning

Category id: 13

gRPC status code: N/A

Default log level: WARN

Description: This error category is used internally to signal to the system operator an internal degradation.

Resolution: Inspect details of the specific error for more information.

Retry strategy: Not an API error, therefore not retryable.

37.8.14 InternalUnsupportedOperation

Category id: 14

gRPC status code: UNIMPLEMENTED

Default log level: ERROR

Description: This error category is used to signal that an unimplemented code-path has been triggered by a client or participant operator request. This error is exposed on the API with grpc-status UNIMPLEMENTED without any details for security reasons

Resolution: This error is caused by a ledger-level misconfiguration or by an implementation bug. Resolution requires participant operator intervention.

Retry strategy: Errors in this category are non-retryable.

37.9 Error Codes Inventory - Daml

37.9.1 1. ParticipantErrorGroup

37.9.2 1.1. ParticipantErrorGroup / CommonErrors

Common errors raised in Daml services and components.

37.9.2.1 REQUEST_TIME_OUT

Explanation: This rejection is given when a request processing status is not known and a time-out is reached.

Category: DeadlineExceededRequestStateUnknown

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status DEADLINE_EXCEEDED including a detailed error message.

Resolution: Retry for transient problems. If non-transient contact the operator as the time-out limit might be too short.

37.9.2.2 SERVER_IS_SHUTTING_DOWN

Explanation: This rejection is given when the participant server is shutting down.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Resolution: Contact the participant operator.

37.9.2.3 SERVICE_INTERNAL_ERROR

Explanation: This error occurs if one of the services encountered an unexpected exception.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Resolution: Contact support.

37.9.2.4 SERVICE_NOT_RUNNING

Explanation: This rejection is given when the requested service has already been closed.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Resolution: Retry re-submitting the request. If the error persists, contact the participant operator.

37.9.2.5 UNSUPPORTED_OPERATION

Explanation: This error category is used to signal that an unimplemented code-path has been triggered by a client or participant operator request.

Category: InternalUnsupportedOperation

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status UNIMPLEMENTED without any details for security reasons.

Resolution: This error is caused by a participant node misconfiguration or by an implementation bug. Resolution requires participant operator intervention.

37.9.3 1.2. ParticipantErrorGroup / IndexErrors

Errors raised by the Participant Index persistence layer.

37.9.4 1.2.1. ParticipantErrorGroup / IndexErrors / DatabaseErrors

37.9.4.1 INDEX_DB_SQL_NON_TRANSIENT_ERROR

Explanation: This error occurs if a non-transient error arises when executing a query against the index database.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Resolution: Contact the participant operator.

37.9.4.2 INDEX_DB_SQL_TRANSIENT_ERROR

Explanation: This error occurs if a transient error arises when executing a query against the index database.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Resolution: Re-submit the request.

37.9.5 1.3. ParticipantErrorGroup / LedgerApiErrors

Errors raised by or forwarded by the Ledger API.

37.9.5.1 LEDGER_API_INTERNAL_ERROR

Explanation: This error occurs if there was an unexpected error in the Ledger API.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Resolution: Contact support.

37.9.6 1.3.1. ParticipantErrorGroup / LedgerApiErrors / AdminServices

Errors raised by Ledger API admin services.

37.9.6.1 CONFIGURATION_ENTRY_REJECTED

Explanation: This rejection is given when a new configuration is rejected.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Fetch newest configuration and/or retry.

37.9.7 1.3.1.1. ParticipantErrorGroup / LedgerApiErrors / AdminServices / IdentityProviderConfigServiceErrorGroup

37.9.7.1 IDP_CONFIG_ALREADY_EXISTS

Explanation: There already exists an identity provider configuration with the same identity provider id.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Resolution: Check that you are connecting to the right participant node and the identity provider id is spelled correctly, or use an identity provider that already exists.

37.9.7.2 IDP_CONFIG_ISSUER_ALREADY_EXISTS

Explanation: There already exists an identity provider configuration with the same issuer.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Resolution: Check that you are connecting to the right participant node and the identity provider id is spelled correctly, or use an identity provider that already exists.

37.9.7.3 IDP_CONFIG_NOT_FOUND

Explanation: The identity provider config referred to by the request was not found.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Check that you are connecting to the right participant node and the identity provider config is spelled correctly, or create the configuration.

37.9.7.4 INVALID_IDENTITY_PROVIDER_UPDATE_REQUEST

Explanation: There was an attempt to update an identity provider config using an invalid update request.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the error details for specific information on what made the request invalid. Retry with an adjusted update request.

37.9.8 1.3.1.2. ParticipantErrorGroup / LedgerApiErrors / AdminServices / PartyManagementServiceErrorGroup

37.9.8.1 CONCURRENT_PARTY_DETAILS_UPDATE_DETECTED

Explanation: Concurrent updates to a party can be controlled by supplying an update request with a resource version (this is optional). A party's resource version can be obtained by reading the party on the Ledger API. There was attempt to update a party using a stale resource version, indicating that a different process had updated the party earlier.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Resolution: Read this party again to obtain its most recent state and in particular its most recent resource version. Use the obtained information to build and send a new update request.

37.9.8.2 INVALID_PARTY_DETAILS_UPDATE_REQUEST

Explanation: There was an attempt to update a party using an invalid update request.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the error details for specific information on what made the request invalid. Retry with an adjusted update request.

37.9.8.3 PARTY_NOT_FOUND

Explanation: The party referred to by the request was not found.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Check that you are connecting to the right participant node and that the party is spelled correctly.

37.9.9 1.3.1.3. ParticipantErrorGroup / LedgerApiErrors / AdminServices / UserManagementServiceErrorGroup

37.9.9.1 CONCURRENT_USER_UPDATE_DETECTED

Explanation: Concurrent updates to a user can be controlled by supplying an update request with a resource version (this is optional). A user's resource version can be obtained by reading the user on the Ledger API. There was attempt to update a user using a stale resource version, indicating that a different process had updated the user earlier.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Resolution: Read this user again to obtain its most recent state and in particular its most recent resource version. Use the obtained information to build and send a new update request.

37.9.9.2 INVALID_USER_UPDATE_REQUEST

Explanation: There was an attempt to update a user using an invalid update request.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the error details for specific information on what made the request invalid. Retry with an adjusted update request.

37.9.9.3 TOO_MANY_USER_RIGHTS

Explanation: A user can have only a limited number of user rights. There was an attempt to create a user with too many rights or grant too many rights to a user.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Retry with a smaller number of rights or delete some of the already existing rights of this user. Contact the participant operator if the limit is too low.

37.9.9.4 USER_ALREADY_EXISTS

Explanation: There already exists a user with the same user-id.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Resolution: Check that you are connecting to the right participant node and the user-id is spelled correctly, or use the user that already exists.

37.9.9.5 USER_NOT_FOUND

Explanation: The user referred to by the request was not found.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Check that you are connecting to the right participant node and the user-id is spelled correctly, if yes, create the user.

37.9.10 1.3.2. ParticipantErrorGroup / LedgerApiErrors / AuthorizationChecks

Authentication and authorization errors.

37.9.10.1 INTERNAL_AUTHORIZATION_ERROR

Explanation: An internal system authorization error occurred.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Resolution: Contact the participant operator.

37.9.10.2 PERMISSION_DENIED

Explanation: This rejection is given if the supplied authorization token is not sufficient for the intended command. The exact reason is logged on the participant, but not given to the user for security reasons.

Category: InsufficientPermission

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status PERMISSION_DENIED without any details for security reasons.

Resolution: Inspect your command and your token or ask your participant operator for an explanation why this command failed.

37.9.10.3 STALE_STREAM_AUTHORIZATION

Explanation: The stream was aborted because the authenticated user's rights changed, and the user might thus no longer be authorized to this stream.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Resolution: The application should automatically retry fetching the stream. It will either succeed, or fail with an explicit denial of authentication or permission.

37.9.10.4 UNAUTHENTICATED

Explanation: This rejection is given if the submitted command does not contain a JWT token on a participant enforcing JWT authentication.

Category: AuthInterceptorInvalidAuthenticationCredentials

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status UNAUTHENTICATED without any details for security reasons.

Resolution: Ask your participant operator to provide you with an appropriate JWT token.

37.9.11 1.3.3. ParticipantErrorGroup / LedgerApiErrors / CommandExecution

Errors raised during the command execution phase of the command submission evaluation.

37.9.12 1.3.3.1. ParticipantErrorGroup / LedgerApiErrors / CommandExecution / Interpreter

Errors raised during the command interpretation phase of the command submission evaluation.

37.9.12.1 CONTRACT_DOES_NOT_IMPLEMENT_INTERFACE

Explanation: This error occurs when you try to coerce/use a contract via an interface that it does not implement.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Ensure the contract you are calling does implement the interface you are using to do so. Avoid writing LF/low-level interface implementation classes manually.

37.9.12.2 CONTRACT_DOES_NOT_IMPLEMENT_REQUIRING_INTERFACE

Explanation: This error occurs when you try to create/use a contract that does not implement the requiring interfaces of some other interface that it does implement.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Ensure you implement all required interfaces correctly, and avoid writing LF/low-level interface implementation classes manually.

37.9.12.3 CONTRACT_ID_COMPARABILITY

Explanation: This error occurs when you attempt to compare a global and local contract ID of the same discriminator.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Avoid constructing contract IDs manually.

37.9.12.4 CONTRACT_ID_IN_CONTRACT_KEY

Explanation: This error occurs when a contract key contains a contract ID, which is illegal for hashing reasons.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Ensure your contracts key field cannot contain a contract ID.

37.9.12.5 CONTRACT_NOT_ACTIVE

Explanation: This error occurs if an exercise or fetch happens on a transaction-locally consumed contract.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: This error indicates an application error.

37.9.12.6 CREATE_EMPTY_CONTRACT_KEY_MAINTAINERS

Explanation: This error occurs when you try to create a contract that has a key, but with empty maintainers.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Check the definition of the contract key's maintainers, and ensure this list won't be empty given your creation arguments.

37.9.12.7 DAML_AUTHORIZATION_ERROR

Explanation: This error occurs if a Daml transaction fails due to an authorization error. An authorization means that the Daml transaction computed a different set of required submitters than you have provided during the submission as actAs parties.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: This error type occurs if there is an application error.

37.9.12.8 DISCLOSED_CONTRACT_KEY_HASHING_ERROR

Explanation: This error occurs if a user attempts to provide a key hash for a disclosed contract which we have already cached to be different.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Ensure the contract ID and contract payload you have provided in your disclosed contract is correct.

37.9.12.9 FETCH_EMPTY_CONTRACT_KEY_MAINTAINERS

Explanation: This error occurs when you try to fetch a contract by key, but that key would have empty maintainers.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Check the definition of the contract key's maintainers, and ensure this list won't be empty given the contract key you are fetching.

37.9.12.10 NON_COMPARABLE_VALUES

Explanation: This error occurs when you attempt to compare two values of different types using the built-in comparison types.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Avoid using the low level comparison build, and instead use the Eq class.

37.9.12.11 TEMPLATE_PRECONDITION_VIOLATED

Explanation: This error occurs when a contract's pre-condition (the ensure clause) is violated on contract creation.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Ensure the contract argument you are passing into your create doesn't violate the conditions of the contract.

37.9.12.12 UNHANDLED_EXCEPTION

Explanation: This error occurs when a user throws an error and does not catch it with try-catch.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Either your error handling in a choice body is insufficient, or you are using a contract incorrectly.

37.9.12.13 VALUE_NESTING

Explanation: This error occurs when you nest values too deeply.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Restructure your code and reduce value nesting.

37.9.12.14 `WRONGLY_TYPED_CONTRACT`

Explanation: This error occurs when you try to fetch/use a contract in some way with a contract ID that doesn't match the template type on the ledger.

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Resolution: Ensure the contract IDs you are using are of the type we expect on the ledger. Avoid unsafely coercing contract IDs.

37.9.13 1.3.3.1.1. `ParticipantErrorGroup / LedgerApiErrors / CommandExecution / Interpreter / LookupErrors`

Errors raised in lookups during the command interpretation phase.

37.9.13.1 `CONTRACT_KEY_NOT_FOUND`

Explanation: This error occurs if the Daml engine interpreter cannot resolve a contract key to an active contract. This can be caused by either the contract key not being known to the participant, or not being known to the submitting parties or the contract representing an already archived key.

Category: `InvalidGivenCurrentSystemStateResourceMissing`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status NOT_FOUND` including a detailed error message.

Resolution: This error type occurs if there is contention on a contract.

37.9.14 1.3.3.2. `ParticipantErrorGroup / LedgerApiErrors / CommandExecution / Pre-processing`

Errors raised during command conversion to the internal data representation.

37.9.14.1 `COMMAND_PREPROCESSING_FAILED`

Explanation: This error occurs if a command fails during interpreter pre-processing.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status INVALID_ARGUMENT` including a detailed error message.

Resolution: Inspect error details and correct your application.

37.9.15 1.3.4. ParticipantErrorGroup / LedgerApiErrors / ConsistencyErrors

Potential consistency errors raised due to race conditions during command submission or returned as submission rejections by the backing ledger.

37.9.15.1 CONTRACT_NOT_FOUND

Explanation: This error occurs if the Daml engine can not find a referenced contract. This can be caused by either the contract not being known to the participant, or not being known to the submitting parties or already being archived.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: This error type occurs if there is contention on a contract.

37.9.15.2 DUPLICATE_COMMAND

Explanation: A command with the given command id has already been successfully processed.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Resolution: The correct resolution depends on the use case. If the error received pertains to a submission retried due to a timeout, do nothing, as the previous command has already been accepted. If the intent is to submit a new command, re-submit using a distinct command id.

37.9.15.3 DUPLICATE_CONTRACT_KEY

Explanation: This error signals that within the transaction we got to a point where two contracts with the same key were active.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Resolution: This error indicates an application error.

37.9.15.4 INCONSISTENT_CONTRACT_KEY

Explanation: An input contract key was re-assigned to a different contract by a concurrent transaction submission.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Retry the transaction submission.

37.9.15.5 SUBMISSION_ALREADY_IN_FLIGHT

Explanation: Another command submission with the same change ID (application ID, command ID, actAs) is already being processed.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Resolution: Listen to the command completion stream until a completion for the in-flight command submission is published. Alternatively, resubmit the command. If the in-flight submission has finished successfully by then, this will return more detailed information about the earlier one. If the in-flight submission has failed by then, the resubmission will attempt to record the new transaction on the ledger.

37.9.16 1.3.5. ParticipantErrorGroup / LedgerApiErrors / PackageServiceError

Errors raised by the Package Management Service on package uploads.

37.9.16.1 DAR_NOT_SELF_CONSISTENT

Explanation: This error indicates that the uploaded Dar is broken because it is missing internal dependencies.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Contact the supplier of the Dar.

37.9.16.2 DAR_VALIDATION_ERROR

Explanation: This error indicates that the validation of the uploaded dar failed.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the error message and contact support.

37.9.16.3 PACKAGE_SERVICE_INTERNAL_ERROR

Explanation: This error indicates an internal issue within the package service.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Resolution: Inspect the error message and contact support.

37.9.17 1.3.5.1. ParticipantErrorGroup / LedgerApiErrors / PackageServiceError / Reading

Package parsing errors raised during package upload.

37.9.17.1 INVALID_DAR

Explanation: This error indicates that the supplied dar file was invalid.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the error message for details and contact support.

37.9.17.2 INVALID_ZIP_ENTRY

Explanation: This error indicates that the supplied zipped dar file was invalid.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the error message for details and contact support.

37.9.17.3 ZIP_BOMB

Explanation: This error indicates that the supplied zipped dar is regarded as zip-bomb.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the dar and contact support.

37.9.18 1.3.6. ParticipantErrorGroup / LedgerApiErrors / RequestValidation

Validation errors raised when evaluating requests in the Ledger API.

37.9.18.1 INVALID_ARGUMENT

Explanation: This error is emitted when a submitted ledger API command contains an invalid argument.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the reason given and correct your application.

37.9.18.2 INVALID_DEDUPLICATION_PERIOD

Explanation: This error is emitted when a submitted ledger API command specifies an invalid deduplication period.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Inspect the error message, adjust the value of the deduplication period or ask the participant operator to increase the maximum deduplication period.

37.9.18.3 INVALID_FIELD

Explanation: This error is emitted when a submitted ledger API command contains a field value that cannot be understood.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the reason given and correct your application.

37.9.18.4 LEDGER_ID_MISMATCH

Explanation: Every ledger API command contains a ledger-id which is verified against the running ledger. This error indicates that the provided ledger-id does not match the expected one.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Ensure that your application is correctly configured to use the correct ledger.

37.9.18.5 MISSING_FIELD

Explanation: This error is emitted when a mandatory field is not set in a submitted ledger API command.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Inspect the reason given and correct your application.

37.9.18.6 NON_HEXADECIMAL_OFFSET

Explanation: The supplied offset could not be converted to a binary offset.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Resolution: Ensure the offset is specified as a hexadecimal string.

37.9.18.7 OFFSET_AFTER_LEDGER_END

Explanation: This rejection is given when a read request uses an offset beyond the current ledger end.

Category: InvalidGivenCurrentSystemStateSeekAfterEnd

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status OUT_OF_RANGE including a detailed error message.

Resolution: Use an offset that is before the ledger end.

37.9.18.8 OFFSET_OUT_OF_RANGE

Explanation: This rejection is given when a read request uses an offset invalid in the requests' context.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Inspect the error message and use a valid offset.

37.9.18.9 PARTICIPANT_PRUNED_DATA_ACCESSED

Explanation: This rejection is given when a read request tries to access pruned data.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Resolution: Use an offset that is after the pruning offset.

37.9.19 1.3.6.1. ParticipantErrorGroup / LedgerApiErrors / RequestValidation / Not-Found

37.9.19.1 LEDGER_CONFIGURATION_NOT_FOUND

Explanation: The ledger configuration could not be retrieved. This could happen due to incomplete initialization of the participant or due to an internal system error.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Contact the participant operator.

37.9.19.2 PACKAGE_NOT_FOUND

Explanation: This rejection is given when a read request tries to access a package which does not exist on the ledger.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Use a package id pertaining to a package existing on the ledger.

37.9.19.3 TEMPLATES_OR_INTERFACES_NOT_FOUND

Explanation: The queried template or interface ids do not exist.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Use valid template or interface ids in your query or ask the participant operator to upload the package containing the necessary interfaces/templates.

37.9.19.4 TRANSACTION_NOT_FOUND

Explanation: The transaction does not exist or the requesting set of parties are not authorized to fetch it.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Check the transaction id and verify that the requested transaction is visible to the requesting parties.

37.9.20 1.3.7. ParticipantErrorGroup / LedgerApiErrors / WriteServiceRejections

Generic submission rejection errors returned by the backing ledger's write service.

37.9.20.1 DISPUTED

Deprecation: Corresponds to transaction submission rejections that are not produced anymore. Since: 1.18.0

Explanation: An invalid transaction submission was not detected by the participant.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Resolution: Contact support.

37.9.20.2 OUT_OF_QUOTA

Deprecation: Corresponds to transaction submission rejections that are not produced anymore. Since: 1.18.0

Explanation: The Participant node did not have sufficient resource quota to submit the transaction.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Resolution: Inspect the error message and retry after after correcting the underlying issue.

37.9.20.3 PARTY_NOT_KNOWN_ON_LEDGER

Explanation: One or more informee parties have not been allocated.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Resolution: Check that all the informee party identifiers are correct, allocate all the informee parties, request their allocation or wait for them to be allocated before retrying the transaction submission.

37.10 Error Codes Inventory - Canton

37.10.1 1. GrpcErrors

37.10.1.1 ABORTED_DUE_TO_SHUTDOWN

Explanation: This error is returned when processing of the request was aborted due to the node shutting down.

Resolution: Retry the request against an active and available node.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [ABORTED_DUE_TO_SHUTDOWN](#)

37.10.2 2. AuthorizationChecksErrors

37.10.2.1 ACCESS_TOKEN_EXPIRED

Explanation: This rejection is given when a valid JWT token used for some period of time expires.

Resolution: Ask your participant operator or IDP provider to give you an appropriate JWT token.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [ACCESS_TOKEN_EXPIRED](#)

37.10.2.2 INTERNAL_AUTHORIZATION_ERROR

Explanation: An internal system authorization error occurred.

Resolution: Contact the participant operator.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INTERNAL_AUTHORIZATION_ERROR](#)

37.10.2.3 INVALID_TOKEN

Explanation: This error is emitted when a submitted ledger API command contains an invalid token.

Resolution: Inspect the reason given and correct your application.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_TOKEN](#)

37.10.2.4 PERMISSION_DENIED

Explanation: This rejection is given if the supplied authorization token is not sufficient for the intended command. The exact reason is logged on the participant, but not given to the user for security reasons.

Resolution: Inspect your command and your token or ask your participant operator for an explanation why this command failed.

Category: InsufficientPermission

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status PERMISSION_DENIED without any details for security reasons.

Scaladocs: [PERMISSION_DENIED](#)

37.10.2.5 STALE_STREAM_AUTHORIZATION

Explanation: The stream was aborted because the authenticated user's rights changed, and the user might thus no longer be authorized to this stream.

Resolution: The application should automatically retry fetching the stream. It will either succeed, or fail with an explicit denial of authentication or permission.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [STALE_STREAM_AUTHORIZATION](#)

37.10.2.6 UNAUTHENTICATED

Explanation: This rejection is given if the submitted command does not contain a JWT token on a participant enforcing JWT authentication.

Resolution: Ask your participant operator or IDP provider to give you an appropriate JWT token.

Category: `AuthInterceptorInvalidAuthenticationCredentials`

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status UNAUTHENTICATED without any details for security reasons.

Scaladocs: [UNAUTHENTICATED](#)

37.10.3 3. ParticipantErrorGroup

37.10.4 3.1. Errors

37.10.4.1 ACS_COMMITMENT_INTERNAL_ERROR

Explanation: This error indicates that there was an internal error within the ACS commitment processing.

Resolution: Inspect error message for details.

Category: `SystemInternalAssumptionViolated`

Conveyance: This error is logged with log-level ERROR on the server side.

Scaladocs: [ACS_COMMITMENT_INTERNAL_ERROR](#)

37.10.5 3.1.1. MismatchError

37.10.5.1 ACS_COMMITMENT_ALARM

Explanation: The participant has detected that another node is behaving maliciously.

Resolution: Contact support.

Category: `SecurityAlert`

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [ACS_COMMITMENT_ALARM](#)

37.10.5.2 ACS_COMMITMENT_MISMATCH

Explanation: This error indicates that a remote participant has sent a commitment over an ACS for a period which does not match the local commitment. This error occurs if a remote participant has manually changed contracts using repair, or due to byzantine behavior, or due to malfunction of the system. The consequence is that the ledger is forked, and some commands that should pass will not.

Resolution: Please contact the other participant in order to check the cause of the mismatch. Either repair the store of this participant or of the counterparty.

Category: `SecurityAlert`

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [ACS_COMMITMENT_MISMATCH](#)

37.10.5.3 ACS_MISMATCH_NO_SHARED_CONTRACTS

Explanation: This error indicates that a remote participant has sent a commitment over an ACS for a period, while this participant does not think that there is a shared contract state. This error occurs if a remote participant has manually changed contracts using repair, or due to byzantine behavior, or due to malfunction of the system. The consequence is that the ledger is forked, and some commands that should pass will not.

Resolution: Please contact the other participant in order to check the cause of the mismatch. Either repair the store of this participant or of the counterparty.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [ACS_MISMATCH_NO_SHARED_CONTRACTS](#)

37.10.6 3.1.2. DegradationError

37.10.6.1 ACS_COMMITMENT_DEGRADATION

Explanation: The participant has detected that ACS computation is taking too long and trying to catch up.

Resolution: Catch up mode is enabled and the participant should recover on its own.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [ACS_COMMITMENT_DEGRADATION](#)

37.10.6.2 ACS_COMMITMENT_DEGRADATION_WITH_INEFFECTIVE_CONFIG

Explanation: The participant is configured to engage catchup mode, however configuration is invalid to have any effect

Resolution: Please update catchup mode to have a catchUpIntervalSkip higher than 1

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [ACS_COMMITMENT_DEGRADATION_WITH_INEFFECTIVE_CONFIG](#)

37.10.7 3.2. LedgerApiErrorGroup

37.10.8 3.2.1. CommandExecutionErrors

37.10.8.1 FAILED_TO_DETERMINE_LEDGER_TIME

Explanation: This error occurs if the participant fails to determine the max ledger time of the used contracts. Most likely, this means that one of the contracts is not active anymore which can happen under contention. It can also happen with contract keys.

Resolution: Retry the transaction submission.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [FAILED_TO_DETERMINE_LEDGER_TIME](#)

37.10.8.2 INTERPRETATION_TIME_EXCEEDED

Explanation: This error occurs when the interpretation of a command exceeded the time limit, defined as the maximum time that can be assigned by the ledger when it starts processing the command. It corresponds to the time assigned upon submission by the participant (the ledger time) + a tolerance defined by the `ledgerTimeToRecordTimeTolerance` ledger configuration parameter. Reasons for exceeding this limit can vary: the participant may be under high load, the command interpretation may be very complex, or even run into an infinite loop due to a mistake in the Daml code.

Resolution: Due to the halting problem, we cannot determine whether the interpretation will eventually complete. As a developer: inspect your code for possible non-terminating loops or consider reducing its complexity. As an operator: check and possibly update the resources allocated to the system, as well as the time-related configuration parameters (see `Time on Daml Ledgers` in the `Daml Ledger Model Concepts` doc section and the `set_ledger_time_record_time_tolerance` console command).

Category: `ContentionOnSharedResources`

Conveyance: This error is logged with log-level `WARN` on the server side and exposed on the API with `grpc-status ABORTED` including a detailed error message.

Scaladocs: [INTERPRETATION_TIME_EXCEEDED](#)

37.10.9 3.2.1.1. Package

37.10.9.1 ALLOWED_LANGUAGE_VERSIONS

Explanation: This error indicates that the uploaded DAR is based on an unsupported language version.

Resolution: Use a DAR compiled with a language version that this participant supports.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level `INFO` on the server side and exposed on the API with `grpc-status INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [ALLOWED_LANGUAGE_VERSIONS](#)

37.10.9.2 PACKAGE_VALIDATION_FAILED

Explanation: This error occurs if a package referred to by a command fails validation. This should not happen as packages are validated when being uploaded.

Resolution: Contact support.

Category: `SecurityAlert`

Conveyance: This error is logged with log-level `WARN` on the server side. It is exposed on the API with `grpc-status INVALID_ARGUMENT` without any details for security reasons.

Scaladocs: [PACKAGE_VALIDATION_FAILED](#)

37.10.10 3.2.1.2. Preprocessing

37.10.10.1 `COMMAND_PREPROCESSING_FAILED`

Explanation: This error occurs if a command fails during interpreter pre-processing.

Resolution: Inspect error details and correct your application.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status `INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [COMMAND_PREPROCESSING_FAILED](#)

37.10.11 3.2.1.3. Interpreter

37.10.11.1 `CONTRACT_DOES_NOT_IMPLEMENT_INTERFACE`

Explanation: This error occurs when you try to coerce/use a contract via an interface that it does not implement.

Resolution: Ensure the contract you are calling does implement the interface you are using to do so. Avoid writing LF/low-level interface implementation classes manually.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status `INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [CONTRACT_DOES_NOT_IMPLEMENT_INTERFACE](#)

37.10.11.2 `CONTRACT_DOES_NOT_IMPLEMENT_REQUIRING_INTERFACE`

Explanation: This error occurs when you try to create/use a contract that does not implement the requiring interfaces of some other interface that it does implement.

Resolution: Ensure you implement all required interfaces correctly, and avoid writing LF/low-level interface implementation classes manually.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status `INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [CONTRACT_DOES_NOT_IMPLEMENT_REQUIRING_INTERFACE](#)

37.10.11.3 `CONTRACT_ID_COMPARABILITY`

Explanation: This error occurs when you attempt to compare a global and local contract ID of the same discriminator.

Resolution: Avoid constructing contract IDs manually.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status `INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [CONTRACT_ID_COMPARABILITY](#)

37.10.11.4 CONTRACT_ID_IN_CONTRACT_KEY

Explanation: This error occurs when a contract key contains a contract ID, which is illegal for hashing reasons.

Resolution: Ensure your contracts key field cannot contain a contract ID.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [CONTRACT_ID_IN_CONTRACT_KEY](#)

37.10.11.5 CONTRACT_NOT_ACTIVE

Explanation: This error occurs if an exercise or fetch happens on a transaction-locally consumed contract.

Resolution: This error indicates an application error.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [CONTRACT_NOT_ACTIVE](#)

37.10.11.6 CREATE_EMPTY_CONTRACT_KEY_MAINTAINERS

Explanation: This error occurs when you try to create a contract that has a key, but with empty maintainers.

Resolution: Check the definition of the contract key's maintainers, and ensure this list won't be empty given your creation arguments.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [CREATE_EMPTY_CONTRACT_KEY_MAINTAINERS](#)

37.10.11.7 DAML_AUTHORIZATION_ERROR

Explanation: This error occurs if a Daml transaction fails due to an authorization error. An authorization means that the Daml transaction computed a different set of required submitters than you have provided during the submission as actAs parties.

Resolution: This error type occurs if there is an application error.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DAML_AUTHORIZATION_ERROR](#)

37.10.11.8 DAML_INTERPRETATION_ERROR

Explanation: This error occurs if a Daml transaction fails during interpretation.

Resolution: This error type occurs if there is an application error.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DAML_INTERPRETATION_ERROR](#)

37.10.11.9 DAML_INTERPRETER_INVALID_ARGUMENT

Explanation: This error occurs if a Daml transaction fails during interpretation due to an invalid argument.

Resolution: This error type occurs if there is an application error.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DAML_INTERPRETER_INVALID_ARGUMENT](#)

37.10.11.10 DISALLOWED_INTERFACE_EXERCISE

Explanation: Exercising an LF 1.15 interface implemented by an LF 1.17 (or newer) template is disallowed since 2.10.1

Resolution: Use LF 1.17 for the interface definition.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DISALLOWED_INTERFACE_EXERCISE](#)

37.10.11.11 DISCLOSED_CONTRACT_KEY_HASHING_ERROR

Explanation: This error occurs if a user attempts to provide a key hash for a disclosed contract which we have already cached to be different.

Resolution: Ensure the contract ID and contract payload you have provided in your disclosed contract is correct.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DISCLOSED_CONTRACT_KEY_HASHING_ERROR](#)

37.10.11.12 `FETCH_EMPTY_CONTRACT_KEY_MAINTAINERS`

Explanation: This error occurs when you try to fetch a contract by key, but that key would have empty maintainers.

Resolution: Check the definition of the contract key's maintainers, and ensure this list won't be empty given the contract key you are fetching.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [FETCH_EMPTY_CONTRACT_KEY_MAINTAINERS](#)

37.10.11.13 `INTERPRETATION_DEV_ERROR`

Explanation: This error is a catch-all for errors thrown by in-development features, and should never be thrown in production.

Resolution: See the error message for details of the specific in-development feature error. If this is production, avoid using development features.

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [INTERPRETATION_DEV_ERROR](#)

37.10.11.14 `INTERPRETATION_USER_ERROR`

Explanation: This error occurs when a user calls `abort` or `error` on an LF version before native exceptions were introduced.

Resolution: Either remove the call to `abort`, `error` or perhaps `assert`, or ensure you are exercising your contract choice as the author expects.

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [INTERPRETATION_USER_ERROR](#)

37.10.11.15 `NON_COMPARABLE_VALUES`

Explanation: This error occurs when you attempt to compare two values of different types using the built-in comparison types.

Resolution: Avoid using the low level comparison build, and instead use the `Eq` class.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [NON_COMPARABLE_VALUES](#)

37.10.11.16 TEMPLATE_PRECONDITION_VIOLATED

Explanation: This error occurs when a contract's pre-condition (the ensure clause) is violated on contract creation.

Resolution: Ensure the contract argument you are passing into your create doesn't violate the conditions of the contract.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [TEMPLATE_PRECONDITION_VIOLATED](#)

37.10.11.17 UNHANDLED_EXCEPTION

Explanation: This error occurs when a user throws an error and does not catch it with try-catch.

Resolution: Either your error handling in a choice body is insufficient, or you are using a contract incorrectly.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [UNHANDLED_EXCEPTION](#)

37.10.11.18 VALUE_NESTING

Explanation: This error occurs when you nest values too deeply.

Resolution: Restructure your code and reduce value nesting.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [VALUE_NESTING](#)

37.10.11.19 WRONGLY_TYPED_CONTRACT

Explanation: This error occurs when you try to fetch/use a contract in some way with a contract ID that doesn't match the template type on the ledger.

Resolution: Ensure the contract IDs you are using are of the type we expect on the ledger. Avoid unsafely coercing contract IDs.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [WRONGLY_TYPED_CONTRACT](#)

37.10.12 3.2.1.3.1. LookupErrors

37.10.12.1 CONTRACT_KEY_NOT_FOUND

Explanation: This error occurs if the Daml engine interpreter cannot resolve a contract key to an active contract. This can be caused by either the contract key not being known to the participant, or not being known to the submitting parties or the contract representing an already archived key.

Resolution: This error type occurs if there is contention on a contract.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [CONTRACT_KEY_NOT_FOUND](#)

37.10.13 3.2.1.3.2. UpgradeError

37.10.13.1 CONTRACT_NOT_UPGRADABLE

Explanation: An attempt was made to upgrade a template compiled with a daml language version before 1.17

Resolution: If possible archive this contract and re-create it with a template compiled with daml 1.17 or above

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [CONTRACT_NOT_UPGRADABLE](#)

37.10.13.2 INTERPRETATION_UPGRADE_ERROR_DOWNGRADE_DROP_DEFINED_FIELD

Explanation: An optional contract field with a value of Some may not be dropped during downgrading

Resolution: There is data that is newer than the implementation it is being used it, and thus is not compatible. Ensure new data (i.e. those with additional fields as Some) is only used with new choices

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INTERPRETATION_UPGRADE_ERROR_DOWNGRADE_DROP_DEFINED_FIELD](#)

37.10.13.3 INTERPRETATION_UPGRADE_ERROR_DOWNGRADE_FAILED

Explanation: An optional contract field with a value of Some may not be dropped during downgrading

Resolution: There is data that is newer than the implementation using it, and thus is not compatible. Ensure new data (i.e. those with additional fields as Some) is only used with new/compatible choices

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INTERPRETATION_UPGRADE_ERROR_DOWNGRADE_FAILED](#)

37.10.13.4 INTERPRETATION_UPGRADE_ERROR_VALIDATION_FAILED

Explanation: Validation fails when trying to upgrade the contract

Resolution: Verify that neither the signatories, nor the observers, nor the contract key, nor the key's maintainers have changed

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INTERPRETATION_UPGRADE_ERROR_VALIDATION_FAILED](#)

37.10.13.5 INTERPRETATION_UPGRADE_ERROR_VIEW_MISMATCH

Explanation: View mismatch when trying to upgrade the contract

Resolution: Verify that the interface views of the contract have not changed

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INTERPRETATION_UPGRADE_ERROR_VIEW_MISMATCH](#)

37.10.14 3.2.2. AdminServicesErrorGroup

37.10.15 3.2.2.1. PartyManagementServiceErrors

37.10.15.1 CONCURRENT_PARTY_DETAILS_UPDATE_DETECTED

Explanation: Concurrent updates to a party can be controlled by supplying an update request with a resource version (this is optional). A party's resource version can be obtained by reading the party on the Ledger API. There was attempt to update a party using a stale resource version, indicating that a different process had updated the party earlier.

Resolution: Read this party again to obtain its most recent state and in particular its most recent resource version. Use the obtained information to build and send a new update request.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [CONCURRENT_PARTY_DETAILS_UPDATE_DETECTED](#)

37.10.15.2 INTERNAL_PARTY_RECORD_ALREADY_EXISTS

Explanation: Each on-ledger party known to this participant node can have a participant's local metadata assigned to it. The local information about a party referred to by this request was found when it should have been not found.

Resolution: This error can indicate a problem with the server's storage or implementation.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INTERNAL_PARTY_RECORD_ALREADY_EXISTS](#)

37.10.15.3 INTERNAL_PARTY_RECORD_NOT_FOUND

Explanation: Each on-ledger party known to this participant node can have a participant's local metadata assigned to it. The local information about a party referred to by this request was not found when it should have been found.

Resolution: This error can indicate a problem with the server's storage or implementation.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INTERNAL_PARTY_RECORD_NOT_FOUND](#)

37.10.15.4 INVALID_PARTY_DETAILS_UPDATE_REQUEST

Explanation: There was an attempt to update a party using an invalid update request.

Resolution: Inspect the error details for specific information on what made the request invalid. Retry with an adjusted update request.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_PARTY_DETAILS_UPDATE_REQUEST](#)

37.10.15.5 MAX_PARTY_DETAILS_ANNOTATIONS_SIZE_EXCEEDED

Explanation: A party can have at most 256kb worth of annotations in total measured in number of bytes in UTF-8 encoding. There was an attempt to allocate or update a party such that this limit would have been exceeded.

Resolution: Retry with fewer annotations or delete some of the party's existing annotations.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [MAX_PARTY_DETAILS_ANNOTATIONS_SIZE_EXCEEDED](#)

37.10.15.6 PARTY_NOT_FOUND

Explanation: The party referred to by the request was not found.

Resolution: Check that you are connecting to the right participant node and that the party is spelled correctly.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [INTERNALLY_INVALID_KEY](#)

37.10.18.3 PACKAGE_UPLOAD_REJECTED

Explanation: This rejection is given when a package upload is rejected.

Resolution: Refer to the detailed message of the received error.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PACKAGE_UPLOAD_REJECTED](#)

37.10.19 3.2.4. ConsistencyErrors

37.10.19.1 CONTRACT_NOT_FOUND

Explanation: This error occurs if the Daml engine can not find a referenced contract. This can be caused by either the contract not being known to the participant, or not being known to the submitting parties or already being archived.

Resolution: This error type occurs if there is contention on a contract.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [CONTRACT_NOT_FOUND](#)

37.10.19.2 DISCLOSED_CONTRACT_INVALID

Explanation: This error occurs if the disclosed payload or metadata of one of the contracts does not match the actual payload or metadata of the contract.

Resolution: Re-submit the command using valid disclosed contract payload and metadata.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DISCLOSED_CONTRACT_INVALID](#)

37.10.19.3 DUPLICATE_COMMAND

Explanation: A command with the given command id has already been successfully processed.

Resolution: The correct resolution depends on the use case. If the error received pertains to a submission retried due to a timeout, do nothing, as the previous command has already been accepted. If the intent is to submit a new command, re-submit using a distinct command id.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [DUPLICATE_COMMAND](#)

37.10.19.4 DUPLICATE_CONTRACT_KEY

Explanation: This error signals that within the transaction we got to a point where two contracts with the same key were active.

Resolution: This error indicates an application error.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [DUPLICATE_CONTRACT_KEY](#)

37.10.19.5 INCONSISTENT

Explanation: At least one input has been altered by a concurrent transaction submission.

Resolution: The correct resolution depends on the business flow, for example it may be possible to proceed without an archived contract as an input, or the transaction submission may be retried to load the up-to-date value of a contract key.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INCONSISTENT](#)

37.10.19.6 INCONSISTENT_CONTRACTS

Explanation: An input contract has been archived by a concurrent transaction submission.

Resolution: The correct resolution depends on the business flow, for example it may be possible to proceed without the archived contract as an input, or a different contract could be used.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INCONSISTENT_CONTRACTS](#)

37.10.19.7 INCONSISTENT_CONTRACT_KEY

Explanation: An input contract key was re-assigned to a different contract by a concurrent transaction submission.

Resolution: Retry the transaction submission.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INCONSISTENT_CONTRACT_KEY](#)

37.10.19.8 INVALID_LEDGER_TIME

Explanation: The ledger time of the submission violated some constraint on the ledger time.

Resolution: Retry the transaction submission.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INVALID_LEDGER_TIME](#)

37.10.19.9 SUBMISSION_ALREADY_IN_FLIGHT

Explanation: Another command submission with the same change ID (application ID, command ID, actAs) is already being processed.

Resolution: Listen to the command completion stream until a completion for the in-flight command submission is published. Alternatively, resubmit the command. If the in-flight submission has finished successfully by then, this will return more detailed information about the earlier one. If the in-flight submission has failed by then, the resubmission will attempt to record the new transaction on the ledger.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [SUBMISSION_ALREADY_IN_FLIGHT](#)

37.10.20 3.2.5. PackageServiceErrors

37.10.20.1 DAR_NOT_SELF_CONSISTENT

Explanation: This error indicates that the uploaded Dar is broken because it is missing internal dependencies.

Resolution: Contact the supplier of the Dar.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DAR_NOT_SELF_CONSISTENT](#)

37.10.20.2 DAR_NOT_VALID_UPGRADE

Explanation: This error indicates that the uploaded Dar is invalid because it doesn't upgrade the packages it claims to upgrade.

Resolution: Contact the supplier of the Dar.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DAR_NOT_VALID_UPGRADE](#)

37.10.20.3 DAR_VALIDATION_ERROR

Explanation: This error indicates that the validation of the uploaded dar failed.

Resolution: Inspect the error message and contact support.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DAR_VALIDATION_ERROR](#)

37.10.20.4 KNOWN_DAR_VERSION

Explanation: This error indicates that the Dar upload failed upgrade checks because a package with the same version and package name has been previously uploaded.

Resolution: Inspect the error message and contact support.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [KNOWN_DAR_VERSION](#)

37.10.20.5 PACKAGE_SERVICE_INTERNAL_ERROR

Explanation: This error indicates an internal issue within the package service.

Resolution: Inspect the error message and contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [PACKAGE_SERVICE_INTERNAL_ERROR](#)

37.10.20.6 SHUTDOWN_INTERRUPTED_PACKAGE_VETTING

Explanation: Package vetting has been aborted because the participant is shutting down.

Resolution: Re-submit the vetting request when the participant node is available again.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SHUTDOWN_INTERRUPTED_PACKAGE_VETTING](#)

37.10.21 3.2.5.1. Reading

37.10.21.1 DAR_PARSE_ERROR

Explanation: This error indicates that the content of the Dar file could not be parsed successfully.

Resolution: Inspect the error message and contact support.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DAR_PARSE_ERROR](#)

37.10.21.2 INVALID_DAR

Explanation: This error indicates that the supplied dar file was invalid.

Resolution: Inspect the error message for details and contact support.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_DAR](#)

37.10.21.3 INVALID_DAR_FILE_NAME

Explanation: This error indicates that the supplied dar file name did not meet the requirements to be stored in the persistence store.

Resolution: Inspect error message for details and change the file name accordingly

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_DAR_FILE_NAME](#)

37.10.21.4 INVALID_LEGACY_DAR

Explanation: This error indicates that the supplied zipped dar is an unsupported legacy Dar.

Resolution: Please use a more recent dar version.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_LEGACY_DAR](#)

37.10.21.5 INVALID_ZIP_ENTRY

Explanation: This error indicates that the supplied zipped dar file was invalid.

Resolution: Inspect the error message for details and contact support.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_ZIP_ENTRY](#)

37.10.21.6 ZIP_BOMB

Explanation: This error indicates that the supplied zipped dar is regarded as zip-bomb.

Resolution: Inspect the dar and contact support.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [ZIP_BOMB](#)

37.10.22 3.2.6. WriteServiceRejectionErrors

37.10.22.1 DISPUTED

Explanation: An invalid transaction submission was not detected by the participant.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [DISPUTED](#)

37.10.22.2 OUT_OF_QUOTA

Explanation: The Participant node did not have sufficient resource quota to submit the transaction.

Resolution: Inspect the error message and retry after after correcting the underlying issue.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [OUT_OF_QUOTA](#)

37.10.22.3 PARTY_NOT_KNOWN_ON_LEDGER

Explanation: One or more informee parties have not been allocated.

Resolution: Check that all the informee party identifiers are correct, allocate all the informee parties, request their allocation or wait for them to be allocated before retrying the transaction submission.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [PARTY_NOT_KNOWN_ON_LEDGER](#)

37.10.22.4 SUBMITTER_CANNOT_ACT_VIA_PARTICIPANT

Explanation: A submitting party is not authorized to act through the participant.

Resolution: Contact the participant operator or re-submit with an authorized party.

Category: InsufficientPermission

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status PERMISSION_DENIED without any details for security reasons.

Scaladocs: [SUBMITTER_CANNOT_ACT_VIA_PARTICIPANT](#)

37.10.22.5 SUBMITTING_PARTY_NOT_KNOWN_ON_LEDGER

Explanation: The submitting party has not been allocated.

Resolution: Check that the party identifier is correct, allocate the submitting party, request its allocation or wait for it to be allocated before retrying the transaction submission.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [SUBMITTING_PARTY_NOT_KNOWN_ON_LEDGER](#)

37.10.23 3.2.6.1. Internal

37.10.23.1 INTERNALLY_DUPLICATE_KEYS

Explanation: The participant didn't detect an attempt by the transaction submission to use the same key for two active contracts.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INTERNALLY_DUPLICATE_KEYS](#)

37.10.23.2 INTERNALLY_INCONSISTENT_KEYS

Explanation: The participant didn't detect an inconsistent key usage in the transaction. Within the transaction, an exercise, fetch or lookupByKey failed because the mapping of key->contract ID was inconsistent with earlier actions.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INTERNALLY_INCONSISTENT_KEYS](#)

37.10.24 3.2.7. RequestValidationErrors

37.10.24.1 INVALID_ARGUMENT

Explanation: This error is emitted when a submitted ledger API command contains an invalid argument.

Resolution: Inspect the reason given and correct your application.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_ARGUMENT](#)

37.10.24.2 INVALID_DEDUPLICATION_PERIOD

Explanation: This error is emitted when a submitted ledger API command specifies an invalid deduplication period.

Resolution: Inspect the error message, adjust the value of the deduplication period or ask the participant operator to increase the maximum deduplication period.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INVALID_DEDUPLICATION_PERIOD](#)

37.10.24.3 INVALID_FIELD

Explanation: This error is emitted when a submitted ledger API command contains a field value that cannot be understood.

Resolution: Inspect the reason given and correct your application.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_FIELD](#)

37.10.24.4 LEDGER_ID_MISMATCH

Explanation: Every ledger API command contains a ledger-id which is verified against the running ledger. This error indicates that the provided ledger-id does not match the expected one.

Resolution: Ensure that your application is correctly configured to use the correct ledger.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [LEDGER_ID_MISMATCH](#)

37.10.24.5 MISSING_FIELD

Explanation: This error is emitted when a mandatory field is not set in a submitted ledger API command.

Resolution: Inspect the reason given and correct your application.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [MISSING_FIELD](#)

37.10.24.6 NON_HEXADECIMAL_OFFSET

Explanation: The supplied offset could not be converted to a binary offset.

Resolution: Ensure the offset is specified as a hexadecimal string.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [NON_HEXADECIMAL_OFFSET](#)

37.10.24.7 OFFSET_AFTER_LEDGER_END

Explanation: This rejection is given when a read request uses an offset beyond the current ledger end.

Resolution: Use an offset that is before the ledger end.

Category: InvalidGivenCurrentSystemStateSeekAfterEnd

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status OUT_OF_RANGE including a detailed error message.

Scaladocs: [OFFSET_AFTER_LEDGER_END](#)

37.10.24.8 OFFSET_OUT_OF_RANGE

Explanation: This rejection is given when a read request uses an offset invalid in the requests' context.

Resolution: Inspect the error message and use a valid offset.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [OFFSET_OUT_OF_RANGE](#)

37.10.24.9 PARTICIPANT_PRUNED_DATA_ACCESSED

Explanation: This rejection is given when a read request tries to access pruned data.

Resolution: Use an offset that is after the pruning offset.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PARTICIPANT_PRUNED_DATA_ACCESSED](#)

37.10.25 3.2.7.1. NotFound

37.10.25.1 LEDGER_CONFIGURATION_NOT_FOUND

Explanation: The ledger configuration could not be retrieved. This could happen due to incomplete initialization of the participant or due to an internal system error.

Resolution: Contact the participant operator.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [LEDGER_CONFIGURATION_NOT_FOUND](#)

37.10.25.2 NO_TEMPLATES_FOR_PACKAGE_NAME_AND_QUALIFIED_NAME

Explanation: The queried type reference for the specified package name and template qualified-name does not reference any template uploaded on this participant

Resolution: Use a template qualified-name referencing already uploaded template-ids or ask the participant operator to upload the necessary packages.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [NO_TEMPLATES_FOR_PACKAGE_NAME_AND_QUALIFIED_NAME](#)

37.10.25.3 PACKAGE_NAMES_NOT_FOUND

Explanation: The queried package names do not match packages uploaded on this participant.

Resolution: Use valid package names or ask the participant operator to upload the necessary packages.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [PACKAGE_NAMES_NOT_FOUND](#)

37.10.25.4 PACKAGE_NOT_FOUND

Explanation: This rejection is given when a read request tries to access a package which does not exist on the ledger.

Resolution: Use a package id pertaining to a package existing on the ledger.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [PACKAGE_NOT_FOUND](#)

37.10.25.5 TEMPLATES_OR_INTERFACES_NOT_FOUND

Explanation: The queried template or interface ids do not exist.

Resolution: Use valid template or interface ids in your query or ask the participant operator to upload the package containing the necessary interfaces/templates.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [TEMPLATES_OR_INTERFACES_NOT_FOUND](#)

37.10.25.6 TRANSACTION_NOT_FOUND

Explanation: The transaction does not exist or the requesting set of parties are not authorized to fetch it.

Resolution: Check the transaction id and verify that the requested transaction is visible to the requesting parties.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [TRANSACTION_NOT_FOUND](#)

37.10.26 3.3. TransactionErrorGroup

37.10.27 3.3.1. TransactionRoutingError

37.10.27.1 AUTOMATIC_TRANSFER_FOR_TRANSACTION_FAILED

Explanation: This error indicates that the automated transfer could not succeed, as the current topology does not allow the transfer to complete, mostly due to lack of confirmation permissions of the involved parties.

Resolution: Inspect the message and your topology and ensure appropriate permissions exist.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [AUTOMATIC_TRANSFER_FOR_TRANSACTION_FAILED](#)

37.10.27.2 ROUTING_INTERNAL_ERROR

Explanation: This error indicates an internal error in the Canton domain router.

Resolution: Please contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [ROUTING_INTERNAL_ERROR](#)

37.10.27.3 UNABLE_TO_GET_TOPOLOGY_SNAPSHOT

Explanation: This error indicates that topology information could not be queried.

Resolution: Check that the participant is connected to the domain.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [UNABLE_TO_GET_TOPOLOGY_SNAPSHOT](#)

37.10.28 3.3.1.1. MalformedInputErrors

37.10.28.1 DISCLOSED_CONTRACT_AUTHENTICATION_FAILED

Explanation: A provided disclosed contract could not be authenticated against the provided contract id.

Resolution: Ensure that disclosed contracts provided with command submission match the original contract creation content as sourced from the Ledger API. If the problem persists, contact the participant operator.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [DISCLOSED_CONTRACT_AUTHENTICATION_FAILED](#)

37.10.28.2 INVALID_DISCLOSED_CONTRACT

Explanation: A provided disclosed contract could not be processed.

Resolution: Ensure that disclosed contracts provided with command submission have an authenticated contract id (i.e. have been created in participant nodes running Canton protocol version 4 or higher) and match the original contract creation format and content as sourced from the Ledger API. If the problem persists, contact the participant operator.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_DISCLOSED_CONTRACT](#)

37.10.28.3 INVALID_DOMAIN_ALIAS

Explanation: The WorkflowID defined in the transaction metadata is not a valid domain alias.
Resolution: Check that the workflow ID (if specified) corresponds to a valid domain alias. A typical rejection reason is a too-long domain alias.
Category: InvalidGivenCurrentSystemStateResourceMissing
Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.
Scaladocs: [INVALID_DOMAIN_ALIAS](#)

37.10.28.4 INVALID_DOMAIN_ID

Explanation: The WorkflowID defined in the transaction metadata contains an invalid domain id.
Resolution: Check that the workflow ID (if specified) corresponds to a valid domain ID after the domain-id: marker string.
Category: InvalidGivenCurrentSystemStateResourceMissing
Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.
Scaladocs: [INVALID_DOMAIN_ID](#)

37.10.28.5 INVALID_PARTY_IDENTIFIER

Explanation: The given party identifier is not a valid Canton party identifier.
Resolution: Ensure that your commands only refer to correct and valid Canton party identifiers of parties that are properly enabled on the system
Category: InvalidIndependentOfSystemState
Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.
Scaladocs: [INVALID_PARTY_IDENTIFIER](#)

37.10.28.6 INVALID_SUBMITTER

Explanation: The party defined as a submitter can not be parsed into a valid Canton party.
Resolution: Check that you only use correctly setup party names in your application.
Category: InvalidIndependentOfSystemState
Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.
Scaladocs: [INVALID_SUBMITTER](#)

37.10.29 3.3.1.2. TopologyErrors

37.10.29.1 INFORMEES_NOT_ACTIVE

Explanation: This error indicates that the informees are known, but there is no connected domain on which all the informees are hosted.

Resolution: Ensure that there is such a domain, as Canton requires a domain where all informees are present.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INFORMEES_NOT_ACTIVE](#)

37.10.29.2 NOT_CONNECTED_TO_ALL_CONTRACT_DOMAINS

Explanation: This error indicates that the transaction is referring to contracts on domains to which this participant is currently not connected.

Resolution: Check the status of your domain connections.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [NOT_CONNECTED_TO_ALL_CONTRACT_DOMAINS](#)

37.10.29.3 NO_COMMON_DOMAIN

Explanation: This error indicates that there is no common domain to which all submitters can submit and all informees are connected.

Resolution: Check that your participant node is connected to all domains you expect and check that the parties are hosted on these domains as you expect them to be.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [NO_COMMON_DOMAIN](#)

37.10.29.4 NO_DOMAIN_FOR_SUBMISSION

Explanation: This error indicates that no valid domain was found for submission.

Resolution: Check the status of your domain connections, that packages are vetted and that you are connected to domains running recent protocol versions.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [NO_DOMAIN_FOR_SUBMISSION](#)

37.10.29.5 NO_DOMAIN_ON_WHICH_ALL_SUBMITTERS_CAN_SUBMIT

Explanation: This error indicates that a transaction has been sent where the system can not find any active + domain on which this participant can submit in the name of the given set of submitters.

Resolution: Ensure that you are connected to a domain where this participant has submission rights. Check that you are actually connected to the domains you expect to be connected and check that your participant node has the submission permission for each submitting party.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [NO_DOMAIN_ON_WHICH_ALL_SUBMITTERS_CAN_SUBMIT](#)

37.10.29.6 SUBMITTERS_NOT_ACTIVE

Explanation: This error indicates that the submitters are known, but there is no connected domain on which all the submitters are hosted.

Resolution: Ensure that there is such a domain, as Canton requires a domain where all submitters are present.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SUBMITTERS_NOT_ACTIVE](#)

37.10.29.7 SUBMITTER_ALWAYS_STAKEHOLDER

Explanation: This error indicates that the transaction requires contract transfers for which the submitter must be a stakeholder.

Resolution: Check that your participant node is connected to all domains you expect and check that the parties are hosted on these domains as you expect them to be.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SUBMITTER_ALWAYS_STAKEHOLDER](#)

37.10.29.8 UNKNOWN_CONTRACT_DOMAINS

Explanation: This error indicates that the transaction is referring to contracts whose domain is not currently known.

Resolution: Ensure all transfer operations on contracts used by the transaction have completed.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [UNKNOWN_CONTRACT_DOMAINS](#)

37.10.29.9 UNKNOWN_INFORMEES

Explanation: This error indicates that the transaction is referring to some informees that are not known on any connected domain.

Resolution: Check the list of submitted informees and check if your participant is connected to the domains you are expecting it to be.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [UNKNOWN_INFORMEES](#)

37.10.29.10 UNKNOWN_SUBMITTERS

Explanation: This error indicates that the transaction is referring to some submitters that are not known on any connected domain.

Resolution: Check the list of provided submitters and check if your participant is connected to the domains you are expecting it to be.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [UNKNOWN_SUBMITTERS](#)

37.10.30 3.3.1.3. ConfigurationErrors

37.10.30.1 INPUT_CONTRACT_HAS_UNAUTHENTICATED_ID

Explanation: An input contract uses an unauthenticated ID.

Resolution: The presence of contracts with unauthenticated IDs indicates that these contracts have likely been created using an earlier version of Canton. Unauthenticated contract IDs are deprecated as they have security implications, and are no longer allowed by default. In order to still permit the submission of transactions that use them, you must configure the participants with the *allow-for-unauthenticated-contract-ids* flag set to true. See the following point in the documentation: <https://docs.daml.com/canton/usermanual/upgrading.html#test-the-configuration-additional-change-if-you-were-running-protocol-version-3> IMPORTANT: Please note that you MUST set the flag on ALL the participants connected to the domain. Failure to do so will end up in critical failures of the participants.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INPUT_CONTRACT_HAS_UNAUTHENTICATED_ID](#)

37.10.30.2 INVALID_PRESCRIBED_DOMAIN_ID

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INVALID_PRESCRIBED_DOMAIN_ID](#)

37.10.30.3 MULTI_DOMAIN_SUPPORT_NOT_ENABLED

Explanation: This error indicates that a transaction has been submitted that requires multi-domain support. Multi-domain support is a preview feature that needs to be enabled explicitly by configuration.

Resolution: Set `canton.features.enable-preview-commands = yes`

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [MULTI_DOMAIN_SUPPORT_NOT_ENABLED](#)

37.10.30.4 SUBMISSION_DOMAIN_NOT_READY

Explanation: This error indicates that the transaction should be submitted to a domain which is not connected or not configured.

Resolution: Ensure that the domain specified in the workflowId is correctly connected.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [SUBMISSION_DOMAIN_NOT_READY](#)

37.10.31 3.3.2. SubmissionErrors

37.10.31.1 CHOSEN_MEDIATOR_IS_INACTIVE

Explanation: The mediator chosen for the transaction got deactivated before the request was sequenced.

Resolution: Resubmit.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [CHOSEN_MEDIATOR_IS_INACTIVE](#)

37.10.31.2 CONTRACT_AUTHENTICATION_FAILED

Explanation: At least one of the transaction's input contracts could not be authenticated.

Resolution: Retry the submission with correctly authenticated contracts.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [CONTRACT_AUTHENTICATION_FAILED](#)

37.10.31.3 DOMAIN_BACKPRESSURE

Explanation: This error occurs when the sequencer refuses to accept a command due to back-pressure.

Resolution: Wait a bit and retry, preferably with some backoff factor.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [DOMAIN_BACKPRESSURE](#)

37.10.31.4 DOMAIN_WITHOUT_MEDIATOR

Explanation: The participant routed the transaction to a domain without an active mediator.

Resolution: Add a mediator to the domain.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [DOMAIN_WITHOUT_MEDIATOR](#)

37.10.31.5 MALFORMED_REQUEST

Explanation: This error has not yet been properly categorised into sub-error codes.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [MALFORMED_REQUEST](#)

37.10.31.6 NOT_SEQUENCED_TIMEOUT

Explanation: This error occurs when the transaction was not sequenced within the pre-defined max-sequencing time and has therefore timed out. The max-sequencing time is derived from the transaction's ledger time via the ledger time model skews.

Resolution: Resubmit if the delay is caused by high load. If the command requires substantial processing on the participant, specify a higher minimum ledger time with the command submission so that a higher max sequencing time is derived. Alternatively, you can increase the dynamic domain parameter ledgerTimeRecordTimeTolerance.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [NOT_SEQUENCED_TIMEOUT](#)

37.10.31.7 PACKAGE_NOT_VETTED_BY_RECIPIENTS

Explanation: This error occurs if a transaction was submitted referring to a package that a receiving participant has not vetted. Any transaction view can only refer to packages that have explicitly been approved by the receiving participants.

Resolution: Ensure that the receiving participant uploads and vets the respective package.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PACKAGE_NOT_VETTED_BY_RECIPIENTS](#)

37.10.31.8 PARTICIPANT_OVERLOADED

Explanation: The participant has rejected all incoming commands during a configurable grace period.

Resolution: Configure more restrictive resource limits (enterprise only). Change applications to submit commands at a lower rate. Configure a higher value for `myParticipant.parameters.warnIfOverloadedFor`.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [PARTICIPANT_OVERLOADED](#)

37.10.31.9 SEQUENCER_REQUEST_FAILED

Explanation: This error occurs when the command cannot be sent to the domain.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [SEQUENCER_REQUEST_FAILED](#)

37.10.31.10 SUBMISSION_DURING_SHUTDOWN

Explanation: This error occurs when a command is submitted while the system is performing a shutdown.

Resolution: Assuming that the participant will restart or failover eventually, retry in a couple of seconds.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [SUBMISSION_DURING_SHUTDOWN](#)

37.10.31.11 UNKNOWN_CONTRACT_DOMAIN

Explanation: This error occurs if a transaction was submitted referring to a contract that is not known on the domain. This can occur in case of race conditions between a transaction and an archival or transfer-out.

Resolution: Check domain for submission and/or re-submit the transaction.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [UNKNOWN_CONTRACT_DOMAIN](#)

37.10.32 3.3.3. SyncServiceInjectionError

37.10.32.1 COMMAND_INJECTION_FAILURE

Explanation: This error occurs if an internal error results in an exception.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [COMMAND_INJECTION_FAILURE](#)

37.10.32.2 NODE_IS_PASSIVE_REPLICA

Explanation: This error results if a command is submitted to the passive replica.

Resolution: Send the command to the active replica.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [NODE_IS_PASSIVE_REPLICA](#)

37.10.32.3 NOT_CONNECTED_TO_ANY_DOMAIN

Explanation: This error results if a command is submitted to a participant that is not connected to any domain.

Resolution: Connect your participant to the domain where the given parties are hosted.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [NOT_CONNECTED_TO_ANY_DOMAIN](#)

37.10.33 3.3.4. LocalReject

37.10.34 3.3.4.1. MalformedRejects

37.10.34.1 LOCAL_VERDICT_BAD_ROOT_HASH_MESSAGES

Explanation: This rejection is made by a participant if a transaction does not contain valid root hash messages.

Resolution: This indicates a race condition due to a in-flight topology change, or malicious or faulty behaviour.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [LOCAL_VERDICT_BAD_ROOT_HASH_MESSAGES](#)

37.10.34.2 LOCAL_VERDICT_CREATE_EXISTING_CONTRACTS

Explanation: This error indicates that the transaction would create already existing contracts.

Resolution: This error indicates either faulty or malicious behaviour.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [LOCAL_VERDICT_CREATE_EXISTING_CONTRACTS](#)

37.10.34.3 LOCAL_VERDICT_FAILED_MODEL_CONFORMANCE_CHECK

Explanation: This rejection is made by a participant if a transaction fails a model conformance check.

Resolution: This indicates either malicious or faulty behaviour.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [LOCAL_VERDICT_FAILED_MODEL_CONFORMANCE_CHECK](#)

37.10.34.4 LOCAL_VERDICT_MALFORMED_PAYLOAD

Explanation: This rejection is made by a participant if a view of the transaction is malformed.

Resolution: This indicates either malicious or faulty behaviour.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [LOCAL_VERDICT_MALFORMED_PAYLOAD](#)

37.10.34.5 LOCAL_VERDICT_MALFORMED_REQUEST

Explanation: This rejection is made by a participant if a request is malformed.

Resolution: Please contact support.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [LOCAL_VERDICT_MALFORMED_REQUEST](#)

37.10.35 3.3.4.2. ConsistencyRejections

37.10.35.1 LOCAL_VERDICT_DUPLICATE_KEY

Explanation: If the participant provides unique contract key support, this error will indicate that a transaction would create a unique key which already exists.

Resolution: It depends on your use case and application whether and when retrying makes sense or not.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [LOCAL_VERDICT_DUPLICATE_KEY](#)

37.10.35.2 LOCAL_VERDICT_INACTIVE_CONTRACTS

Explanation: The transaction is referring to contracts that have either been previously archived, transferred to another domain, or do not exist.

Resolution: Inspect your contract state and try a different transaction.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [LOCAL_VERDICT_INACTIVE_CONTRACTS](#)

37.10.35.3 LOCAL_VERDICT_INCONSISTENT_KEY

Explanation: If the participant provides unique contract key support, this error will indicate that a transaction expected a key to be unallocated, but a contract for the key already exists.

Resolution: It depends on your use case and application whether and when retrying makes sense or not.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [LOCAL_VERDICT_INCONSISTENT_KEY](#)

37.10.35.4 LOCAL_VERDICT_LOCKED_CONTRACTS

Explanation: The transaction is referring to locked contracts which are in the process of being created, transferred, or archived by another transaction. If the other transaction fails, this transaction could be successfully retried.

Resolution: Retry the transaction

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [LOCAL_VERDICT_LOCKED_CONTRACTS](#)

37.10.35.5 LOCAL_VERDICT_LOCKED_KEYS

Explanation: The transaction is referring to locked keys which are in the process of being modified by another transaction.

Resolution: Retry the transaction

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [LOCAL_VERDICT_LOCKED_KEYS](#)

37.10.36 3.3.4.3. TimeRejects

37.10.36.1 LOCAL_VERDICT_LEDGER_TIME_OUT_OF_BOUND

Explanation: This error is thrown if the ledger time and the record time differ more than permitted. This can happen in an overloaded system due to high latencies or for transactions with long interpretation times.

Resolution: For long-running transactions, specify a ledger time with the command submission or adjust the dynamic domain parameter ledgerTimeRecordTimeTolerance (and possibly the participant and mediator reaction timeout). For short-running transactions, simply retry.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [LOCAL_VERDICT_LEDGER_TIME_OUT_OF_BOUND](#)

37.10.36.2 LOCAL_VERDICT_SUBMISSION_TIME_OUT_OF_BOUND

Explanation: This error is thrown if the submission time and the record time differ more than permitted. This can happen in an overloaded system due to high latencies or for transactions with long interpretation times.

Resolution: For long-running transactions, adjust the ledger time bounds used with the command submission. For short-running transactions, simply retry.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [LOCAL_VERDICT_SUBMISSION_TIME_OUT_OF_BOUND](#)

37.10.36.3 LOCAL_VERDICT_TIMEOUT

Explanation: This rejection is sent if the participant locally determined a timeout.

Resolution: In the first instance, resubmit your transaction. If the rejection still appears spuriously, consider increasing the *participantResponseTimeout* or *mediatorReactionTimeout* values in the *DynamicDomainParameters*. If the rejection appears unrelated to timeout settings, validate that the sequencer and mediator function correctly.

Category: *ContentionOnSharedResources*

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with gRPC-status ABORTED including a detailed error message.

Scaladocs: [LOCAL_VERDICT_TIMEOUT](#)

37.10.37 3.3.4.4. TransferInRejects

37.10.37.1 TRANSFER_IN_ALREADY_COMPLETED

Explanation: This rejection is emitted by a participant if a transfer-in has already been completed.

Category: *InvalidGivenCurrentSystemStateResourceExists*

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with gRPC-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [TRANSFER_IN_ALREADY_COMPLETED](#)

37.10.37.2 TRANSFER_IN_CONTRACT_ALREADY_ACTIVE

Explanation: This rejection is emitted by a participant if a transfer-in has already been made by another entity.

Category: *InvalidGivenCurrentSystemStateResourceExists*

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with gRPC-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [TRANSFER_IN_CONTRACT_ALREADY_ACTIVE](#)

37.10.37.3 TRANSFER_IN_CONTRACT_ALREADY_ARCHIVED

Explanation: This rejection is emitted by a participant if a transfer would be invoked on an already archived contract.

Category: *InvalidGivenCurrentSystemStateResourceMissing*

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with gRPC-status NOT_FOUND including a detailed error message.

Scaladocs: [TRANSFER_IN_CONTRACT_ALREADY_ARCHIVED](#)

37.10.37.4 TRANSFER_IN_CONTRACT_IS_LOCKED

Explanation: This rejection is emitted by a participant if a transfer-in is referring to an already locked contract.

Category: `ContentionOnSharedResources`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status` `ABORTED` including a detailed error message.

Scaladocs: [TRANSFER_IN_CONTRACT_IS_LOCKED](#)

37.10.38 3.3.4.5. TransferOutRejects

37.10.38.1 TRANSFER_OUT_ACTIVENESS_CHECK_FAILED

Explanation: Activeness check failed for transfer out submission. This rejection occurs if the contract to be transferred has already been transferred or is currently locked (due to a competing transaction) on domain.

Resolution: Depending on your use-case and your expectation, retry the transaction.

Category: `InvalidGivenCurrentSystemStateResourceMissing`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status` `NOT_FOUND` including a detailed error message.

Scaladocs: [TRANSFER_OUT_ACTIVENESS_CHECK_FAILED](#)

37.10.39 3.3.5. CommandDeduplicationError

37.10.39.1 MALFORMED_DEDUPLICATION_OFFSET

Explanation: The specified deduplication offset is syntactically malformed.

Resolution: Use a deduplication offset that was produced by this participant node.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status` `INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [MALFORMED_DEDUPLICATION_OFFSET](#)

37.10.40 3.4. SyncServiceError

37.10.40.1 PARTY_ALLOCATION_WITHOUT_CONNECTED_DOMAIN

Explanation: The participant is not connected to a domain and can therefore not allocate a party because the party notification is configured as `party-notification.type = via-domain`.

Resolution: Connect the participant to a domain first or change the participant's party notification config to `eager`.

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status` `FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [PARTY_ALLOCATION_WITHOUT_CONNECTED_DOMAIN](#)

37.10.40.2 SYNC_SERVICE_ALARM

Explanation: The participant has detected that another node is behaving maliciously.

Resolution: Contact support.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [SYNC_SERVICE_ALARM](#)

37.10.40.3 SYNC_SERVICE_ALREADY_ADDED

Explanation: This error results on an attempt to register a new domain under an alias already in use.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [SYNC_SERVICE_ALREADY_ADDED](#)

37.10.40.4 SYNC_SERVICE_DOMAIN_BECAME_PASSIVE

Explanation: This error is logged when a sync domain is disconnected because the participant became passive.

Resolution: Fail over to the active participant replica.

Category: TransientServerFailure

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [SYNC_SERVICE_DOMAIN_BECAME_PASSIVE](#)

37.10.40.5 SYNC_SERVICE_DOMAIN_DISABLED_US

Explanation: This error is logged when the synchronization service shuts down because the remote domain has disabled this participant.

Resolution: Contact the domain operator and inquire why you have been booted out.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SYNC_SERVICE_DOMAIN_DISABLED_US](#)

37.10.40.6 SYNC_SERVICE_DOMAIN_DISCONNECTED

Explanation: This error is logged when a sync domain is unexpectedly disconnected from the Canton sync service (after having previously been connected)

Resolution: Please contact support and provide the failure reason.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [SYNC_SERVICE_DOMAIN_DISCONNECTED](#)

37.10.40.7 SYNC_SERVICE_DOMAIN_MUST_BE_OFFLINE

Explanation: This error is emitted when an operation is attempted such as repair that requires the domain connection to be disconnected and clean.

Resolution: Disconnect the domain before attempting the command.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SYNC_SERVICE_DOMAIN_MUST_BE_OFFLINE](#)

37.10.40.8 SYNC_SERVICE_DOMAIN_MUST_NOT_HAVE_IN_FLIGHT_TRANSACTIONS

Explanation: This error is emitted when a domain migration is attempted while transactions are still in-flight on the source domain.

Resolution: Ensure the source domain has no in-flight transactions by reconnecting participants to the source domain, halting activity on the participants and waiting for in-flight transactions to complete or time out. Afterwards invoke *migrate_domain* again. As a last resort, you may force the domain migration ignoring in-flight transactions using the *force* flag on the command. Be advised, forcing a migration may lead to a ledger fork.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SYNC_SERVICE_DOMAIN_MUST_NOT_HAVE_IN_FLIGHT_TRANSACTIONS](#)

37.10.40.9 SYNC_SERVICE_DOMAIN_STATUS_MUST_BE_INACTIVE

Explanation: This error is logged when a sync domain is not inactive.

Resolution: If you attempt to purge a domain that has not been deactivated, this error will be emitted. Please ensure that the specified domain has a status of *Inactive* before attempting to purge it.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SYNC_SERVICE_DOMAIN_STATUS_MUST_BE_INACTIVE](#)

37.10.40.10 SYNC_SERVICE_DOMAIN_STATUS_NOT_ACTIVE

Explanation: This error is logged when a sync domain has a non-active status.

Resolution: If you attempt to connect to a domain that has either been migrated off or has a pending migration, this error will be emitted. Please complete the migration before attempting to connect to it.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SYNC_SERVICE_DOMAIN_STATUS_NOT_ACTIVE](#)

37.10.40.11 SYNC_SERVICE_INTERNAL_ERROR

Explanation: This error indicates an internal issue.

Resolution: Please contact support and provide the failure reason.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [SYNC_SERVICE_INTERNAL_ERROR](#)

37.10.40.12 SYNC_SERVICE_UNKNOWN_DOMAIN

Explanation: This error results if a domain connectivity command is referring to a domain alias that has not been registered.

Resolution: Please confirm the domain alias is correct, or configure the domain before (re)connecting.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [SYNC_SERVICE_UNKNOWN_DOMAIN](#)

37.10.41 3.4.1. SyncDomainMigrationError

37.10.41.1 BROKEN_DOMAIN_MIGRATION

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [BROKEN_DOMAIN_MIGRATION](#)

37.10.41.2 INVALID_DOMAIN_MIGRATION_REQUEST

Explanation: This error results when invalid arguments are passed to the migration command.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INVALID_DOMAIN_MIGRATION_REQUEST](#)

37.10.42 3.4.2. DomainRegistryError

37.10.42.1 DOMAIN_REGISTRY_INTERNAL_ERROR

Explanation: This error indicates that there has been an internal error noticed by Canton.

Resolution: Contact support and provide the failure reason.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [DOMAIN_REGISTRY_INTERNAL_ERROR](#)

37.10.42.2 TOPOLOGY_CONVERSION_ERROR

Explanation: This error indicates that there was an error converting topology transactions during connecting to a domain.

Resolution: Contact the operator of the topology management for this node.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [TOPOLOGY_CONVERSION_ERROR](#)

37.10.43 3.4.2.1. ConfigurationErrors

37.10.43.1 CANNOT_ISSUE_DOMAIN_TRUST_CERTIFICATE

Explanation: This error indicates that the participant can not issue a domain trust certificate. Such a certificate is necessary to become active on a domain. Therefore, it must be present in the authorized store of the participant topology manager.

Resolution: Manually upload a valid domain trust certificate for the given domain or upload the necessary certificates such that participant can issue such certificates automatically.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [CANNOT_ISSUE_DOMAIN_TRUST_CERTIFICATE](#)

37.10.43.2 DOMAIN_PARAMETERS_CHANGED

Explanation: Error indicating that the domain parameters have been changed, while this isn't supported yet.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DOMAIN_PARAMETERS_CHANGED](#)

37.10.43.3 INCOMPATIBLE_UNIQUE_CONTRACT_KEYS_MODE

Explanation: This error indicates that the domain this participant is trying to connect to is a domain where unique contract keys are supported, while this participant is already connected to other domains. Multiple domains and unique contract keys are mutually exclusive features.

Resolution: Use isolated participants for domains that require unique keys.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INCOMPATIBLE_UNIQUE_CONTRACT_KEYS_MODE](#)

37.10.43.4 INVALID_DOMAIN_CONNECTION

Explanation: This error indicates there is a validation error with the configured connections for the domain

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [INVALID_DOMAIN_CONNECTION](#)

37.10.43.5 MISCONFIGURED_STATIC_DOMAIN_PARAMETERS

Explanation: This error indicates that the participant is configured to connect to multiple domain sequencers but their static domain parameters are different from other sequencers.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [MISCONFIGURED_STATIC_DOMAIN_PARAMETERS](#)

37.10.43.6 SEQUENCERS_FROM_DIFFERENT_DOMAINS_ARE_CONFIGURED

Explanation: This error indicates that the participant is configured to connect to multiple domain sequencers from different domains.

Resolution: Carefully verify the connection settings.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCERS_FROM_DIFFERENT_DOMAINS_ARE_CONFIGURED](#)

37.10.44 3.4.2.2. HandshakeErrors

37.10.44.1 DOMAIN_ALIAS_DUPLICATION

Explanation: This error indicates that the domain alias was previously used to connect to a domain with a different domain id. This is a known situation when an existing participant is trying to connect to a freshly re-initialised domain.

Resolution: Carefully verify the connection settings.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DOMAIN_ALIAS_DUPLICATION](#)

37.10.44.2 DOMAIN_CRYPTO_HANDSHAKE_FAILED

Explanation: This error indicates that the domain is using crypto settings which are either not supported or not enabled on this participant.

Resolution: Consult the error message and adjust the supported crypto schemes of this participant.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DOMAIN_CRYPTO_HANDSHAKE_FAILED](#)

37.10.44.3 DOMAIN_HANDSHAKE_FAILED

Explanation: This error indicates that the participant to domain handshake has failed.

Resolution: Inspect the provided reason for more details and contact support.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DOMAIN_HANDSHAKE_FAILED](#)

37.10.44.4 DOMAIN_ID_MISMATCH

Explanation: This error indicates that the domain-id does not match the one that the participant expects. If this error happens on a first connect, then the domain id defined in the domain connection settings does not match the remote domain. If this happens on a reconnect, then the remote domain has been reset for some reason.

Resolution: Carefully verify the connection settings.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DOMAIN_ID_MISMATCH](#)

37.10.44.5 SERVICE_AGREEMENT_ACCEPTANCE_FAILED

Explanation: This error indicates that the domain requires the participant to accept a service agreement before connecting to it.

Resolution: Use the commands `$participant.domains.get_agreement` and `$participant.domains.accept_agreement` to accept the agreement.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SERVICE_AGREEMENT_ACCEPTANCE_FAILED](#)

37.10.45 3.4.2.3. ConnectionErrors

37.10.45.1 DOMAIN_IS_NOT_AVAILABLE

Explanation: This error results if the GRPC connection to the domain service fails with GRPC status UNAVAILABLE.

Resolution: Check your connection settings and ensure that the domain can really be reached.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [DOMAIN_IS_NOT_AVAILABLE](#)

37.10.45.2 FAILED_TO_CONNECT_TO_SEQUENCER

Explanation: This error indicates that the participant failed to connect to the sequencer.

Resolution: Inspect the provided reason.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [FAILED_TO_CONNECT_TO_SEQUENCER](#)

37.10.45.3 FAILED_TO_CONNECT_TO_SEQUENCERS

Explanation: This error indicates that the participant failed to connect to the sequencers.

Resolution: Inspect the provided reason.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [FAILED_TO_CONNECT_TO_SEQUENCERS](#)

37.10.45.4 GRPC_CONNECTION_FAILURE

Explanation: This error indicates that the participant failed to connect due to a general GRPC error.

Resolution: Inspect the provided reason and contact support.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [GRPC_CONNECTION_FAILURE](#)

37.10.45.5 PARTICIPANT_IS_NOT_ACTIVE

Explanation: This error indicates that the connecting participant has either not yet been activated by the domain operator. If the participant was previously successfully connected to the domain, then this error indicates that the domain operator has deactivated the participant.

Resolution: Contact the domain operator and inquire the permissions your participant node has on the given domain.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PARTICIPANT_IS_NOT_ACTIVE](#)

37.10.46 3.5. AdminWorkflowServices

37.10.46.1 CAN_NOT_AUTOMATICALLY_VET_ADMIN_WORKFLOW_PACKAGE

Explanation: This error indicates that the admin workflow package could not be vetted. The admin workflows is a set of packages that are pre-installed and can be used for administrative processes. The error can happen if the participant is initialised manually but is missing the appropriate signing keys or certificates in order to issue new topology transactions within the participants namespace. The admin workflows can not be used until the participant has vetted the package.

Resolution: This error can be fixed by ensuring that an appropriate vetting transaction is issued in the name of this participant and imported into this participant node. If the corresponding certificates have been added after the participant startup, then this error can be fixed by either restarting the participant node, issuing the vetting transaction manually or re-uploading the Dar (leaving the vetAllPackages argument as true)

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [CAN_NOT_AUTOMATICALLY_VET_ADMIN_WORKFLOW_PACKAGE](#)

37.10.47 3.6. RepairServiceError

37.10.47.1 CONTRACT_PURGE_ERROR

Explanation: A contract cannot be purged due to an error.

Resolution: Retry after operator intervention.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [CONTRACT_PURGE_ERROR](#)

37.10.47.2 CONTRACT_SERIALIZATION_ERROR

Explanation: A contract cannot be serialized due to an error.

Resolution: Retry after operator intervention.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [CONTRACT_SERIALIZATION_ERROR](#)

37.10.47.3 IMPORT_ACS_ERROR

Explanation: Import Acs has failed.

Resolution: Retry after operator intervention.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [IMPORT_ACS_ERROR](#)

37.10.47.4 INCONSISTENT_ACS_SNAPSHOT

Explanation: The ACS snapshot cannot be returned because it contains inconsistencies. This is likely due to the request happening concurrently with pruning.

Resolution: Retry the operation

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [INCONSISTENT_ACS_SNAPSHOT](#)

37.10.47.5 INVALID_ACS_SNAPSHOT_TIMESTAMP

Explanation: The participant does not support serving an ACS snapshot at the requested timestamp, likely because some concurrent processing has not yet finished.

Resolution: Make sure that the specified timestamp has been obtained from the participant in some way. If so, retry after a bit (possibly repeatedly).

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [INVALID_ACS_SNAPSHOT_TIMESTAMP](#)

37.10.47.6 INVALID_ARGUMENT_REPAIR

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_ARGUMENT_REPAIR](#)

37.10.47.7 UNAVAILABLE_ACS_SNAPSHOT

Explanation: The participant does not support serving an ACS snapshot at the requested timestamp because its database has already been pruned, e.g., by the continuous background pruning process.

Resolution: The snapshot at the requested timestamp is no longer available. Pick a more recent timestamp if possible.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [UNAVAILABLE_ACS_SNAPSHOT](#)

37.10.47.8 UNSUPPORTED_PROTOCOL_VERSION_PARTICIPANT

Explanation: The participant does not support the requested protocol version.

Resolution: Specify a protocol version that the participant supports or upgrade the participant to a release that supports the requested protocol version.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [UNSUPPORTED_PROTOCOL_VERSION_PARTICIPANT](#)

37.10.48 3.7. CantonPackageServiceError

37.10.48.1 DAR_NOT_FOUND

Explanation: The hash specified in the request does not match a DAR stored on the participant.

Resolution: Check the provided hash and re-try the operation.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [DAR_NOT_FOUND](#)

37.10.48.2 PACKAGE_MISSING_DEPENDENCIES

Explanation: An operation could not be executed due to a missing package dependency.

Resolution: Fix the broken dependency state by re-uploading the missing package and retry the operation.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [PACKAGE_MISSING_DEPENDENCIES](#)

37.10.48.3 PACKAGE_OR_DAR_REMOVAL_ERROR

Explanation: Errors raised by the Package Service on package removal.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PACKAGE_OR_DAR_REMOVAL_ERROR](#)

37.10.49 3.8. LedgerApiErrors

37.10.49.1 HEAP_MEMORY_OVER_LIMIT

Explanation: This error happens when the JVM heap memory pool exceeds a pre-configured limit.

Resolution: The following actions can be taken: 1. Review the historical use of heap space by inspecting the metric given in the message. 2. Review the current heap space limits configured in the rate limiting configuration. 3. Try to space out requests that are likely to require a large amount of memory to process.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [HEAP_MEMORY_OVER_LIMIT](#)

37.10.49.2 LEDGER_API_INTERNAL_ERROR

Explanation: This error occurs if there was an unexpected error in the Ledger API.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [LEDGER_API_INTERNAL_ERROR](#)

37.10.49.3 MAXIMUM_NUMBER_OF_STREAMS

Explanation: This error happens when the number of concurrent gRPC streaming requests exceeds the configured limit.

Resolution: The following actions can be taken: 1. Review the historical need for concurrent streaming by inspecting the metric given in the message. 2. Review the maximum streams limit configured in the rate limiting configuration. 3. Try to space out streaming requests such that they do not need to run in parallel with each other.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [MAXIMUM_NUMBER_OF_STREAMS](#)

37.10.49.4 PARTICIPANT_BACKPRESSURE

Explanation: This error occurs when a participant rejects a command due to excessive load. Load can be caused by the following factors: 1. when commands are submitted to the participant through its Ledger API, 2. when the participant receives requests from other participants through a connected domain.

Resolution: Wait a bit and retry, preferably with some backoff factor. If possible, ask other participants to send fewer requests; the domain operator can enforce this by imposing a rate limit.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [PARTICIPANT_BACKPRESSURE](#)

37.10.49.5 THREADPOOL_OVERLOADED

Explanation: This happens when the rate of submitted gRPC requests requires more CPU or database power than is available.

Resolution: The following actions can be taken: Here the 'queue size' for the threadpool is considered as reported by the executor itself. 1. Review the historical 'queue size' growth by inspecting the metric given in the message. 2. Review the maximum 'queue size' limits configured in the rate limiting configuration. 3. Try to space out requests that are likely to require a lot of CPU or database power.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [THREADPOOL_OVERLOADED](#)

37.10.50 3.9. IndexErrors

37.10.51 3.9.1. DatabaseErrors

37.10.51.1 INDEX_DB_INVALID_RESULT_SET

Explanation: This error occurs if the result set returned by a query against the Index database is invalid.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INDEX_DB_INVALID_RESULT_SET](#)

37.10.51.2 INDEX_DB_SQL_NON_TRANSIENT_ERROR

Explanation: This error occurs if a non-transient error arises when executing a query against the index database.

Resolution: Contact the participant operator.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INDEX_DB_SQL_NON_TRANSIENT_ERROR](#)

37.10.51.3 INDEX_DB_SQL_TRANSIENT_ERROR

Explanation: This error occurs if a transient error arises when executing a query against the index database.

Resolution: Re-submit the request.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [INDEX_DB_SQL_TRANSIENT_ERROR](#)

37.10.52 3.10. PruningServiceError

37.10.52.1 INTERNAL_PRUNING_ERROR

Explanation: Pruning has failed because of an internal server error.

Resolution: Identify the error in the server log.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [INTERNAL_PRUNING_ERROR](#)

37.10.52.2 NON_CANTON_OFFSET

Explanation: The supplied offset has an unexpected lengths.

Resolution: Ensure the offset has originated from this participant and is 9 bytes in length.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [NON_CANTON_OFFSET](#)

37.10.52.3 NO_INTERNAL_PARTICIPANT_DATA_BEFORE

Explanation: The participant does not hold internal ledger state up to and including the specified time and offset.

Resolution: The participant holds no internal ledger data before or at the time and offset specified as parameters to *find_safe_offset*. Typically this means that the participant has already pruned all internal data up to the specified time and offset. Accordingly this error indicates that no safe offset to prune could be located prior.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [NO_INTERNAL_PARTICIPANT_DATA_BEFORE](#)

37.10.52.4 PRUNING_NOT_SUPPORTED_IN_COMMUNITY_EDITION

Explanation: Pruning is not supported in the Community Edition.

Resolution: Upgrade to the Enterprise Edition.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [PRUNING_NOT_SUPPORTED_IN_COMMUNITY_EDITION](#)

37.10.52.5 SHUTDOWN_INTERRUPTED_PRUNING

Explanation: Pruning has been aborted because the participant is shutting down.

Resolution: After the participant is restarted, the participant ensures that it is in a consistent state. Therefore no intervention is necessary. After the restart, pruning can be invoked again as usual to prune the participant up to the desired offset.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [SHUTDOWN_INTERRUPTED_PRUNING](#)

37.10.52.6 UNSAFE_TO_PRUNE

Explanation: Pruning is not possible at the specified offset at the current time.

Resolution: Specify a lower offset or retry pruning after a while. Generally, you can only prune older events. In particular, the events must be older than the sum of mediator reaction timeout and participant timeout for every domain. And, you can only prune events that are older than the deduplication time configured for this participant. Therefore, if you observe this error, you either just prune older events or you adjust the settings for this participant. The error details field *safe_offset* contains the highest offset that can currently be pruned, if any.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [UNSAFE_TO_PRUNE](#)

37.10.53 3.11. ParticipantReplicationServiceError

37.10.53.1 PARTICIPANT_REPLICATION_INTERNAL_ERROR

Explanation: Internal error emitted upon internal participant replication errors

Resolution: Contact support

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [PARTICIPANT_REPLICATION_INTERNAL_ERROR](#)

37.10.53.2 PARTICIPANT_REPLICATION_NOT_SUPPORTED_BY_STORAGE

Explanation: Error emitted if the supplied storage configuration does not support replication.

Resolution: Use a participant storage backend supporting replication.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PARTICIPANT_REPLICATION_NOT_SUPPORTED_BY_STORAGE](#)

37.10.54 3.12. CommonErrors

37.10.54.1 REQUEST_DEADLINE_EXCEEDED

Explanation: The request has not been submitted for processing as its predefined deadline has expired.

Resolution: Retry the request with a greater deadline.

Category: DeadlineExceededRequestStateUnknown

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status DEADLINE_EXCEEDED including a detailed error message.

Scaladocs: [REQUEST_DEADLINE_EXCEEDED](#)

37.10.54.2 REQUEST_TIME_OUT

Explanation: This rejection is given when a request processing status is not known and a time-out is reached.

Resolution: Retry for transient problems. If non-transient contact the operator as the time-out limit might be too short.

Category: DeadlineExceededRequestStateUnknown

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status DEADLINE_EXCEEDED including a detailed error message.

Scaladocs: [REQUEST_TIME_OUT](#)

37.10.54.3 SERVER_IS_SHUTTING_DOWN

Explanation: This rejection is given when the participant node is shutting down.

Resolution: Retry the request against an active and available node or contact the participant operator if the error is unexpected.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [SERVER_IS_SHUTTING_DOWN](#)

37.10.54.4 SERVICE_INTERNAL_ERROR

Explanation: This error occurs if one of the services encountered an unexpected exception.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [SERVICE_INTERNAL_ERROR](#)

37.10.54.5 SERVICE_NOT_RUNNING

Explanation: This rejection is given when the requested service is not running. It has not started or has already been shut down.

Resolution: Retry re-submitting the request. If the error persists, contact the participant operator.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [SERVICE_NOT_RUNNING](#)

37.10.54.6 UNSUPPORTED_OPERATION

Explanation: This error category is used to signal that an unimplemented code-path has been triggered by a client or participant operator request.

Resolution: This error is caused by a participant node misconfiguration or by an implementation bug. Resolution requires participant operator intervention.

Category: InternalUnsupportedOperation

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status UNIMPLEMENTED without any details for security reasons.

Scaladocs: [UNSUPPORTED_OPERATION](#)

37.10.55 4. EthereumErrors

37.10.56 4.1. ConfigurationErrors

37.10.56.1 AHEAD_OF_HEAD

Explanation: This warning is logged on startup if the sequencer is configured to only start reading from a block that wasn't mined yet by the blockchain (e.g. sequencer is supposed to start reading from block 500, but the latest block is only 100). This is likely due to a misconfiguration.

Resolution: This issue frequently occurs when the blockchain is reset but the sequencer database configuration is not updated or the sequencer database (which persists the last block that was read by the sequencer) is not reset. Validate these settings and ensure that the sequencer is still reading from the same blockchain.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [AHEAD_OF_HEAD](#)

37.10.56.2 ATTEMPT_TO_CHANGE_IMMUTABLE_VALUE

Explanation: The sequencer smart contract has detected that a value that is immutable after being set for the first time (either the signing tolerance or the topology manager ID) was attempted to be changed. Most frequently this error occurs during testing when a Canton Ethereum sequencer process without persistence is restarted while pointing to the same smart sequencer contract. An Ethereum sequencer attempts to set the topology manager ID during initialization, however, without persistence the topology manager ID is randomly regenerated on the restart which leads to the sequencer attempting to change the topology manager ID in the sequencer smart contract.

Resolution: Deploy a new instance of the sequencer contract and configure the Ethereum sequencer to use that instance. If the errors occur because an Ethereum sequencer process is restarted without persistence, deploy a fresh instance of the sequencer contract and configure persistence for restarts.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [ATTEMPT_TO_CHANGE_IMMUTABLE_VALUE](#)

37.10.56.3 BESU_VERSION_MISMATCH

Explanation: This error is logged when the sequencer detects that the version of the Besu client it connects to is not what is expected / supported.

Resolution: Either deploy the documented required version or set `canton.parameters.non-standard-config = true`.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [BESU_VERSION_MISMATCH](#)

37.10.56.4 ETHEREUM_CANT_QUERY_VERSION

Explanation: As one of the first steps when initializing a Besu sequencer, Canton attempts to query the version (attribute) of the Sequencer.sol contract.

Resolution: Usually, the root cause of this is a deployment or configuration problem. Ensure that a Sequencer.sol contract is deployed on the configured address on the latest block when attempting to initialize the Canton Besu sequencer node. If this error persists, a malicious user may be attempting to interfere with the Ethereum network.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [ETHEREUM_CANT_QUERY_VERSION](#)

37.10.56.5 MANY_BLOCKS_BEHIND_HEAD

Explanation: This error is logged when the sequencer is currently processing blocks that are very far behind the head of the blockchain of the connected Ethereum network. The Ethereum sequencer won't observe new transactions in the blockchain until it has caught up to the head. This may take a long time depending on the blockchain length and number of Canton transaction in the blocks. Empirically, we have observed that the Canton sequencer processes roughly 500 empty blocks/second. This may vary strongly for non-empty blocks. The sequencer logs once it has caught up to within *blocksBehindBlockchainHead* blocks behind the blockchain head.

Resolution: Wait until the sequencer has caught up to the head of the blockchain. Alternatively, consider changing the configuration of *block-to-read-from* of the Ethereum sequencer when initializing it against an Ethereum network that already mined a lot of blocks.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [MANY_BLOCKS_BEHIND_HEAD](#)

37.10.56.6 NOT_FREE_GAS_NETWORK

Explanation: This error is logged when during setup the sequencer detects that it isn't connected to a free-gas network. This usually leads to transactions silently being dropped by Ethereum nodes. You should only use a non-free-gas network, if you have configured an Ethereum wallet for the sequencer to use and have given it gas.

Resolution: Change the configuration of the Ethereum network to a free-gas network.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [NOT_FREE_GAS_NETWORK](#)

37.10.56.7 WRONG_EVM_BYTECODE

Explanation: Canton validates on startup that the configured address on the blockchain contains the EVM bytecode of the sequencer smart contract in the latest block. This error indicates that no bytecode or the wrong bytecode was found. This is a serious error and means that the sequencer can't sequence events.

Resolution: This frequently error occurs when updating the Canton system without updating the sequencer contract deployed on the blockchain. Validate that the sequencer contract corresponding to the current Canton release is deployed in the latest blockchain blocks on the configured address. Another common reason for this error is that the wrong contract address was configured.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [WRONG_EVM_BYTECODE](#)

37.10.57 4.2. TransactionErrors

37.10.57.1 ETHEREUM_TRANSACTION_INVALID

Explanation: This error happens when the Sequencer Ethereum application reads a transaction from the blockchain which is malformed (e.g. invalid member, arguments aren't parseable or too large). This could happen if a malicious or faulty Ethereum Sequencer node is placing faulty data on the blockchain.

Resolution: Generally, Canton should recover automatically from this error. The faulty transactions are simply skipped by all non-malicious/non-faulty sequencers in a deterministic way, so the integrity of the event stream across sequencer nodes should be maintained. If you continue to see this error, investigate whether some of the sequencer nodes in the network are misbehaving.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [ETHEREUM_TRANSACTION_INVALID](#)

37.10.57.2 ETHEREUM_TRANSACTION_RECEIPT_FETCHING_FAILED

Explanation: This error occurs when the Ethereum sequencer attempts to fetch the transaction receipt for a previously submitted transaction but receives an exception. Usually, this is caused by network errors, the Ethereum client node being overloaded or the Ethereum sequencer reaching its *transactionReceiptPollingAttempts* for a given transaction. The fetching of transaction receipts of submitted transactions is separate from the Ethereum sequencer's read-stream used to ingest new transactions. Thus, in this sense, this error is purely informative and can be caused by transient issues (such as a transient network outage). Note, that the Canton nonce manager refreshes his cache whenever this error occurs which may unblock stuck transactions with a too-high nonce.

Resolution: Usually, this error should resolve by itself. If you frequently see this error, ensure that the Ethereum account of the Ethereum sequencer is used by no one else and that the Ethereum client doesn't drop submitted transactions through being overloaded or reaching a full txpool. If this errors keeps occurring, please contact support.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [ETHEREUM_TRANSACTION_RECEIPT_FETCHING_FAILED](#)

37.10.57.3 ETHEREUM_TRANSACTION_SUBMISSION_FAILED

Explanation: This error is logged when the Sequencer Ethereum application receives an error when attempting to submit a transaction to the transaction pool of the Ethereum client. Common causes for this are network errors, or when the Ethereum account of the Sequencer Ethereum application is used by another application. Less commonly, this error might also indirectly be caused if the transaction pool of the Ethereum client is full or flushed.

Resolution: Generally, Canton should recover automatically from this error. If you continue to see this error, investigate possible root causes such as poor network connections, if the Ethereum wallet of the Ethereum Sequencer application is being reused by another application, and the health of the Ethereum client.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [ETHEREUM_TRANSACTION_SUBMISSION_FAILED](#)

37.10.58 5. TopologyManagementErrorGroup

37.10.59 5.1. TopologyManagerError

37.10.59.1 DUPLICATE_TOPOLOGY_TRANSACTION

Explanation: This error indicates that a transaction has already been added previously.

Resolution: Nothing to do as the transaction is already registered. Note however that a revocation is + final. If you want to re-enable a statement, you need to re-issue an new transaction.

Category: InvalidGivenCurrentSystemStateResourceExists

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ALREADY_EXISTS including a detailed error message.

Scaladocs: [DUPLICATE_TOPOLOGY_TRANSACTION](#)

37.10.59.2 ILLEGAL_REMOVAL_OF_DOMAIN_TRUST_CERTIFICATE

Explanation: This error indicates that a participant is trying to rescind their domain trust certificate while still being hosting parties.

Resolution: The participant should work with the owners of the parties mentioned in the `parties` field in the error details metadata to get itself removed from the list of hosting participants of those parties.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [ILLEGAL_REMOVAL_OF_DOMAIN_TRUST_CERTIFICATE](#)

37.10.59.3 INCREASE_OF_LEDGER_TIME_RECORD_TIME_TOLERANCE

Explanation: This error indicates that it has been attempted to increase the `ledgerTimeRecordTimeTolerance` domain parameter in an insecure manner. Increasing this parameter may disable security checks and can therefore be a security risk.

Resolution: Make sure that the new value of `ledgerTimeRecordTimeTolerance` is at most half of the `mediatorDeduplicationTimeout` domain parameter. Use `myDomain.service.set_ledger_time_record_time_tolerance` for securely increasing `ledgerTimeRecordTimeTolerance`. Alternatively, add the `force = true` flag to your command, if security is not a concern for you. The security checks will be effective again after twice the new value of `ledgerTimeRecordTimeTolerance`. Using `force = true` is safe upon domain bootstrapping.

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [INCREASE_OF_LEDGER_TIME_RECORD_TIME_TOLERANCE](#)

37.10.59.4 INSUFFICIENT_KEYS

Explanation: This error indicates that members referenced in a topology transaction have not declared at least one signing key or at least 1 encryption key or both.

Resolution: Ensure that all members referenced in the topology transaction have declared at least one signing key and at least one encryption key, then resubmit the failed transaction. The metadata details of this error contain the members with the missing keys in the field `members`.

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [INSUFFICIENT_KEYS](#)

37.10.59.5 INVALID_DOMAIN

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [INVALID_DOMAIN](#)

37.10.59.6 INVALID_THRESHOLD

Explanation: This error indicates that a threshold in the submitted transaction was higher than the number of members that would have to satisfy that threshold.

Resolution: Submit the topology transaction with a lower threshold. The metadata details of this error contain the expected maximum in the field `expectedMaximum`.

Category: `InvalidIndependentOfSystemState`

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status INVALID_ARGUMENT` including a detailed error message.

Scaladocs: [INVALID_THRESHOLD](#)

37.10.59.7 INVALID_TOPOLOGY_TX_SIGNATURE_ERROR

Explanation: This error indicates that the uploaded signed transaction contained an invalid signature.

Resolution: Ensure that the transaction is valid and uses a crypto version understood by this participant.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_TOPOLOGY_TX_SIGNATURE_ERROR](#)

37.10.59.8 INVALID_TRAFFIC_LIMIT

Explanation: This error indicates that the attempted update of the extra traffic limits for a particular member failed because the new limit is lower than the current limit.

Resolution: Extra traffic limits can only be increased. Submit the topology transaction with a higher limit. The metadata details of this error contain the expected minimum value in the field `expectedMinimum`.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [INVALID_TRAFFIC_LIMIT](#)

37.10.59.9 NO_APPROPRIATE_SIGNING_KEY_IN_STORE

Explanation: This error results if the topology manager did not find a secret key in its store to authorize a certain topology transaction.

Resolution: Inspect your topology transaction and your secret key store and check that you have the appropriate certificates and keys to issue the desired topology transaction. If the list of candidates is empty, then you are missing the certificates.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [NO_APPROPRIATE_SIGNING_KEY_IN_STORE](#)

37.10.59.10 NO_CORRESPONDING_ACTIVE_TX_TO_REVOKE

Explanation: This error indicates that the attempt to add a removal transaction was rejected, as the mapping / element affecting the removal did not exist.

Resolution: Inspect the topology state and ensure the mapping and the element id of the active transaction you are trying to revoke matches your revocation arguments.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [NO_CORRESPONDING_ACTIVE_TX_TO_REVOKE](#)

37.10.59.11 PUBLIC_KEY_NOT_IN_STORE

Explanation: This error indicates that a command contained a fingerprint referring to a public key not being present in the public key store.

Resolution: Upload the public key to the public key store using `$node.keys.public.load()` before retrying.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [PUBLIC_KEY_NOT_IN_STORE](#)

37.10.59.12 REMOVING_KEY_DANGLING_TRANSACTIONS_MUST_BE_FORCED

Explanation: This error indicates that the attempted key removal would create dangling topology transactions, making the node unusable.

Resolution: Add the `force = true` flag to your command if you are really sure what you are doing.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [REMOVING_KEY_DANGLING_TRANSACTIONS_MUST_BE_FORCED](#)

37.10.59.13 REMOVING_LAST_KEY_MUST_BE_FORCED

Explanation: This error indicates that the attempted key removal would remove the last valid key of the given entity, making the node unusable.

Resolution: Add the `force = true` flag to your command if you are really sure what you are doing.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [REMOVING_LAST_KEY_MUST_BE_FORCED](#)

37.10.59.14 SECRET_KEY_NOT_IN_STORE

Explanation: This error indicates that the secret key with the respective fingerprint can not be found.

Resolution: Ensure you only use fingerprints of secret keys stored in your secret key store.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status FAILED_PRECONDITION` including a detailed error message.

Scaladocs: [MALICIOUS_OR_FAULTY_ONBOARDING_REQUEST](#)

37.10.60.4 PARTICIPANT_NOT_INITIALIZED

Explanation: This error is returned if a domain topology manager attempts to activate a participant without having all necessary data, such as keys or domain trust certificates.

Resolution: Register the necessary keys or trust certificates and try again.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [PARTICIPANT_NOT_INITIALIZED](#)

37.10.60.5 WRONG_DOMAIN

Explanation: This error is returned if a transaction restricted to a domain should be added to another domain.

Resolution: Recreate the content of the transaction with a correct domain identifier.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [WRONG_DOMAIN](#)

37.10.60.6 WRONG_PROTOCOL_VERSION

Explanation: This error is returned if a transaction has a protocol version different than the one spoken on the domain.

Resolution: Recreate the transaction with a correct protocol version.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [WRONG_PROTOCOL_VERSION](#)

37.10.61 5.1.2. ParticipantTopologyManagerError

37.10.61.1 CANNOT_VET_DUE_TO_MISSING_PACKAGES

Explanation: This error indicates that a package vetting command failed due to packages not existing locally. This can be due to either the packages not being present or their dependencies being missing. When vetting a package, the package must exist on the participant, as otherwise the participant will not be able to process a transaction relying on a particular package.

Resolution: Ensure that the package exists locally before issuing such a transaction.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [CANNOT_VET_DUE_TO_MISSING_PACKAGES](#)

37.10.61.2 DANGEROUS_KEY_USE_COMMAND_REQUIRES_FORCE

Explanation: This error indicates that a dangerous owner to key mapping authorization was rejected. This is the case if a command is run that could break a participant. If the command was run to assign a key for the given participant, then the command was rejected because the key is not in the participants private store. If the command is run on a participant to issue transactions for another participant, then such commands must be run with force, as they are very dangerous and could easily break the participant. As an example, if we assign an encryption key to a participant that the participant does not have, then the participant will be unable to process an incoming transaction. Therefore we must be very careful to not create such situations.

Resolution: Set force=true if you really know what you are doing.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DANGEROUS_KEY_USE_COMMAND_REQUIRES_FORCE](#)

37.10.61.3 DANGEROUS_VETTING_COMMANDS_REQUIRE_FORCE

Explanation: This error indicates that a dangerous package vetting command was rejected. This is the case if a vetting command, if not run correctly, could potentially lead to a ledger fork. The vetting authorization checks the participant for the presence of the given set of packages (including their dependencies) and allows only to vet for the given participant id. In rare cases where a more centralised topology manager is used, this behaviour can be overridden with force. However, if a package is vetted but not present on the participant, the participant will refuse to process any transaction of the given domain until the problematic package has been uploaded.

Resolution: Set force=true if you really know what you are doing.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DANGEROUS_VETTING_COMMANDS_REQUIRE_FORCE](#)

37.10.61.4 DEPENDENCIES_NOT_CHECK_ONLY_OR_VETTED

Explanation: This error indicates a packages topology request marking a set of packages as check-only failed due to dependencies not being marked as vetted or check-only. The system requires that not only the main packages are marked checked-only explicitly but also all dependencies must be declared as either vetted or check-only. This is necessary as not all participants are required to have the same packages installed and therefore not every participant can resolve the dependencies implicitly.

Resolution: Vet the dependencies first and then repeat your attempt.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DEPENDENCIES_NOT_CHECK_ONLY_OR_VETTED](#)

37.10.61.5 DEPENDENCIES_NOT_VETTED

Explanation: This error indicates a vetting request failed due to dependencies not being vetted. On every vetting request, the set supplied packages is analysed for dependencies. The system requires that not only the main packages are vetted explicitly but also all dependencies. This is necessary as not all participants are required to have the same packages installed and therefore not every participant can resolve the dependencies implicitly.

Resolution: Vet the dependencies first and then repeat your attempt.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DEPENDENCIES_NOT_VETTED](#)

37.10.61.6 DISABLE_PARTY_WITH_ACTIVE_CONTRACTS_REQUIRES_FORCE

Explanation: This error indicates that a dangerous PartyToParticipant mapping deletion was rejected. If the command is run and there are active contracts where the party is a stakeholder these contracts will become inoperable and will never get pruned, leaking storage.

Resolution: Set force=true if you really know what you are doing.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DISABLE_PARTY_WITH_ACTIVE_CONTRACTS_REQUIRES_FORCE](#)

37.10.61.7 MAIN_DAR_PACKAGE_REFERENCED_EXTERNALLY

Explanation: The operation has failed due to the DAR's main package being referenced in other uploaded and enabled DARs.

Resolution: First disable the other DARs or explicitly remove the offending topology transaction(s) referencing the main package. Then, re-try the operation.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [MAIN_DAR_PACKAGE_REFERENCED_EXTERNALLY](#)

37.10.61.8 PACKAGE_TOPOLOGY_STATE_UPDATE_TIMEOUT

Explanation: This error indicates that a package topology state update has timed out.

Resolution: Retry the operation or check that no concurrent operations have affected the awaited topology state.

Category: DeadlineExceededRequestStateUnknown

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status DEADLINE_EXCEEDED including a detailed error message.

Scaladocs: [PACKAGE_TOPOLOGY_STATE_UPDATE_TIMEOUT](#)

37.10.61.9 UNINITIALIZED_PARTICIPANT

Explanation: This error indicates that a request involving topology management was attempted on a participant that is not yet initialised. During initialisation, only namespace and identifier delegations can be managed.

Resolution: Initialise the participant and retry.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [UNINITIALIZED_PARTICIPANT](#)

37.10.62 5.1.3. Domain

37.10.62.1 DOMAIN_NODE_INITIALISATION_FAILED

Explanation: This error indicates that the initialisation of a domain node failed due to invalid arguments.

Resolution: Consult the error details.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DOMAIN_NODE_INITIALISATION_FAILED](#)

37.10.63 5.1.3.1. GrpcSequencerAuthenticationService

37.10.63.1 CLIENT_AUTHENTICATION_FAULTY

Explanation: This error indicates that a client failed to authenticate with the sequencer due to a reason possibly pointing out to faulty or malicious behaviour. The message is logged on the server in order to support an operator to provide explanations to clients struggling to connect.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [CLIENT_AUTHENTICATION_FAULTY](#)

37.10.63.2 CLIENT_AUTHENTICATION_REJECTED

Explanation: This error indicates that a client failed to authenticate with the sequencer. The message is logged on the server in order to support an operator to provide explanations to clients struggling to connect.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side.

Scaladocs: [CLIENT_AUTHENTICATION_REJECTED](#)

37.10.64 5.2. DomainTopologySender

37.10.64.1 TOPOLOGY_DISPATCHING_DEGRADATION

Explanation: This warning occurs when the topology dispatcher experiences timeouts while trying to register topology transactions.

Resolution: This error should normally self-recover due to retries. If issue persists, contact support and investigate system state.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [TOPOLOGY_DISPATCHING_DEGRADATION](#)

37.10.64.2 TOPOLOGY_DISPATCHING_INTERNAL_ERROR

Explanation: This error is emitted if there is a fundamental, un-expected situation during topology dispatching. In such a situation, the topology state of a newly onboarded participant or of all domain members might become outdated

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [TOPOLOGY_DISPATCHING_INTERNAL_ERROR](#)

37.10.65 6. ConfigErrors

37.10.65.1 CANNOT_PARSE_CONFIG_FILES

Explanation: This error is usually thrown because a config file doesn't contain configs in valid HOCON format. The most common cause of an invalid HOCON format is a forgotten bracket.

Resolution: Make sure that all files are in valid HOCON format.

Category: InvalidIndependentOfSystemState

Conveyance: Config errors are logged and output to stdout if starting Canton with a given configuration fails

Scaladocs: [CANNOT_PARSE_CONFIG_FILES](#)

37.10.65.2 CANNOT_READ_CONFIG_FILES

Explanation: This error is usually thrown when Canton can't find a given configuration file.

Resolution: Make sure that the path and name of all configuration files is correctly specified.

Category: InvalidIndependentOfSystemState

Conveyance: Config errors are logged and output to stdout if starting Canton with a given configuration fails

Scaladocs: [CANNOT_READ_CONFIG_FILES](#)

37.10.65.3 CONFIG_SUBSTITUTION_ERROR

Resolution: A common cause of this error is attempting to use an environment variable that isn't defined within a config-file.

Category: InvalidIndependentOfSystemState

Conveyance: Config errors are logged and output to stdout if starting Canton with a given configuration fails

Scaladocs: [CONFIG_SUBSTITUTION_ERROR](#)

37.10.65.4 CONFIG_VALIDATION_ERROR

Category: InvalidIndependentOfSystemState

Conveyance: Config errors are logged and output to stdout if starting Canton with a given configuration fails

Scaladocs: [CONFIG_VALIDATION_ERROR](#)

37.10.65.5 GENERIC_CONFIG_ERROR

Resolution: In general, this can be one of many errors since this is the 'miscellaneous category' of configuration errors. One of the more common errors in this category is an 'unknown key' error. This error usually means that a keyword that is not valid (e.g. it may have a typo 'bort' instead of 'port'), or that a valid keyword at the wrong part of the configuration hierarchy was used (e.g. to enable database replication for a participant, the correct configuration is `canton.participants.participant2.replication.enabled = true` and not `canton.participants.replication.enabled = true`). Please refer to the scaladoc of either `CantonEnterpriseConfig` or `CantonCommunityConfig` (depending on whether the community or enterprise version is used) to find the valid configuration keywords and the correct position in the configuration hierarchy.

Category: InvalidIndependentOfSystemState

Conveyance: Config errors are logged and output to stdout if starting Canton with a given configuration fails

Scaladocs: [GENERIC_CONFIG_ERROR](#)

37.10.65.6 NO_CONFIG_FILES

Category: InvalidIndependentOfSystemState

Conveyance: Config errors are logged and output to stdout if starting Canton with a given configuration fails

Scaladocs: [NO_CONFIG_FILES](#)

37.10.66 7. CommandErrors

37.10.66.1 CONSOLE_COMMAND_INTERNAL_ERROR

Category: SystemInternalAssumptionViolated

Conveyance: These errors are shown as errors on the console.

Scaladocs: [CONSOLE_COMMAND_INTERNAL_ERROR](#)

37.10.66.2 `CONSOLE_COMMAND_TIMED_OUT`

Category: `SystemInternalAssumptionViolated`

Conveyance: These errors are shown as errors on the console.

Scaladocs: [CONSOLE_COMMAND_TIMED_OUT](#)

37.10.66.3 `NODE_NOT_STARTED`

Category: `InvalidGivenCurrentSystemStateOther`

Conveyance: These errors are shown as errors on the console.

Scaladocs: [NODE_NOT_STARTED](#)

37.10.67 8. `DatabaseStorageError`

37.10.67.1 `DB_CONNECTION_LOST`

Explanation: This error indicates that the connection to the database has been lost.

Resolution: Inspect error message for details.

Category: `BackgroundProcessDegradationWarning`

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [DB_CONNECTION_LOST](#)

37.10.67.2 `DB_STORAGE_DEGRADATION`

Explanation: This error indicates that degradation of database storage components.

Resolution: This error indicates performance degradation. The error occurs when a database task has been rejected, typically due to having a too small task queue. The task will be retried after a delay. If this error occurs frequently, however, you may want to consider increasing the task queue. (Config parameter: `canton.<path-to-my-node>.storage.config.queueSize`).

Category: `BackgroundProcessDegradationWarning`

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [DB_STORAGE_DEGRADATION](#)

37.10.68 9. `HandshakeErrors`

37.10.68.1 `DEPRECATED_PROTOCOL_VERSION`

Explanation: This error is logged or returned if a participant or domain are using deprecated protocol versions. Deprecated protocol versions might not be secure anymore.

Resolution: Migrate to a new domain that uses the most recent protocol version.

Category: `SecurityAlert`

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with `grpc-status INVALID_ARGUMENT` without any details for security reasons.

Scaladocs: [DEPRECATED_PROTOCOL_VERSION](#)

37.10.68.2 DEPRECATING_PROTOCOL_VERSION

Explanation: This error is logged or returned if a participant or domain are using a protocol versions which will be deprecated.

Resolution: Consider migration to a new domain that uses the most recent protocol version.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [DEPRECATING_PROTOCOL_VERSION](#)

37.10.69 10. EnvelopeOpenerError

37.10.69.1 EVENT_DESERIALIZATION_ERROR

Explanation: This error indicates that the sequencer client was unable to parse a message. This indicates that the message has been created by a bogus or malicious sender. The message will be dropped.

Resolution: If no other errors are reported, Canton has recovered automatically. You should still consider to start an investigation to understand why the sender has sent an invalid message.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [EVENT_DESERIALIZATION_ERROR](#)

37.10.70 11. FabricErrors

37.10.71 11.1. ConfigurationErrors

37.10.71.1 FABRIC_AHEAD_OF_HEAD

Explanation: This warning is logged on startup if the sequencer is configured to only start reading from a block that wasn't ordered yet by the blockchain (e.g. sequencer is supposed to start reading from block 500, but the latest block is only 100). This is likely due to a misconfiguration.

Resolution: This issue frequently occurs when the blockchain is reset but the sequencer database configuration is not updated or the sequencer database (which persists the last block that was read by the sequencer) is not reset. Validate these settings and ensure that the sequencer is still reading from the same blockchain.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [FABRIC_AHEAD_OF_HEAD](#)

37.10.71.2 FABRIC_MANY_BLOCKS_BEHIND_HEAD

Explanation: This error is logged when the sequencer is currently processing blocks that are very far behind the head of the blockchain of the connected Fabric network. The Fabric sequencer won't observe new transactions in the blockchain until it has caught up to the head. This may take a long time depending on the blockchain length and number of Canton transaction in the blocks. Empirically, we have observed that the Canton sequencer processes roughly 500 empty blocks/second. This may vary strongly for non-empty blocks.

Resolution: Change the configuration of `startBlockHeight` for the Fabric sequencer when working with an existing (not fresh) Fabric network. Alternatively, wait until the sequencer has caught up to the head of the blockchain.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [FABRIC_MANY_BLOCKS_BEHIND_HEAD](#)

37.10.72 11.2. TransactionErrors

37.10.72.1 FABRIC_TRANSACTION_INVALID

Explanation: This error happens when the Sequencer Fabric application reads a transaction from the blockchain which is malformed (e.g. missing arguments, arguments aren't parseable or too large). This could happen if a malicious or faulty Fabric Sequencer node is placing faulty data on the blockchain.

Resolution: Generally, Canton should recover automatically from this error. The faulty transactions are simply skipped by all non-malicious/non-faulty sequencers in a deterministic way, so the integrity of the event stream across sequencer nodes should be maintained. If you continue to see this error, investigate whether some of the sequencer nodes in the network are misbehaving.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with `grpc-status INVALID_ARGUMENT` without any details for security reasons.

Scaladocs: [FABRIC_TRANSACTION_INVALID](#)

37.10.72.2 FABRIC_TRANSACTION_PROPOSAL_SUBMISSION_FAILED

Explanation: An error happened with the Fabric transaction proposal submissions possibly due to some of the peers being down or due to network issues. Thus won't stop the transaction workflow, because there might still be enough successful responses to satisfy the endorsement policy. Therefore the transaction might still go through successfully despite this being logged.

Resolution: Generally, Canton should recover automatically from this error. If you continue to see this error, investigate possible root causes such as poor network connections, if the Fabric sequencer is properly configured with enough peers and if they are running.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with `grpc-status UNAVAILABLE` including a detailed error message.

Scaladocs: [FABRIC_TRANSACTION_PROPOSAL_SUBMISSION_FAILED](#)

37.10.72.3 FABRIC_TRANSACTION_SUBMISSION_FAILED

Explanation: This error is logged when the Sequencer Fabric application receives an error during any of the transaction flow steps that prevents the submission of a transaction over the Fabric client. Common causes for this are network errors, peers that are down or that there aren't enough configured endorsers.

Resolution: Generally, Canton should recover automatically from this error. If you continue to see this error, investigate possible root causes such as poor network connections, if the Fabric sequencer is properly configured with enough peers and if they are running.

Category: TransientServerFailure

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status UNAVAILABLE including a detailed error message.

Scaladocs: [FABRIC_TRANSACTION_SUBMISSION_FAILED](#)

37.10.73 12. SequencerError

37.10.73.1 INVALID_ACKNOWLEDGEMENT_SIGNATURE

Explanation: This error indicates that the sequencer has detected an invalid acknowledgement request signature. This most likely indicates that the request is bogus and has been created by a malicious sequencer. So it will not get processed.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_ACKNOWLEDGEMENT_SIGNATURE](#)

37.10.73.2 INVALID_ACKNOWLEDGEMENT_TIMESTAMP

Explanation: This error indicates that the member has acknowledged a timestamp that is after the events it has received. This violates the sequencing protocol.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_ACKNOWLEDGEMENT_TIMESTAMP](#)

37.10.73.3 INVALID_ENVELOPE_SIGNATURE

Explanation: This error indicates that the sequencer has detected an invalid envelope signature in the submission request. This most likely indicates that the request is bogus and has been created by a malicious sequencer. So it will not get processed.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_ENVELOPE_SIGNATURE](#)

37.10.73.4 INVALID_LEDGER_EVENT

Explanation: The sequencer has detected that some event that was placed on the ledger cannot be parsed. This may be due to some sequencer node acting maliciously or faulty. The event is ignored and processing continues as usual.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_LEDGER_EVENT](#)

37.10.73.5 INVALID_SEQUENCER_PRUNING_REQUEST_ON_CHAIN

Explanation: This error indicates that some sequencer node has distributed an invalid sequencer pruning request via the blockchain. Either the sequencer nodes got out of sync or one of the sequencer nodes is buggy. The sequencer node will stop processing to prevent the danger of severe data corruption.

Resolution: Stop using the domain involving the sequencer nodes. Contact support.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_SEQUENCER_PRUNING_REQUEST_ON_CHAIN](#)

37.10.73.6 INVALID_SUBMISSION_REQUEST_SIGNATURE

Explanation: This error indicates that the sequencer has detected an invalid submission request signature. This most likely indicates that the request is bogus and has been created by a malicious sequencer. So it will not get processed.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [INVALID_SUBMISSION_REQUEST_SIGNATURE](#)

37.10.73.7 MAX_REQUEST_SIZE_EXCEEDED

Explanation: This error means that the request size has exceeded the configured value maxRequestSize.

Resolution: Send smaller requests or increase the maxRequestSize in the domain parameters

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [MAX_REQUEST_SIZE_EXCEEDED](#)

37.10.73.8 MAX_SEQUENCING_TIME_EXCEEDED

Explanation: This error indicates that a request was not sequenced because the sequencing time would exceed the max-sequencing-time of the request. This error usually happens if either a participant or mediator node is too slowly responding to requests, or if it is catching up after some downtime. In rare cases, it can happen if the sequencer nodes are massively overloaded. If it happens repeatedly, this information might indicate that there is a problem with the respective participant or mediator node.

Resolution: Inspect the time difference between sequenced and max-sequencing-time. If the time difference is large, then some remote node is catching up but sending messages during catch-up. If the difference is not too large, then the submitting node or this sequencer node might be overloaded.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side.

Scaladocs: [MAX_SEQUENCING_TIME_EXCEEDED](#)

37.10.73.9 MISSING_SUBMISSION_REQUEST_SIGNATURE_TIMESTAMP

Explanation: This error indicates that the sequencer has detected that the signed submission request being processed is missing a signature timestamp. It indicates that the sequencer node that placed the request is not following the protocol as there should always be a defined timestamp. This request will not get processed.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [MISSING_SUBMISSION_REQUEST_SIGNATURE_TIMESTAMP](#)

37.10.73.10 MULTIPLE_MEDIATOR_RECIPIENTS

Explanation: This error indicates that the participant is trying to send envelopes to multiple mediators or mediator groups in the same submission request. This most likely indicates that the request is bogus and has been created by a malicious sequencer. So it will not get processed.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [MULTIPLE_MEDIATOR_RECIPIENTS](#)

37.10.73.11 PAYLOAD_TO_EVENT_TIME_BOUND_EXCEEDED

Explanation: This warning indicates that the time difference between storing the payload and writing the event exceeded the configured time bound, which resulted in the message to be discarded. This can happen during some failure event on the database which causes unexpected delay between these two database operations. (The two events need to be sufficiently close together to support pruning of payloads by timestamp).

Resolution: The submitting node will usually retry the command, but you should check the health of the sequencer node, in particular with respect to database processing.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [PAYLOAD_TO_EVENT_TIME_BOUND_EXCEEDED](#)

37.10.74 13. EnterpriseGrpcVaultServiceError

37.10.74.1 INVALID_KMS_KEY_ID

Explanation: Selected KMS key id is invalid

Resolution: Specify a valid key id and retry.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [INVALID_KMS_KEY_ID](#)

37.10.74.2 NO_ENCRYPTED_PRIVATE_KEY_STORE_ERROR

Explanation: Node is not running an encrypted private store

Resolution: Verify that an encrypted store and KMS config are set for this node.

Category: InternalUnsupportedOperation

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status UNIMPLEMENTED without any details for security reasons.

Scaladocs: [NO_ENCRYPTED_PRIVATE_KEY_STORE_ERROR](#)

37.10.74.3 REGISTER_KMS_KEY_INTERNAL_ERROR

Explanation: Internal error emitted upon failing to register a KMS key in Canton

Resolution: Contact support

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [REGISTER_KMS_KEY_INTERNAL_ERROR](#)

37.10.74.4 WRAPPER_KEY_ALREADY_IN_USE_ERROR

Explanation: Selected wrapper key id for rotation is already in use

Resolution: Select a different key id and retry.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [WRAPPER_KEY_ALREADY_IN_USE_ERROR](#)

37.10.74.5 WRAPPER_KEY_DISABLED_OR_DELETED_ERROR

Explanation: Selected wrapper key id for rotation cannot be used because key is disabled or set to be deleted

Resolution: Specify a key id from an active key and retry.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [WRAPPER_KEY_DISABLED_OR_DELETED_ERROR](#)

37.10.74.6 WRAPPER_KEY_NOT_EXIST_ERROR

Explanation: Selected wrapper key id for rotation does not match any existing KMS key

Resolution: Specify a key id that matches an existing KMS key and retry.

Category: InvalidGivenCurrentSystemStateResourceMissing

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status NOT_FOUND including a detailed error message.

Scaladocs: [WRAPPER_KEY_NOT_EXIST_ERROR](#)

37.10.74.7 WRAPPER_KEY_ROTATION_INTERNAL_ERROR

Explanation: Internal error emitted upon internal wrapper key rotation errors

Resolution: Contact support

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [WRAPPER_KEY_ROTATION_INTERNAL_ERROR](#)

37.10.75 14. MediatorError

37.10.75.1 MEDIATOR_INTERNAL_ERROR

Explanation: Request processing failed due to a violation of internal invariants. It indicates a bug at the mediator.

Resolution: Contact support.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [MEDIATOR_INTERNAL_ERROR](#)

37.10.75.2 MEDIATOR_INVALID_MESSAGE

Explanation: The mediator has received an invalid message (request or response). The message will be discarded. As a consequence, the underlying request may be rejected. No corruption of the ledger is to be expected. This error is to be expected after a restart or failover of a mediator.

Resolution: Address the cause of the error. Let the submitter retry the command.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level WARN on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [MEDIATOR_INVALID_MESSAGE](#)

37.10.75.3 MEDIATOR_RECEIVED_MALFORMED_MESSAGE

Explanation: The mediator has received a malformed message. This may occur due to a bug at the sender of the message. The message will be discarded. As a consequence, the underlying request may be rejected. No corruption of the ledger is to be expected.

Resolution: Contact support.

Category: SecurityAlert

Conveyance: This error is logged with log-level WARN on the server side. It is exposed on the API with grpc-status INVALID_ARGUMENT without any details for security reasons.

Scaladocs: [MEDIATOR_RECEIVED_MALFORMED_MESSAGE](#)

37.10.75.4 MEDIATOR_SAYS_TX_TIMED_OUT

Explanation: This rejection indicates that the transaction has been rejected by the mediator as it didn't receive enough confirmations within the participant response timeout. The field `unresponsiveParties` in the error info contains the comma-separated list of parties that failed to send a response within the participant response timeout. This field is only present since protocol version 6

Resolution: Check that all involved participants are available and not overloaded.

Category: ContentionOnSharedResources

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status ABORTED including a detailed error message.

Scaladocs: [MEDIATOR_SAYS_TX_TIMED_OUT](#)

37.10.76 15. ProtoDeserializationError

37.10.76.1 PROTO_DESERIALIZATION_FAILURE

Resolution: Inspect the error details and correct your application

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [PROTO_DESERIALIZATION_FAILURE](#)

37.10.77 16. SequencerErrors

37.10.77.1 SEQUENCER_AGGREGATE_SUBMISSION_ALREADY_SENT

Explanation: This error occurs when the sequencer has already sent out the aggregate submission for the request.

Resolution: This is expected to happen during operation of a system with aggregate submissions enabled. No action required.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_AGGREGATE_SUBMISSION_ALREADY_SENT](#)

37.10.77.2 SEQUENCER_AGGREGATE_SUBMISSION_STUFFING

Explanation: This error occurs when the sequencer already received the same submission request from the same sender.

Resolution: This error indicates that an aggregate submission has already been accepted by the sequencer and for some reason there is a repeated submission. This is likely caused by retrying a submission. This can usually be ignored.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_AGGREGATE_SUBMISSION_STUFFING](#)

37.10.77.3 SEQUENCER_MAX_SEQUENCING_TIME_TOO_FAR

Explanation: Maximum sequencing time on the submission request is exceeding the maximum allowed interval into the future. Could be result of a concurrent dynamic domain parameter change for sequencerAggregateSubmissionTimeout.

Resolution: In case there was a recent concurrent dynamic domain parameter change, simply retry the submission. Otherwise this error code indicates a bug in Canton (a faulty node behaviour). Please contact customer support.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_MAX_SEQUENCING_TIME_TOO_FAR](#)

37.10.77.4 SEQUENCER_NOT_ENOUGH_TRAFFIC_CREDIT

Explanation: Sequencer has refused a submission request due to insufficient credits in the sender's traffic balance.

Resolution: Acquire more traffic credits with the system by topping up traffic credits for the sender.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_NOT_ENOUGH_TRAFFIC_CREDIT](#)

37.10.77.5 SEQUENCER_SIGNING_TIMESTAMP_AFTER_SEQUENCING_TIMESTAMP

Explanation: Timestamp of the signing key on the submission request is later than the sequencing time.

Resolution: This indicates a bug in Canton (a faulty node behaviour). Please contact customer support.

Category: InvalidGivenCurrentSystemStateOther

Scaladocs: [SEQUENCER_SIGNING_TIMESTAMP_AFTER_SEQUENCING_TIMESTAMP](#)

37.10.77.6 SEQUENCER_SIGNING_TIMESTAMP_MISSING

Explanation: Timestamp of the signing key is missing on the submission request.

Resolution: This indicates a bug in Canton (a faulty node behaviour). Please contact customer support.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_SIGNING_TIMESTAMP_MISSING](#)

37.10.77.7 SEQUENCER_SIGNING_TIMESTAMP_TOO_EARLY

Explanation: Timestamp of the signing key on the submission request is earlier than allowed by the dynamic domain parameters.

Resolution: This indicates a bug in Canton (a faulty node behaviour). Please contact customer support.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_SIGNING_TIMESTAMP_TOO_EARLY](#)

37.10.77.8 SEQUENCER_SUBMISSION_REQUEST_MALFORMED

Explanation: This error occurs when the sequencer cannot parse the submission request.

Resolution: This usually indicates a misconfiguration of the system components or an application bug and requires operator intervention.

Category: InvalidIndependentOfSystemState

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status INVALID_ARGUMENT including a detailed error message.

Scaladocs: [SEQUENCER_SUBMISSION_REQUEST_MALFORMED](#)

37.10.77.9 SEQUENCER_SUBMISSION_REQUEST_REFUSED

Explanation: This error occurs when the sequencer cannot accept submission request due to the current state of the system.

Resolution: This usually indicates a misconfiguration of the system components or an application bug and requires operator intervention. Please refer to a specific error message to understand the exact cause.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_SUBMISSION_REQUEST_REFUSED](#)

37.10.77.10 SEQUENCER_TOMBSTONE_PERSISTED

Explanation: An onboarded sequencer has put a tombstone in place of an event with a timestamp older than the sequencer signing key.

Resolution: Clients should connect to another sequencer with older event history to consume the tombstoned events before reconnecting to the recently onboarded sequencer.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_TOMBSTONE_PERSISTED](#)

37.10.77.11 SEQUENCER_UNKNOWN_RECIPIENTS

Explanation: This error happens when a submission request specifies nodes that are not known to the sequencer.

Resolution: This indicates a bug in Canton (a faulty node behaviour). Please contact customer support.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_UNKNOWN_RECIPIENTS](#)

37.10.78 17. ResilientSequencerSubscription

37.10.78.1 SEQUENCER_FORK_DETECTED

Explanation: This error is logged when a sequencer client determined a ledger fork, where a sequencer node responded with different events for the same timestamp / counter. Whenever a client reconnects to a domain, it will start with the last message received and compare whether that last message matches the one it received previously. If not, it will report with this error. A ledger fork should not happen in normal operation. It can happen if the backups have been taken in a wrong order and e.g. the participant was more advanced than the sequencer.

Resolution: You can recover by restoring the system with a correctly ordered backup. Please consult the respective sections in the manual.

Category: SystemInternalAssumptionViolated

Conveyance: This error is logged with log-level ERROR on the server side. It is exposed on the API with grpc-status INTERNAL without any details for security reasons.

Scaladocs: [SEQUENCER_FORK_DETECTED](#)

37.10.78.2 SEQUENCER_SUBSCRIPTION_LOST

Explanation: This warning is logged when a sequencer subscription is interrupted. The system will keep on retrying to reconnect indefinitely.

Resolution: Monitor the situation and contact the server operator if the issues does not resolve itself automatically.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [SEQUENCER_SUBSCRIPTION_LOST](#)

37.10.79 18. SequencerSubscriptionError

37.10.79.1 SEQUENCER_TOMBSTONE_ENCOUNTERED

Explanation: This error indicates that a sequencer subscription to a recently onboarded sequencer attempted to read an event replaced with a tombstone. A tombstone occurs if the timestamp associated with the event predates the validity of the sequencer's signing key. This error results in the sequencer client disconnecting from the sequencer.

Resolution: Connect to another sequencer with older event history to consume the tombstoned events before reconnecting to the recently onboarded sequencer.

Category: InvalidGivenCurrentSystemStateOther

Conveyance: This error is logged with log-level INFO on the server side and exposed on the API with grpc-status FAILED_PRECONDITION including a detailed error message.

Scaladocs: [SEQUENCER_TOMBSTONE_ENCOUNTERED](#)

37.10.80 19. Clock

37.10.80.1 SYSTEM_CLOCK_RUNNING_BACKWARDS

Explanation: This error is emitted if the unique time generation detects that the host system clock is lagging behind the unique time source by more than a second. This can occur if the system processes more than 2e6 events per second (unlikely) or when the underlying host system clock is running backwards.

Resolution: Inspect your host system. Generally, the unique time source is not negatively affected by a clock moving backwards and will keep functioning. Therefore, this message is just a warning about something strange being detected.

Category: BackgroundProcessDegradationWarning

Conveyance: This error is logged with log-level WARN on the server side.

Scaladocs: [SYSTEM_CLOCK_RUNNING_BACKWARDS](#)

Chapter 38

Troubleshooting

38.1 Error: “<X> is not authorized to commit an update”

This error occurs when there are multiple obligables on a contract.

A cornerstone of Daml is that you cannot create a contract that will force some other party (or parties) into an obligation. This error means that a party is trying to do something that would force another parties into an agreement without their consent.

To solve this, make sure each party is entering into the contract freely by exercising a choice. A good way of ensuring this is the `initial` and `accept` pattern: see the Daml patterns for more details.

38.2 Error: “Argument is not of serializable type”

This error occurs when you’re using a function as a parameter to a template. For example, here is a contract that creates a `Payout` controller by a receiver’s supervisor:

```
template SupervisedPayout
  with
    supervisor : Party -> Party
    receiver   : Party
    giver      : Party
    amount     : Decimal
  where
    signatory giver
    observer (supervisor receiver)
    choice SupervisedPayout_Call
      : ContractId Payout
    controller supervisor receiver
    do create Payout with giver; receiver; amount
```

Hovering over the compilation error displays:

```
[Type checker] Argument expands to non-serializable type Party -> Party.
```

38.3 Error: “Recursion limit overflow in module”

The error usually occurs when uploading a DAR to a ledger or using a script via the sandbox. It can manifest on upload as:

```
upload-dar did not succeed: DAR_PARSE_ERROR(8,b5935497): Failed to parse the dar
↳ file content.
```

or in your logs as:

```
Recursion limit overflow in module '<pkgid>:<modulename>'
```

This error is usually caused by having an expression in the DAR whose serialized representation exceeds a depth of 1000 layers. This can be caused by long Daml scripts, since every use of a function call or `<-` to bind a variable in a `do` block can incur several layers of recursion in the `do` block's serialized representation. Large datatypes with more than 160 fields with deriving clauses can also cause this.

38.3.1 Solving script recursion limits

Normally, one call inside `do` introduces 4 layers of recursion, meaning about 250 binds in a script can cause an overflow. However, other expressions in a `do` block, such as `let` binds, also introduce a layer of recursion, so functions with fewer binds can also trigger the limit.

Possible workarounds include splitting a large script into multiple scripts or separating logic in the script out into helper functions. For example, assume you have written the following long script:

```
data State = State { partA : Text, partB : Text, partC : Text }

-- MyTemplate defines three choices that update parts A, B, and C of the State
myScript : Party -> ContractId MyTemplate -> State -> Script State
myScript party cid state0 = do
  newPartA <- party `submit` exerciseCmd cid (UpdateStatePartA state0)
  newPartB <- party `submit` exerciseCmd cid (UpdateStatePartB state0)
  newPartC <- party `submit` exerciseCmd cid (UpdateStatePartC state0)
  let state1 = State newPartA newPartB newPartC

  newPartA <- party `submit` exerciseCmd cid (UpdateStatePartA state1)
  newPartB <- party `submit` exerciseCmd cid (UpdateStatePartB state1)
  newPartC <- party `submit` exerciseCmd cid (UpdateStatePartC state1)
  let state2 = State newPartA newPartB newPartC

  ...
  newPartA <- party `submit` exerciseCmd cid (UpdateStatePartA state99)
  newPartB <- party `submit` exerciseCmd cid (UpdateStatePartB state99)
  newPartC <- party `submit` exerciseCmd cid (UpdateStatePartC state99)
  let state100 = State newPartA newPartB newPartC

  pure state100
```

This script has 300 binds, well exceeding the tentative limit of 250 binds. We can refactor this script to instead define and use a helper `updateStateOnce`, which runs all three choices together.

Note: In many cases, the compiler optimizes your script to produce an expression that does not break the recursion limit despite having many binds. In this example, we have given an intentionally

convoluted example that is difficult for the compiler to optimize away.

By using this helper, each block of three exercises is reduced to a single bind, such that `myScript` now has only 100 binds, well below the recursion limit.

```
data State = State { partA : Text, partB : Text, partC : Text }
  deriving (Show, Eq)

helper : Party -> ContractId MyTemplate -> State -> Script State
helper party cid state = do
  newPartA <- party `submit` exerciseCmd cid (UpdateStatePartA state.partA)
  newPartB <- party `submit` exerciseCmd cid (UpdateStatePartB state.partB)
  newPartC <- party `submit` exerciseCmd cid (UpdateStatePartC state.partC)
  pure (State newPartA newPartB newPartC)

myScript : Party -> ContractId MyTemplate -> State -> Script State
myScript party cid state0 = do
  state1 <- helper party cid state0
  state2 <- helper party cid state1
  ...
  state100 <- helper party cid state99

  pure state100
```

In general, it is a good idea to keep your scripts small, by maximizing code reuse and splitting logic into maintainable chunks.

38.3.2 Solving datatype recursion limits

Large datatypes with deriving clauses can also cause overflow errors. Consider the following case of a datatype with 300 fields and a deriving `Show` instance:

```
data MyData = MyData
{ field1A : Text
, field1B : Text
, field1C : Text
, field2A : Text
, field2B : Text
, field2C : Text
...
, field100A : Text
, field100B : Text
, field100C : Text
}
  deriving Show
```

In this case, the deriving `Show` clause means that instance of `Show MyData` is automatically derived to be something like the following:

```
-- Something similar to this code is implicitly autogenerated by the `deriving
↳ Show` clause
instance Show MyData where
  show MyData {...} =
    show field1A <> (show field1B <> (show field1C <> (
      (show field2A <> (show field2B <> (show field2C <> (
```

(continues on next page)

(continued from previous page)

```
...
(show field100A <> (show field100B <> (show field100C)))
)))
)))
```

You can see that the implicit, autogenerated definition of `show` has an expression that becomes more and more deeply nested as you go along. Once the number of fields exceeds about 160, this expression has the potential to reach the depth necessary to cause an overflow in its serialized representation in the DAR.

Similarly to Daml Scripts, the recommended workaround for this issue is to split your datatype into many parts. For example, we could create an additional datatype `Helper` which contains the elements `a`, `b`, and `c`, and use that within `MyData`:

```
data Helper = Helper
{ a : Text
, b : Text
, c : Text
}
deriving Show

data MyData = MyData
{ field1 : Helper
, field2 : Helper
...
, field100 : Helper
}
deriving Show
```

The generated code for `MyData` now has only 100 fields to traverse and nest. Similarly to scripts, it is a good idea to keep your datatypes small, by maximizing code reuse and splitting logic into maintainable chunks.

38.4 Modeling Questions

38.4.1 How To Model an Agreement With Another Party

To enter into an agreement, create a contract from a template that has explicit `signatory` and `agreement` statements.

You'll need to use a series of contracts that give each party the chance to consent, via a contract choice.

Because of the rules that Daml enforces, it is not possible for a single party to create an instance of a multi-party agreement. This is because such a creation would force the other parties into that agreement, without giving them a choice to enter it or not.

38.4.2 How To Model Rights

Use a contract choice to model a right. A party exercises that right by exercising the choice.

38.4.3 How To Void a Contract

To allow voiding a contract, provide a choice that does not create any new contracts. Daml contracts are archived (but not deleted) when a consuming choice is made - so exercising the choice effectively voids the contract.

However, you should bear in mind who is allowed to void a contract, especially without the re-sought consent of the other signatories.

38.4.4 How To Represent Off-ledger Parties

You'd need to do this if you can't set up all parties as ledger participants, because the Daml `Party` type gets associated with a cryptographic key and can so only be used with parties that have been set up accordingly.

To model off-ledger parties in Daml, they must be represented on-ledger by a participant who can sign on their behalf. You could represent them with an ordinary `Text` argument.

This isn't very private, so you could use a numeric ID/an `accountId` to identify the off-ledger client.

38.4.5 How To Limit a Choice by Time

Some rights have a time limit: either a time by which it must be exercised or a time before which it cannot be exercised.

You can use `getTime` to get the current time, and compare your desired time to it. Use `assert` to abort the choice if your time condition is not met.

38.4.6 How To Model a Mandatory Action

If you want to ensure that a party takes some action within a given time period. Might want to incur a penalty if they don't - because that would breach the contract.

For example: an Invoice that must be paid by a certain date, with a penalty (could be something like an added interest charge or a penalty fee). To do this, you could have a time-limited `Penalty` choice that can only be exercised after the time period has expired.

However, note that the penalty action can only ever create another contract on the ledger, which represents an agreement between all parties that the initial contract has been breached. Ultimately, the recourse for any breach is legal action of some kind. What Daml provides is provable violation of the agreement.

38.4.7 When to Use Optional

The `Optional` type, from the standard library, to indicate that a value is optional, i.e, that in some cases it may be missing.

In functional languages, `Optional` is a better way of indicating a missing value than using the more familiar value `NULL`, present in imperative languages like Java.

To use `Optional`, include `Optional.daml` from the standard library:

```
import DA.Optional
```

Then, you can create `Optional` values like this:

```
Some "Some text"      -- Optional value exists.
```

```
None                  -- Optional value does not exist.
```

You can test for existence in various ways:

```
-- isSome returns True if there is a value.
if isSome m
  then "Yes"
  else "No"
```

```
-- The inverse is isNone.
if isNone m
  then "No"
  else "Yes"
```

If you need to extract the value, use the `optional` function.

It returns a value of a defined type, and takes a `Optional` value and a function that can transform the value contained in a `Some` value of the `Optional` to that type. If it is missing `optional` also takes a value of the return type (the default value), which will be returned if the `Optional` value is `None`

```
let f = \ (i : Int) -> "The number is " <> (show i)
let t = optional "No number" f someValue
```

If `optionalValue` is `Some 5`, the value of `t` would be `"The number is 5"`. If it was `None`, `t` would be `"No number"`. Note that with `optional`, it is possible to return a different type from that contained in the `Optional` value. This makes the `Optional` type very flexible.

There are many other functions in `Optional.daml` that let you perform familiar functional operations on structures that contain `Optional` values – such as `map`, `filter`, etc. on `Lists` of `Optional` values.

38.5 Testing Questions

38.5.1 How To Test That a Contract Is Visible to a Party

Use `queryContractId`: its first argument is a party, and the second is a `ContractId`. If the contract corresponding to that `ContractId` exists and is visible to the party, the result will be wrapped in `Some`, otherwise the result will be `None`.

Use a `submit` block and a `fetch` operation. The `submit` block tests that the contract (as a `ContractId`) is visible to that party, and the `fetch` tests that it is valid, i.e., that the contract does exist.

For example, if we wanted to test for the existence and visibility of an `Invoice`, visible to 'Alice', whose `ContractId` is bound to `invoiceCid`, we could say:

```
Some result <- alice `queryContractId` invoiceCid
```

Note that we pattern match on the `Some` constructor. If the contract doesn't exist or is not visible to 'Alice', the test will fail with a pattern match error.

Now that the contract is bound to a variable, we can check whether it has some expected values:

```
result === Invoice with
  payee = alice
  payer = acme
  amount = 130.0
  service = "A job well done"
  timeLimit = datetime 1970 Feb 20 0 0 0
```

38.5.2 How To Test That an Update Action Cannot Be Committed

Use the `submitMustFail` function. This is similar in form to the `submit` function, but is an assertion that an update will fail if attempted by some Party.

Chapter 39

Get Help

Have questions or feedback? You're in the right place.

Questions: Forum

For `how do I?` , `why does something work this way` or `I've got a programming problem I'm trying to solve` questions, the `Questions` category [on our forum](#) is the best place to ask. If you're not sure what makes a good question, take a look at [our guide on the topic](#).

Feedback: Forum

If you want to give feedback, you can make a topic in the `General` category [on our forum](#).

When you're in the community Forum or on Stack Overflow, please keep to our [Code of Conduct](#).

39.1 Support Expectations

For Daml Open Source users:

Timing: You can enjoy the support of the community, which is provided for you out of their own good will and free time. On top of that, a Digital Asset employee will try to reply to unanswered questions within two business days.

Business days are affected by public holidays. Engineers contributing to Daml are mostly located in Zurich and New York, so please be mindful of the public holidays in those locations ([timeanddate.com](#) maintains an unofficial list of holidays for both [Switzerland](#) and the [United States](#)).

Public support: We offer public support in the `Questions` category [on our forum](#).

We can't answer questions in private messages or over email, so please only ask questions in public forums.

Level of support: We're happy to answer questions about error messages you're encountering, or discuss Daml design questions. However, we can't provide more extensive consultation on how to build your Daml application or the languages, frameworks, libraries and tools you may use to build it.

Digital Asset offers paid private support, which can be accessed [here](#). Digital Asset further offers consultation on how to build your Daml application; please contact us for pricing.

Chapter 40

Portability, Compatibility, and Support Durations

The Daml Ecosystem offers a number of forward and backward compatibility guarantees aiming to give the Ecosystem as a whole the following properties. See [Architecture](#) for the terms used here and how they fit together.

Application Portability

A Daml application should not depend on the underlying Database or DLT used by a Daml network.

Network Upgradeability

Ledger Operators should be able to upgrade Daml network or Participant Nodes seamlessly to stay up to date with the latest features and fixes. A Daml application should be able to operate without significant change across such Network Upgrades.

Daml Upgradeability

Application Developers should be able to update their developer tools seamlessly to stay up to date with the latest features and fixes, and stay able to maintain and develop their existing applications.

40.1 Ledger API Compatibility: Application Portability

Application Portability and to some extent Network Upgradeability are achieved by intermediating through the Ledger API. As per [Versioning](#), and [Architecture](#), the Ledger API is independently semantically versioned, and the compatibility guarantees derived from that semantic versioning extend to the entire semantics of the API, including the behavior of Daml Packages on the Ledger. Since all interaction with a Daml Ledger happens through the Daml Ledger API, a Daml Application is guaranteed to work as long as the Participant Node exposes a compatible Ledger API version.

Specifically, if a Daml Application is built against Ledger API version X.Y.Z and a Participant Node exposes Ledger API version X.Y2.Z2, the application is guaranteed to work as long as $Y2.Z2 \geq Y.Z$.

Participant Nodes advertise the Ledger API version they support via the [version service](#).

As a concrete example, Daml for Postgres 1.4.0 has the Participant Node integrated, and exposes Ledger API version 1.4.0 and the Daml for VMware Blockchain 1.0 Participant Nodes expose Ledger API

version 1.6.0. So any application that runs on Daml for Postgres 1.4.0 will also run on Daml for VMware Blockchain 1.0.

40.1.1 List of Ledger API Versions Supported by Daml

The below lists with which Daml version a new Ledger API version was introduced.

Ledger API Version	Daml Version
2.9	2.9
2.5	2.8
2.4	2.7
2.3	2.6
2.2	2.5
2.1	2.4
2.0	2.0
1.12	1.15
1.11	1.14
1.10	1.11
1.9	1.10
1.8	1.9
<= 1.7	Introduced with the same Daml SDK version

40.1.2 Summary of Ledger API Changes

Ledger API Version	Changes
2.9	<p><i>ListKnownParties</i> in the <i>PartyManagementService</i> has been extended with paging support. The request contains an optional <i>page_token</i> and <i>page_size</i> fields and the response a <i>next_page_token</i> that allow chaining of the result pages.</p> <p>The support for paging and the default max page size is announced through the <i>features.party_management.max_parties_page_size</i> field inside of the <i>GetLedgerApiVersion</i> response.</p> <p>The <i>PackageManagementService</i> has been extended with a new <i>ValidateDarFile</i> call.</p> <p>The <i>Commands</i> message used in the <i>CommandService</i> and <i>CommandSubmissionService</i> has been extended with a <i>package_id_selection_preference</i> field.</p> <p>The <i>CreatedEvent</i> and <i>ExercisedEvent</i> messages used in the <i>TransactionService</i> and <i>EventQueryService</i> have been extended with a <i>package_name</i> field.</p> <p>The <i>GetTransactionsRequest</i> has been extended with a new <i>send_pruned_offsets</i> field and the <i>GetTransactionsResponse</i> with an optional <i>pruned_offset</i> field.</p> <p>The support for the pruning offset subscriptions is announced through the <i>features.experimental.pruned_offsets.supported</i> field inside of the <i>GetLedgerApiVersion</i> response.</p> <p>A new <i>CommandInspectionService</i> has been added to <i>v1/admin</i> portion of the ledger api grpc interface.</p> <p>The support for the command inspection service is announced through the <i>features.experimental.command_inspection_service.supported</i> field inside of the <i>GetLedgerApiVersion</i> response.</p>
2.5	<p>A <i>TraceContext</i> is returned in messages in response to <i>TransactionService.GetTransactions</i>, <i>TransactionService.GetTransactionTrees</i>, <i>TransactionService.GetTransactionByEventId</i>, <i>TransactionService.GetTransactionById</i>, <i>TransactionService.GetFlatTransactionByEventId</i>, <i>TransactionService.GetFlatTransactionById</i>, <i>CompletionService.CompletionStream</i> calls.</p>
1796	<p>Chapter 40. Portability, Compatibility, and Support Durations</p> <p>The <i>CreatedEvent</i> message has been extended with <i>created_event_blob</i> and <i>created_at</i> fields.</p> <p>The <i>DisclosedContract</i> message has been modified to contain <i>contract_id</i> and <i>contract_id</i>.</p>

40.2 Driver and Participant Compatibility: Network Upgradeability

Given the Ledger API Compatibility above, network upgrades are seamless if they preserve data, and Participant Nodes keep exposing the same or a newer minor version of the same major Ledger API Version. The semantic versioning of Daml drivers and participant nodes gives this guarantee. Upgrades from one minor version to another are data preserving, and major Ledger API versions may only be removed with a new major version of integration components, Daml drivers and Participant Nodes.

As an example, from an application standpoint, the only effect of upgrading Daml for Postgres 1.4.0 to Daml for Postgres 1.6.0 is an uptick in the Ledger API version. There may be significant changes to components or database schemas, but these are not public APIs.

40.2.1 Participant database migration

Participant Nodes automatically manage their database schema. The database schema is tied to the Daml version, and schema migrations are always data preserving. The below lists which Daml version can be upgraded from which Daml version.

Daml SDK version	Upgradeable from
2.1	1.7 or later
≤ 2.0	1.0 or later

As an example, to upgrade a Participant Node built with Daml 1.4.0 to a version built with Daml 2.1, the operator should first upgrade to Daml 1.7 (or any other version between 1.7 and 2.0), then upgrade to Daml 2.1.

40.3 SDK, Runtime Component, and Library Compatibility: Daml Upgradeability

As long as a major Ledger API version is supported (see [Ledger API Support Duration](#)), there will be supported version of Daml able to target all minor versions of that major version. This has the obvious caveat that new features may not be available with old Ledger API versions.

For example, an application built and compiled with Daml SDK 1.4.0 against Ledger API 1.4.0, it can still be compiled using SDK 1.6.0 and can be run against Ledger API 1.4.0 using 1.6.0 libraries and runtime components.

40.4 Ledger API Support Duration

Major Ledger API versions behave like stable features in [Status Definitions](#). They are supported from the time they are first released as `stable` to the point where they are removed from Integration Components and Daml following a 12 month deprecation cycle. The earliest point a major Ledger API version can be deprecated is with the release of the next major version. The earliest it can be removed is 12 months later with a major version release of the Integration Components.

Other than for hotfix releases, new releases of the Integration Components will only support the latest minor/patch version of each major Ledger API version.

As a result we can make this overall statement:

An application built using Daml SDK U.V.W against Ledger API X.Y.Z can be maintained using any Daml SDK version U2.V2.W2 \geq U.V.W as long as Ledger API major version X is still supported at the time of release of U2.V2.W2, and run against any Daml Network with Participant Nodes exposing Ledger API X.Y2.Z2 \geq X.Y.Z.

Chapter 41

Daml Ecosystem Overview

This page is intended to give you an overview of the components that constitute the Daml Ecosystem, what status they are in, and how they fit together. It lays out Daml's `public API` in the sense of [Semantic Versioning](#), and is a prerequisite to understanding Daml's [Portability, Compatibility, and Support Durations](#).

[Status Definitions](#) gives a fine-grained view of what labels like `Alpha` and `Beta` mean.

41.1 Architecture

A high-level view of the architecture of a Daml application or solution is helpful to make sense of how individual components, APIs and features fit into the Daml Stack.

The stack is segmented into two parts. Daml drivers encompass those components that enable an infrastructure to run Daml Smart Contracts, turning it into a **Daml Network**. **Daml Components** consists of everything developers and users need to connect to a Daml Network: the tools to build, deploy, integrate, and maintain a Daml Application.

Taking the diagram from left to right, the SDK acts on various components of the client application and directly on the participant nodes: it aids in the development of user code, generates code of its own, feeds into runtime components via runtime APIs, and creates participant nodes via the Ledger API. The client application also acts on participant nodes via the Ledger API, and the user code for that application can act on the various Daml components of the application (generated code, libraries, and runtime components) via public API. Participant nodes, in turn, act via an internal API on the Daml network, specifically with Daml drivers that in turn interact with infrastructure nodes. The infrastructure nodes can also interact with each other. Each client application is linked to only one participant node, but a participant node can potentially touch more than one Daml network.

41.2 Daml Networks

41.2.1 Daml drivers

At the bottom of every Daml application is a Daml network: a distributed, or possibly centralized persistence infrastructure together with Daml drivers. Daml drivers enable the persistence infrastructure to act as a consensus, messaging, and in some cases persistence layer for Daml applications. Most Daml drivers will have a public API, but there are no *uniform* public APIs on Daml drivers. This does not harm application portability since applications only interact with Daml networks through the participant node. A good example of a public API of a Daml driver is the deployment interface of [Daml for VMware Blockchain](#). It's a public interface, but specific to the VMware driver.

41.3 Participant Nodes

On top of, or integrated into the Daml drivers sits a participant node that has the primary purpose of exposing the Daml Ledger API. In the case of *integrated* Daml drivers, the participant node usually interacts with the Daml drivers through solution-specific APIs. In this case, participant nodes can only communicate with the Daml drivers of one Daml network. In the case of *interoperable* Daml drivers, the participant node communicates with the Daml drivers through the uniform Canton Protocol. The Canton Protocol is versioned and has some cross-version compatibility guarantees, but is not a public API. So participant nodes may have public APIs like monitoring and logging, command line interfaces or similar, but the only *uniform* public API exposed by all participant nodes is the Ledger API.

41.4 Ledger API

The Ledger API is the primary interface that offers forward and backward compatibility between Daml Networks and applications (including Daml components). As you can see in the diagram above, all interactions between components above the participant node and the participant node or Daml Network happen through the Ledger API. The Ledger API is a public API and offers the lowest level of access to Daml Ledgers supported for application use.

41.5 Daml Components

41.5.1 Runtime components

Runtime components are standalone components that run alongside participant nodes or applications and expose additional services like query endpoints, automations, or integrations. Each Runtime component has public APIs. Typically there is a command line interface, and one or more Runtime APIs as indicated in the above diagram.

41.5.2 Libraries

Libraries naturally provide public APIs in their target language, be it Daml or secondary languages like JavaScript or Java.

41.5.3 Generated code

The SDK allows the generation of code for some languages from a Daml Model. This generated code has public APIs, which are not independently versioned, but depend on the Daml version and source of the generated code, like a Daml package. In this case, the version of the Daml SDK used covers changes to the public API of the generated code.

41.5.4 Developer tools / SDK

The Daml SDK consists of the developer tools used to develop user code, both Daml and in secondary languages, to generate code, and to interact with running applications via Runtime and Ledger API. The SDK has a broad public API covering the Daml Language, CLIs, IDE, and Developer tools, but few of those APIs are intended for runtime use in a production environment.

41.6 Status Definitions

Throughout the documentation, we use labels to mark features of APIs not yet deemed stable. This page gives meaning to those labels.

41.6.1 Early Access Features

Features or components covered by these docs are [Stable](#) by default. [Stable](#) features and components constitute Daml's public API in the sense of [Semantic Versioning](#). Feature and components that are not [Stable](#) are called `Early Access` and called out explicitly.

Early Access features are opt-in whenever possible, needing to be activated with special commands or flags needing to be started up separately, or requiring the use of additional endpoints, for example.

Within the Early Access category, we distinguish three labels:

Labs

Labs components and features are experiments, introduced for evaluation, testing, or project-internal use. There is no intent to develop them into a stable feature other than to see whether they add value and find uptake. They can be changed or discontinued without advance notice. They may be poorly documented and it is not recommended to start relying on them.

Alpha

Alpha components and features are early preview versions of features being actively developed to become a stable part of the ecosystem. At the Alpha stage, they are not yet feature complete, may have poor runtime characteristics, are still subject to frequent change, and may not be fully documented. Alpha features can be evaluated, and used in PoCs, but should not yet be relied upon for large projects or production use where break-ages or changes to APIs would be costly.

Beta

Beta components and features are preview versions of features that are close to maturity. They are characterized by being considered feature complete, and the APIs close to the final public APIs. It is relatively safe to build on Beta features as long as the documented caveats to runtime characteristics are understood and bugs and minor API adjustments are not too costly.

41.6.2 Deprecation

In addition to being labelled `Early Access`, features and components can also be labelled `Deprecated`. Deprecation follows a deprecation cycle laid out in the table below. The date of deprecation is documented in [Daml Ecosystem Overview](#).

Deprecated features can be relied upon during the deprecation cycle to the same degree as their non-deprecated counterparts, but building on deprecated features may hinder an upgrade to new Daml versions following the deprecation cycle.

41.6.3 Comparison of Statuses

The table below gives a concise overview of the labels used for Daml features and components.

Table 1: Feature Maturities

	Stable	Beta	Alpha	Labs
Functional-ity				
Functional Completeness	Functionally complete	Considered functionally complete, but subject to change according to usability testing	MVP-level functionality covering at least a few core use-cases	Functionality covering one specific use-case it was made for
Non-functional Re-quire-ments				
Performance	Unless stated otherwise, the feature can be used without concern about system performance.	Current performance impacts and expected performance for the stable release are documented.	Using the feature may have significant undocumented impact on overall system performance.	Using the feature may have significant undocumented impact on overall system performance.
Compatibility	Compatibility is covered by Portability, Compatibility, and Support Durations .	Compatibility is covered by Portability, Compatibility, and Support Durations .	The feature may only work against specific Daml integrations, or specific API versions, including Early Access ones.	The feature may only work against specific Daml integrations, or specific API versions, including Early Access ones.
Stability & Error Recovery	The feature is long-term stable and supports recovery fit for a production system.	No known reproducible crashes which can't be recovered from. There is still an expectation that new issues may be discovered.	The feature may not be stable and lack error recovery.	The feature may not be stable and lack error recovery.
Re-leases and Support				
Distribution and Re-leases	Distributed as part of regular releases .	Distributed as part of regular releases .	Distributed as part of regular releases .	Releases and distribution may be separate.
Support	Covered by standard commercial support terms. Hotfixes for critical bugs and security issues are available.	Not covered by standard commercial support terms. Receives bug- and security fixes with regular releases.	Not covered by standard commercial support terms. Receives bug- and security fixes with regular releases.	Not covered by standard commercial support terms. Only receives fixes with low priority.
Deprecation	May be removed with any new major version 12 months after the date of deprecation.	May be removed with any new minor version 1 month after the date of deprecation.	May be removed without warning.	May be removed without warning.
Covered	Yes, part of the	No, but breaking	No, and changes	No, and changes

Chapter 42

Releases and Versioning

42.1 Versioning

All Daml components follow [Semantic Versioning](#). In short, this means that there is a well defined public API , changes or breakages to which are indicated by the version number.

Stable releases have versions MAJOR.MINOR.PATCH. Segments of the version are incremented according to the following rules:

1. MAJOR version when there are incompatible API changes,
2. MINOR version when functionality is added in a backwards compatible manner, and
3. PATCH version when there are only backwards compatible bug fixes.

Daml's public API is laid out in the [Daml Ecosystem Overview](#).

42.2 Cadence

Regular, weekly snapshot releases are made every Wednesday, with additional snapshots produced as needed. These releases contain Daml Components, both from the [daml repository](#) as well as some others.

The decision to perform a Minor version release is based on the content or scope of the payload of that release. The intent is to release a Minor version once a quarter but this may change based on the customer demand for new, key features.

No more than one major version is released every six months, barring exceptional circumstances.

Individual Daml drivers follow their own release cadence, using already released Integration Components as a dependency.

42.3 Support Duration

Major versions will be supported for a minimum of one year after a subsequent Major version is release. Within a major version, security and bug fixes are applied to the latest Minor version as well as the second to last Minor version release, the latter being limited to 6 months after its release or 3 months after the release of the latest Minor version, whichever is longer.

42.4 Release Notes

Release notes for each release are published on the [Release Notes section of the Daml Driven blog](#).

42.5 Process

Weekly snapshot and Minor releases follow a common process. The process is documented [in the Daml repository](#). Only the schedule for Minor releases is covered below.

Selecting a Release Candidate

This is done by the Daml core engineering teams.

The Minor releases are scope-based. Furthermore, Daml development is fully HEAD-based so both the repository and every snapshot are intended to be in a fully releasable state at every point. The release process therefore starts with selecting a release candidate . Typically the Snapshot from the preceding Wednesday is selected as the release candidate.

Release Notes and Candidate Review

After selecting the release candidate, Release Notes are written and reviewed with a particular view towards unintended changes and violations of [Semantic Versioning](#).

Release Candidate Refinement

If issues surface in the initial review, the issues are resolved and different Snapshot is selected as the release candidate.

Release Candidate Announcement

Barring delays due to issues during initial review, the release candidate is announced publicly with accompanying Release Notes.

Communications, Testing and Feedback

In the days following the announcement, the release is presented and discussed with both commercial and community users. It is also put through its paces by integrating it in [Daml Hub](#) and several ledger integrations.

Release Candidate Refinement II

Depending on feedback and test results, new release candidates may be issued iteratively. Depending on the severity of changes from release candidate to release candidate, the testing period is extended more or less.

Release

Assuming the release is not postponed due to extended test periods or newly discovered issues in the release candidate, the release is declared stable and given a regular version number.

Chapter 43

Glossary of concepts

43.1 Key Concepts

43.1.1 Daml

Daml is a platform for building and running sophisticated, multi-party applications. At its core, it contains a smart contract [language](#) and [tooling](#) that defines the schema, semantics, and execution of transactions between parties. Daml includes [Canton](#), a privacy-enabled distributed ledger that is enhanced when deployed with complementary blockchains.

43.1.2 Daml Language

The Daml language is a purpose-built language for rapid development of composable multi-party applications. It is a modern, ergonomically designed functional language that carefully avoids many of the pitfalls that hinder multi-party application development in other languages.

43.1.3 Daml Ledger

A Daml ledger is a distributed ledger system running [Daml smart contracts](#) according to the [Daml ledger model](#) and exposes the Daml Ledger APIs. All current implementations of Daml ledgers consist of a Daml driver that utilizes an underlying Synchronization Technology to either implement the Daml ledger directly or to run the Canton protocol.

43.1.3.1 Canton Ledger

A Canton ledger is a privacy-enabled Daml ledger implemented using the Canton application, nodes, and protocol.

43.1.4 Canton Protocol

The Canton protocol is the technology that synchronizes [participant nodes](#) across any Daml-enabled blockchain or database. The Canton protocol not only makes Daml applications portable between different underlying [synchronization technologies](#), but also allows applications to transact with each other across them.

43.1.5 Synchronization Technology

The synchronization technology is the database or blockchain that Daml uses for synchronization, messaging, and topology. Daml runs on a range of synchronization technologies, from centralized databases to fully distributed deployments, and users can employ the technology that best suits their technical and operational needs.

43.1.6 Daml Drivers

Daml drivers enable a [ledger](#) to be implemented on top of different [synchronization technologies](#); a database or distributed ledger technology.

43.2 Daml Language Concepts

43.2.1 Contract

Contracts are items on a [ledger](#). They are created from blueprints called [templates](#), and include:

- data (parameters)
- roles ([signatory](#), [observer](#))
- [choices](#) (and [controllers](#))

Contracts are immutable: once they are created on the ledger, the information in the contract cannot be changed. The only thing that can happen to them is that they can be [archived](#).

43.2.1.1 Active Contract, Archived Contract

When a [contract](#) is created on a [ledger](#), it becomes **active**. But that doesn't mean it will remain active forever: it can be **archived**. This can happen:

- if the [signatories](#) of the contract decide to archive it
- if a [consuming choice](#) is exercised on the contract

Once the contract is archived, it is no longer valid, and [choices](#) on the contract can no longer be exercised.

43.2.2 Template

A **template** is a blueprint for creating a [contract](#). This is the Daml code you write.

For full documentation on what can be in a template, see [Reference: Templates](#).

43.2.3 Choice

A **choice** is something that a [party](#) can [exercise](#) on a [contract](#). You write code in the choice body that specifies what happens when the choice is exercised: for example, it could create a new contract.

Choices give one a way to transform the data in a contract: while the contract itself is immutable, you can write a choice that [archives](#) the contract and creates a new version of it with updated data.

A choice can only be exercised by its [controller](#). Within the choice body, you have the [authorization](#) of all of the contract's [signatories](#).

For full documentation on choices, see [Reference: Choices](#).

43.2.3.1 Consuming Choice

A **consuming choice** means that, when the choice is exercised, the [contract](#) it is on will be [archived](#). The alternative is a [nonconsuming choice](#).

Consuming choices can be [preconsuming](#) or [postconsuming](#).

Preconsuming Choice

A [choice](#) marked **preconsuming** will be [archived](#) at the start of that [exercise](#).

Postconsuming Choice

A [choice](#) marked **postconsuming** will not be [archived](#) until the end of the [exercise](#) choice body.

43.2.3.2 Nonconsuming Choice

A **nonconsuming choice** does NOT [archive](#) the [contract](#) it is on when [exercised](#). This means the choice can be exercised more than once on the same [contract](#).

43.2.3.3 Disjunction Choice, Flexible Controllers

A **disjunction choice** has more than one [controller](#).

If a contract uses **flexible controllers**, this means you don't specify the controller of the [choice](#) at [creation](#) time of the [contract](#), but at [exercise](#) time.

43.2.4 Party

A **party** represents a person or legal entity. Parties can [create contracts](#) and [exercise choices](#).

Signatories, observers, controllers, and maintainers all must be parties, represented by the **Party** data type in contract data.

Parties are hosted on participant nodes and a participant node can host more than one party. A party can be hosted on several participant nodes simultaneously.

43.2.4.1 Signatory

A **signatory** is a [party](#) on a [contract](#). The signatories MUST consent to the [creation](#) of the contract by [authorizing](#) it: if they don't, contract creation will fail. Once the contract is created, signatories can see the contracts and all exercises of that contract.

For documentation on signatories, see [Reference: Templates](#).

43.2.4.2 Observer

An **observer** is a [party](#) on a [contract](#). Being an observer allows them to see that instance and all the information about it. They do NOT have to [consent to](#) the creation.

For documentation on observers, see [Reference: Templates](#).

43.2.4.3 Controller

A **controller** is a [party](#) that is able to [exercise](#) a particular [choice](#) on a particular [contract](#).

Controllers must be at least an [observer](#), otherwise they can't see the contract to exercise it on. But they don't have to be a [signatory](#). this enables the [propose-accept pattern](#).

43.2.4.4 Choice Observer

A **choice observer** is a [party](#) on a [choice](#). Choice observers are guaranteed to see the choice being exercised and all its consequences with it.

43.2.4.5 Stakeholder

Stakeholder is not a term used within the Daml language, but the concept refers to the [signatories](#) and [observers](#) collectively. That is, it means all of the [parties](#) that are interested in a [contract](#).

43.2.4.6 Maintainer

The **maintainer** is a [party](#) that is part of a [contract key](#). They must always be a [signatory](#) on the [contract](#) that they maintain the key for.

It's not possible for keys to be globally unique, because there is no party that will necessarily know about every contract. However, by including a party as part of the key, this ensures that the maintainer *will* know about all of the contracts, and so can guarantee the uniqueness of the keys that they know about.

For documentation on contract keys, see [Reference: Contract Keys](#).

43.2.5 Authorization, Signing

The Daml runtime checks that every submitted transaction is **well-authorized**, according to the [authorization rules of the ledger model](#), which guarantee the integrity of the underlying ledger.

A Daml update is the composition of update actions created with one of the items in the table below. A Daml update is well-authorized when **all** its contained update actions are well-authorized. Each operation has an associated set of parties that need to authorize it:

Table 1: Updates and required authorization

Update action	Type	Authorization
create	<code>(Template c) => c -> Update (ContractId c)</code>	All signatories of the created contract
exercise	<code>ContractId c -> e -> Update r</code>	All controllers of the choice
fetch	<code>ContractId c -> e -> Update r</code>	One of the union of signatories and observers of the fetched contract
fetch-ByKey	<code>k -> Update (ContractId c, c)</code>	Same as fetch
lookup-ByKey	<code>k -> Update (Optional (ContractId c))</code>	All key maintainers

At runtime, the Daml execution engine computes the required authorizing parties from this mapping. It also computes which parties have given authorization to the update in question. A party gives authorization to an update in one of two ways:

- It is the signatory of the contract that contains the update action.

- It is an element of the controllers executing the choice containing the update action.

Only if all required parties have given their authorization to an update action, the update action is well-authorized and therefore executed. A missing authorization leads to the abortion of the update action and the failure of the containing transaction.

It is noteworthy, that authorizing parties are always determined only from the local context of a choice in question, that is, its controllers and the contract's signatories. Authorization is never inherited from earlier execution contexts.

43.2.6 Standard Library

The **Daml standard library** is a set of *Daml* functions, classes and more that make developing with Daml easier.

For documentation, see [The Standard Library](#).

43.2.7 Agreement

An **agreement** is part of a [contract](#). It is the text that explains what the contract represents.

It can be used to clarify the legal intent of a contract, but this text isn't evaluated programmatically.

See [Reference: Templates](#).

43.2.8 Create

A **create** is an update that creates a [contract](#) on the [ledger](#).

Contract creation requires [authorization](#) from all its [signatories](#), or the create will fail. For how to get authorization, see the [propose-accept](#) and [multi-party agreement](#) patterns.

A [party submits](#) a create [command](#).

See [Reference: Updates](#).

43.2.9 Exercise

An **exercise** is an action that exercises a [choice](#) on a [contract](#) on the [ledger](#). If the choice is [consuming](#), the exercise will [archive](#) the contract; if it is [nonconsuming](#), the contract will stay active.

Exercising a choice requires [authorization](#) from all of the [controllers](#) of the choice.

A [party submits](#) an exercise [command](#).

See [Reference: Updates](#).

43.2.10 Daml Script

Daml Script provides a way of testing Daml code during development. You can run Daml Script inside *Daml Studio*, or write them to be executed on [Sandbox](#) when it starts up.

They're useful for:

- expressing clearly the intended workflow of your [contracts](#)
- ensuring that parties can exclusively create contracts, observe contracts, and exercise choices that they are meant to
- acting as regression tests to confirm that everything keeps working correctly

In Daml Studio, Daml Script runs in an emulated ledger. You specify a linear sequence of actions that various parties take, and these are evaluated in order, according to the same consistency, authorization, and privacy rules as they would be on a Daml ledger. Daml Studio shows you the resulting transaction graph, and (if a Daml Script fails) what caused it to fail.

See [Test Templates Using Daml Script](#).

43.2.11 Contract Key

A **contract key** allows you to uniquely identify a [contract](#) of a particular [template](#), similar to a primary key in a database table.

A contract key requires a [maintainer](#): a simple key would be something like a tuple of text and maintainer, like `(accountId, bank)`.

See [Reference: Contract Keys](#).

43.2.12 DAR File, DALF File

A Daml Archive file, known as a `.dar` file is the result of compiling Daml code using the [Assistant](#) which can be interpreted using a Daml interpreter.

You upload `.dar` files to a [ledger](#) in order to be able to create contracts from the templates in that file.

A `.dar` contains multiple `.dalf` files. A `.dalf` file is the output of a compiled Daml package or library. Its underlying format is [Daml-LF](#).

43.3 Developer Tools

43.3.1 Assistant

Daml Assistant is a command-line tool for many tasks related to Daml. Using it, you can create Daml projects, compile Daml projects into [.dar files](#), launch other developer tools, and download new SDK versions.

See [Daml Assistant](#).

43.3.2 Studio

Daml Studio is a plugin for Visual Studio Code, and is the IDE for writing Daml code.

See [Write: Daml Studio](#).

43.3.3 Sandbox

Sandbox is a lightweight ledger implementation. In its normal mode, you can use it for testing.

You can also run the Sandbox connected to a PostgreSQL back end, which gives you persistence and a more production-like experience.

See [Test: Daml Sandbox](#).

43.3.4 Navigator (Deprecated)

Navigator is a tool for exploring what's on the ledger. You can use it to see what contracts can be seen by different parties, and [submit commands](#) on behalf of those parties.

43.3.4.1 Navigator GUI

This is the version of Navigator that runs as a web app.

See [Visualize: Daml Navigator \(Deprecated\)](#).

43.4 Building Applications

43.4.1 Application, Ledger Client, Integration

Application, **ledger client**, and **integration** are all terms for an application that sits on top of the [ledger](#). These usually [read from the ledger](#), [send commands](#) to the ledger, or both.

There's a lot of information available about application development, starting with the [Daml Application Architecture](#) page.

43.4.2 Ledger API

The **Ledger API** is an API that's exposed by any [ledger](#) on a participant node. Users access and manipulate the ledger state through the Ledger API. An alternative name for the Ledger API is the **gRPC Ledger API** if disambiguation from other technologies is needed. See [Build Integration with the Ledger API](#) page. It includes the following [services](#).

43.4.2.1 Command Submission Service

Use the **command submission service** to [submit commands](#) - either create commands or exercise commands - to the [ledger](#). See [Command Submission Service](#).

43.4.2.2 Command Completion Service

Use the **command completion service** to find out whether or not [commands you have submitted](#) have completed, and what their status was. See [Command Completion Service](#).

43.4.2.3 Command Service

Use the **command service** when you want to [submit a command](#) and wait for it to be executed. See [Command Service](#).

43.4.2.4 Transaction Service

Use the **transaction service** to listen to changes in the [ledger](#), reported as a stream of transactions. See [Transaction Service](#).

43.4.2.5 Active Contract Service

Use the **active contract service** to obtain a party-specific view of all [contracts](#) currently [active](#) on the [ledger](#). See [Active Contracts Service](#).

43.4.2.6 Package Service

Use the **package service** to obtain information about Daml packages available on the [ledger](#). See [Package Service](#).

43.4.2.7 Ledger Identity Service

Use the **ledger identity service** to get the identity string of the [ledger](#) that your application is connected to. See [Ledger Identity Service \(DEPRECATED\)](#).

43.4.2.8 Ledger Configuration Service

Use the **ledger configuration service** to subscribe to changes in [ledger](#) configuration. See [Ledger Configuration Service](#).

43.4.3 Ledger API Libraries

The following libraries wrap the [ledger API](#) for more native experience applications development.

43.4.3.1 Java Bindings

An idiomatic Java library for writing [ledger applications](#). See [Java Bindings](#).

43.4.3.2 Python Bindings

A Python library (formerly known as DAZL) for writing [ledger applications](#). See [Python Bindings](#).

43.4.4 Reading From the Ledger

[Applications](#) get information about the [ledger](#) by **reading** from it. You can't query the ledger, but you can subscribe to the transaction stream to get the events, or the more sophisticated active contract service.

43.4.5 Submitting Commands, Writing To the Ledger

[Applications](#) make changes to the [ledger](#) by **submitting commands**. You can't change it directly: an application submits a command of *transactions*. The command gets evaluated by the runtime, and will only be accepted if it's valid.

For example, a command might get rejected because the transactions aren't [well-authorized](#); because the contract isn't [active](#) (perhaps someone else archived it); or for other reasons.

This is echoed in [Daml script](#), where you can mock an application by having parties submit transactions/updates to the ledger. You can use `submit` or `submitMustFail` to express what should succeed and what shouldn't.

43.4.5.1 Commands

A **command** is an instruction to add a transaction to the [ledger](#).

43.4.6 Participant Node

The participant node is a server that provides users with consistent programmatic access to a ledger through the [Ledger API](#). The participant nodes handle transaction signing and validation, such that users don't have to deal with cryptographic primitives but can trust the participant node that the data they are observing has been properly verified to be correct.

43.4.7 Sub-transaction Privacy

Sub-transaction privacy is where participants in a transaction only [learn about the subset of the transaction](#) they are directly involved in, but not about any other part of the transaction. This applies to both the content of the transaction as well as other involved participants.

43.4.8 Daml-LF

When you compile Daml source code into a [.dar file](#), the underlying format is **Daml-LF**. Daml-LF is similar to Daml, but is stripped down to a core set of features. The relationship between the surface Daml syntax and Daml-LF is loosely similar to that between Java and JVM bytecode.

As a user, you don't need to interact with Daml-LF directly. But internally, it's used for:

- executing Daml code on the Sandbox or on another platform
- sending and receiving values via the Ledger API (using a protocol such as gRPC)
- generating code in other languages for interacting with Daml models (often called `codegen`)

43.4.9 Composability

Composability is the ability of a participant to extend an existing system with new Daml applications or new topologies unilaterally without requiring cooperation from anyone except the directly involved participants who wish to be part of the new application functionality.

43.4.10 Trust Domain

A trust domain encompasses a part of the system (in particular, a Daml ledger) operated by a single real-world entity. This subsystem may consist of one or more physical nodes. A single physical machine is always assumed to be controlled by exactly one real-world entity.

43.5 Canton Concepts

43.5.1 Synchronization Domain

The sync domain provides total ordered, guaranteed delivery multi-cast to the participants. This means that participant nodes communicate with each other by sending end-to-end encrypted messages through the sync domain.

The [sequencer service](#) of the sync domain orders these messages without knowing about the content and ensures that every participant receives the messages in the same order.

The other services of the sync domain are the [mediator](#) and the *sync domain identity manager*.

43.5.2 Private Contract Store

Every participant node manages its own private contract store (PCS) which contains only contracts the participant is privy to. There is no global state or global contract store.

43.5.3 Virtual Global Ledger

While every participant has their own private contract store (PCS), the [Canton protocol](#) guarantees that the contracts which are stored in the PCS are well-authorized and that any change to the store is justified, authorized, and valid. The result is that every participant only possesses a small part of the *virtual global ledger*. All the local stores together make up that *virtual global ledger* and they are thus synchronized. The Canton protocol guarantees that the virtual ledger provides integrity, privacy, transparency, and auditability. The ledger is logically global, even though physically, it runs on segregated and isolated sync domains that are not aware of each other.

43.5.4 Mediator

The mediator is a service provided by the *sync domain* and used by the [Canton protocol](#). The mediator acts as commit coordinator, collecting individual transaction verdicts issued by validating participants and aggregating them into a single result. The mediator does not learn about the content of the transaction, they only learn about the involved participants.

43.5.5 Sequencer

The sequencer is a service provided by the *sync domain*, used by the [Canton protocol](#). The sequencer forwards encrypted addressed messages from participants and ensures that every member receives the messages in the same order. Think about registered and sealed mail delivered according to the postal timestamp.

43.5.6 Synchronization Domain Identity Manager

The sync domain identity manager is a service provided by the *sync domain*, used by the [Canton protocol](#). Participants join a new sync domain by registering with the sync domain identity manager. The sync domain identity manager establishes a consistent identity state among all participants. The sync domain identity manager only forwards identity updates. It can not invent them.

43.5.7 Consensus

The Canton protocol does not use PBFT or any similar consensus algorithm. There is no proof of work or proof of stake involved. Instead, Canton uses a variant of a stakeholder-based two-phase commit protocol. As such, only stakeholders of a transaction are involved in it and need to process it, providing efficiency, privacy, and horizontal scalability. Canton-based ledgers are resilient to malicious participants as long as there is at least a single honest participant. A sync domain integration itself might be using the consensus mechanism of the underlying platform, but participant nodes will not be involved in that process.

Chapter 45

Daml Language References

45.1 Daml Language Cheat Sheet

Click to open the

45.2 Language Reference

This section contains a reference to writing templates for Daml contracts. It includes:

45.2.1 Overview: Template Structure

This page covers what a template looks like: what parts of a template there are, and where they go.

For the structure of a Daml file outside a template, see [Reference: Daml File Structure](#).

45.2.1.1 Template Outline Structure

Here's the structure of a Daml template:

```
template NameOfTemplate
  with
    exampleParty : Party
    exampleParty2 : Party
    exampleParty3 : Party
    exampleParameter : Text
    -- more parameters here
  where
    signatory exampleParty
    observer exampleParty2
    agreement
      -- some text
      ""
    ensure
      -- boolean condition
      True
  key (exampleParty, exampleParameter) : (Party, Text)
```

(continues on next page)

(continued from previous page)

```
maintainer (exampleFunction key)
-- a choice goes here; see next section
```

template name `template` keyword

parameters `with` followed by the names of parameters and their types

template body `where` keyword

Can include:

template-local definitions (deprecated) `let` keyword

Lets you make definitions that have access to the contract arguments and are available in the rest of the template definition.

signatories `signatory` keyword

Required. The parties (see the [Party](#) type) who must consent to the creation of this contract. You won't be able to create this contract until all of these parties have authorized it.

observers `observer` keyword

Optional. Parties that aren't signatories but who you still want to be able to see this contract.

an agreement (deprecated) `agreement` keyword

Optional. Text that describes the agreement that this contract represents.

a precondition `ensure` keyword

Only create the contract if the conditions after `ensure` evaluate to true.

a contract key `key` keyword

Optional. Lets you specify a combination of a party and other data that uniquely identifies a contract of this template. See [Reference: Contract Keys](#).

maintainers `maintainer` keyword

Required if you have specified a key. Keys are only unique to a maintainer. See [Reference: Contract Keys](#).

choices `choice NameOfChoice : ReturnType controller nameOfParty do`

Defines choices that can be exercised. See [Choice structure](#) for what can go in a choice.

45.2.1.2 Choice Structure

Here is the structure of a choice inside a template:

```
choice NameOfChoice
: () -- replace () with the actual return type
with
  party : Party -- parameters here
controller party
do
  return () -- replace this line with the choice body
```

consumption annotation Optionally one of `preconsuming`, `postconsuming`, `nonconsuming`, which changes the behavior of the choice with respect to privacy and if and when the contract is archived. See [contract consumption in choices](#) for more details.

a name Must begin with a capital letter. Must be unique - choices in different templates can't have the same name.

a return type after a `:`, the return type of the choice

choice arguments `with` keyword

If you include a `Party` as a choice argument, you can make that `Party` the controller of the choice. This means that the controller can be specified when the choice is exercised, rather

than when the contract is created. For the exercise to work, the party needs to be able to see the contract, i.e. it must be an observer or a signatory.

a controller (or controllers) `controller` keyword

Who can exercise the choice.

choice observers `observer` keyword

Optional. Additional parties that are guaranteed to be informed of an exercise of the choice.

To specify choice observers, you must start your choice with the `choice` keyword.

The optional `observer` keyword must precede the mandatory `controller` keyword.

a choice body After `do` keyword

What happens when someone exercises the choice. A choice body can contain update statements: see [Choice body structure](#) below.

45.2.1.3 Choice Body Structure

A choice body contains `Update` expressions, wrapped in a `do` block.

The update expressions are:

create Create a new contract of this template.

```
create NameOfContract with contractArgument1 = value1; contractArgument2 = value2; ...
```

exercise Exercise a choice on a particular contract.

```
exercise idOfContract NameOfChoiceOnContract with choiceArgument1 = value1; choiceArgument2 = value 2; ...
```

fetch Fetch a contract using its ID. Often used with `assert` to check conditions on the contract's content.

```
fetchContract <- fetch IdOfContract
```

fetchByKey Like `fetch`, but uses a [contract key](#) rather than an ID.

```
fetchContract <- fetchByKey @ContractType contractKey
```

lookupByKey Confirm that a contract with the given [contract key](#) exists.

```
fetchContractId <- lookupByKey @ContractType contractKey
```

abort Stop execution of the choice, fail the update.

```
if False then abort
```

assert Fail the update unless the condition is true. Usually used to limit the arguments that can be supplied to a contract choice.

```
assert (amount > 0)
```

getTime Gets the ledger time. Usually used to restrict when a choice can be exercised.

```
currentTime <- getTime
```

return Explicitly return a value. By default, a choice returns the result of its last update expression. This means you only need to use `return` if you want to return something else.

```
return ContractID ExampleTemplate
```

The choice body can also contain:

let keyword Used to assign values or functions.

assign a value to the result of an update statement For example: `contractFetched <- fetch someContractId`

45.2.2 Reference: Templates

This page gives reference information on templates:

For the structure of a template, see [Overview: Template Structure](#).

45.2.2.1 Template Name

```
template NameOfTemplate
```

This is the name of the template. It's preceded by `template` keyword. Must begin with a capital letter.

This is the highest level of nesting.

The name is used when [creating](#) a contract of this template (usually, from within a choice).

45.2.2.2 Template Parameters

```
with
  exampleParty : Party
  exampleParty2 : Party
  exampleParty3 : Party
  exampleParam : Text
  -- more parameters here
```

`with` keyword. The parameters are in the form of a [record type](#).

Passed in when [creating](#) a contract from this template. These are then in scope inside the template body.

A template parameter can't have the same name as any [choice arguments](#) inside the template. For all parties involved in the contract (whether they're a signatory, observer, or controller) you must pass them in as parameters to the contract, whether individually or as a list (`[Party]`).

45.2.2.3 Implicit Record

Whenever a template is defined, a record is implicitly defined with the same name and fields as that template. This record structure is used in Daml code to represent the data of a contract based on that template.

Note that in the general case, the existence of a local binding `b` of type `T`, where `T` is a template (and thus also a record), does not necessarily imply the existence of a contract with the same data as `b` on the ledger. You can only assume the existence of such a contract if `b` is the result of a fetch from the ledger within the same transaction.

You can create a new instance of a record of type `T` without any interaction with the ledger; in fact, this is how you construct a create command.

45.2.2.4 `this` and `self`

Within the body of a template we implicitly define a local binding `this` to represent the data of the current contract. For a template `T`, this binding is of type `T`, i.e. the implicit record defined by the template.

Within choices, you can additionally use the binding `self` to refer to the contract ID of the current contract (the one on which the choice is being executed). For a contract of template `T`, the `self` binding is of type `ContractId T`.

45.2.2.5 Template-local Definitions (Deprecated)

```
where
  let
    allParties = [exampleParty, exampleParty2, exampleParty3]
```

`let` keyword. Starts a block and is followed by any number of definitions, just like any other `let` block.

Template parameters as well as `this` are in scope, but `self` is not.

Definitions from the `let` block can be used anywhere else in the template's `where` block.

Warning: Since Daml 2.8.0, template-local definitions are deprecated and their presence will result in the following warning:

```
Template-local binding syntax ("template-let") is deprecated,
it will be removed in a future version of Daml.
Instead, use plain top level definitions, taking parameters
for the contract fields or body ("this") if necessary.
```

The reason for this deprecation is that some uses of the `this` keyword in template-local definitions would create implicit circular dependencies, causing an infinite loop upon evaluation.

Migration

Users are strongly encouraged to adapt their code to avoid this feature. This involves replacing each template-local definition with a regular top-level definition. If the old definition made use of contract fields or the contract body (`this`), the new definition should take them as parameters. Correspondingly, the use sites of these definitions should supply the appropriate values as arguments.

For example, consider the template `Person` below. It defines and uses a template-local binding `fullName`, which now triggers the deprecation warning.

```
template Person
  with
    owner : Party
    first : Text
    last : Text
  where
    signatory owner
    let fullName = last <> ", " <> first
    nonconsuming choice GetDescription : ()
```

(continues on next page)

(continued from previous page)

```

controller owner
do
  let desc = "An account owned by " <> fullName <> "."
  debug desc

```

To ensure this code keeps working after the feature is removed, `fullName` should be defined as a top-level function, and its use site now passes `this` explicitly.

```

fullName : Person -> Text
fullName Person {first, last} = last <> ", " <> first
-- takes 'Person' as an explicit parameter and unpacks required fields

template Person
with
  owner : Party
  first : Text
  last : Text
where
  signatory owner
  nonconsuming choice GetDescriptionV3 : ()
  controller owner
  do
    -- let bindings in choice bodies are unaffected
    let desc = "An account owned by " <> fullName this <> "."
    -- 'this' is passed explicitly
    debug desc

```

Turning off the warning

This warning is controlled by the warning flag `template-let`, which means that it can be toggled independently of other warnings. This is especially useful for gradually migrating code that used this syntax.

To turn off the warning within a Daml file, add the following line at the top of the file:

```
{-# OPTIONS_GHC -Wno-template-let #-}
```

To turn it off for an entire Daml project, add the following entry to the `build-options` field of the project's `daml.yaml` file

```

build-options:
- --ghc-option=-Wno-template-let

```

Within a project where the warning has been turned off via the `daml.yaml` file, it can be turned back on for individual Daml files by adding the following line at the top of each file:

```
{-# OPTIONS_GHC -Wtemplate-let #-}
```

45.2.2.6 Signatory Parties

```
signatory exampleParty
```

`signatory` keyword. After `where`. Followed by at least one `Party`.

Signatories are the parties (see the `Party` type) who must consent to the creation of this contract. They are the parties who would be put into an *obligable position* when this contract is created.

Daml won't let you put someone into an obligable position without their consent. So if the contract will cause obligations for a party, they *must* be a signatory. **If they haven't authorized it, you won't be able to create the contract.** In this situation, you may see errors like:

```
NameOfTemplate requires authorizers Party1,Party2,Party, but only
Party1 were given.
```

When a signatory consents to the contract creation, this means they also authorize the consequences of [choices](#) that can be exercised on this contract.

The contract is visible to all signatories (as well as the other stakeholders of the contract). That is, the compiler automatically adds signatories as observers.

Each template **must** have at least one signatory. A signatory declaration consists of the `signatory` keyword followed by a comma-separated list of one or more expressions, each expression denoting a `Party` or collection thereof.

45.2.2.7 Observers

```
observer exampleParty2
```

`observer` keyword. After `where`. Followed by at least one `Party`.

Observers are additional stakeholders, so the contract is visible to these parties (see the `Party` type).

Optional. You can have many, either as a comma-separated list or reusing the keyword. You could pass in a list (of type `[Party]`).

Use when a party needs visibility on a contract, or be informed of contract events, but is not a [signatory](#) or [controller](#).

If you start your choice with `choice` rather than `controller` (see [Choices](#) below), you must make sure to add any potential controller as an observer. Otherwise, they will not be able to exercise the choice, because they won't be able to see the contract.

45.2.2.8 Choices

```
choice NameOfChoice
: () -- replace () with the actual return type
with
  exampleParameter : Text -- parameters here
controller exampleParty
do
  return () -- replace this line with the choice body
```

A right that the contract gives the controlling party. Can be exercised.

This is essentially where all the logic of the template goes.

By default, choices are *consuming*: that is, exercising the choice archives the contract, so no further choices can be exercised on it. You can make a choice non-consuming using the `non-consuming` keyword.

See [Reference: Choices](#) for full reference information.

45.2.2.9 Serializable Types

Every parameter to a template, choice argument, and choice result must have a *serializable* type. This does not merely mean convertible to bytes ; it has a specific meaning in Daml. The serializability rule serves three purposes:

1. Offer a stable means to store ledger values permanently.
2. Provide a sensible encoding of them over [Build Integration with the Ledger API](#).
3. Provide sensible types that directly match their Daml counterparts in languages like Java for language codegen.

For example, certain kinds of type parameters Daml offers are compatible with (1) and (2), but have no proper counterpart in (3), so they are disallowed. Similarly, function types have sensible Java counterparts, satisfying (3), but no reliable way to store or share them via the API, thus failing (1) and (2).

The following types are *not serializable*, and thus may not be used in templates.

Function types.

Record types with any non-serializable field.

Variant types with any non-serializable value case.

Variant and enum types with no constructors.

References to a parameterized data type with any non-serializable type argument. This applies whether or not the data type definition uses the type parameter.

Defined data types with any type parameter of kind `Nat`, or any kind other than `*`. This means higher-kinded types, and types that take a parameter just to pass to `Numeric`, are not serializable.

45.2.2.10 Agreements (Deprecated)

```
agreement
  -- text representing the contract
  ""
```

`agreement` keyword, followed by text.

Represents what the contract means in text. They're usually the boundary between on-ledger and off-ledger rights and obligations.

Usually, they look like `agreement tx`, where `tx` is of type `Text`.

You can use the built-in operator `show` to convert party names to a string, and concatenate with `<>`.

Warning: Since Daml 2.9.0, agreement declarations are deprecated, and their presence will result in the following warning:

```
Found 'agreement' declaration in template definition.
This feature is deprecated, it will be removed in a future version of Daml.
```

Migration

Users are encouraged to remove any agreement declarations from their code, to ensure it will continue working once this feature is fully removed from the language.

Turning off the warning

This warning is controlled by the warning flag `template-agreement`, which means that it can be toggled independently of other warnings. This is especially useful for gradually migrating code that used this feature.

To turn off the warning within a Daml file, add the following line at the top of the file:

```
{-# OPTIONS_GHC -Wno-template-agreement #-}
```

To turn it off for an entire Daml project, add the following entry to the `build-options` field of the project's `daml.yaml` file:

```
build-options:
- --ghc-option=-Wno-template-agreement
```

Within a project where the warning has been turned off via the `daml.yaml` file, it can be turned back on for individual Daml files by adding the following line at the top of each file:

```
{-# OPTIONS_GHC -Wtemplate-agreement #-}
```

45.2.2.11 Preconditions

```
ensure
  True -- a boolean condition goes here
```

`ensure` keyword, followed by a boolean condition.

Used on contract creation. `ensure` limits the values on parameters that can be passed to the contract: the contract can only be created if the boolean condition is true.

45.2.2.12 Contract Keys and Maintainers

```
key (exampleParty, exampleParam) : (Party, Text)
maintainer (exampleFunction key)
```

`key` and `maintainer` keywords.

This feature lets you specify a `key` that you can use to uniquely identify this contract as an instance of this template.

If you specify a `key`, you must also specify a `maintainer`. This is a `Party` that will ensure the uniqueness of all the keys it is aware of.

Because of this, the `key` must include the `maintainer` `Party` or parties (for example, as part of a tuple or record), and the `maintainer` must be a signatory.

For a full explanation, see [Reference: Contract Keys](#).

45.2.2.13 Interface Instances

```
interface instance MyInterface for NameOfTemplate where
  view = MyInterfaceViewType "NameOfTemplate" 100
  method1 = field1
  method2 = field2
  method3 False _ _ = 0
  method3 True x y
    | x > 0 = x + y
    | otherwise = y
```

Used to make a template an instance of an existing interface.

The clause must start with the keywords `interface instance`, followed by the name of the interface, then the keyword `for` and the name of the template (which must match the enclosing declaration), and finally the keyword `where`, which introduces a block where **all** the methods of the interface must be implemented.

See [Reference: Interfaces](#) for full reference information on interfaces, or section [Interface Instances](#) for interface instances specifically.

45.2.3 Reference: Choices

This page gives reference information on choices. For information on the high-level structure of a choice, see [Overview: Template Structure](#).

45.2.3.1 Choice Name

```
choice ExampleChoice
  : () -- replace () with the actual return type
```

`choice` keyword

The name of the choice. Must begin with a capital letter.

Must be unique in the module. Different templates defined in the same module cannot share a choice name.

45.2.3.2 Controllers

```
controller exampleParty
```

`controller` keyword

The controller is a comma-separated list of values, where each value is either a party or a collection of parties.

The conjunction of **all** the parties are required to authorize when this choice is exercised.

Warning: You **must** make sure that the controller parties are observers (or signatories) of the contract, otherwise they cannot see the contract (and therefore cannot exercise the choice).

45.2.3.3 Choice Observers

Choice observers can be attached to a choice using the `observer` keyword. The choice observers are a list of parties who are not stakeholders but who see all the consequences of the action.

```
choice NameOfChoiceWithObserver
: () -- replace () with the actual return type
with
  party : Party -- parameters here
observer party -- optional specification of choice observers
controller exampleParty
do
  return () -- replace this line with the choice body
```

Contract Consumption

If no qualifier is present, choices are *consuming*: the contract is archived before the evaluation of the choice body and both the controllers and all contract stakeholders see all consequences of the action.

45.2.3.4 Preconsuming Choices

```
preconsuming choice ExamplePreconsumingChoice
: () -- replace () with the actual return type
```

`preconsuming` keyword. Optional.

Makes a choice pre-consuming: the contract is archived before the body of the exercise is executed.

The create arguments of the contract can still be used in the body of the exercise, but cannot be fetched by its contract id.

The archival behavior is analogous to the *consuming* default behavior.

Only the controllers and signatories of the contract see all consequences of the action. Other stakeholders merely see an archive action.

Can be thought as a non-consuming choice that implicitly archives the contract before anything else happens

45.2.3.5 Postconsuming Choices

```
postconsuming choice ExamplePostconsumingChoice
: () -- replace () with the actual return type
```

`postconsuming` keyword. Optional.

Makes a choice post-consuming: the contract is archived after the body of the exercise is executed.

The create arguments of the contract can still be used in the body of the exercise as well as the contract id for fetching it.

Only the controllers and signatories of the contract see all consequences of the action. Other stakeholders merely see an archive action.

Can be thought as a non-consuming choice that implicitly archives the contract after the choice has been exercised

45.2.3.6 Non-consuming Choices

```
nonconsuming choice ExampleNonconsumingChoice
  : () -- replace () with the actual return type
```

`nonconsuming` keyword. Optional.

Makes a choice non-consuming: that is, exercising the choice does not archive the contract. Only the controllers and signatories of the contract see all consequences of the action. Useful in the many situations when you want to be able to exercise a choice more than once.

Return Type

Return type is written immediately after choice name.

All choices have a return type. A contract returning nothing should be marked as returning a unit, ie ().

If a contract is/contracts are created in the choice body, usually you would return the contract ID(s) (which have the type `ContractId <name of template>`). This is returned when the choice is exercised, and can be used in a variety of ways.

45.2.3.7 Choice Arguments

```
with
  exampleParameter : Text
```

`with` keyword.

Choice arguments are similar in structure to [Template Parameters](#): a *record type*.

A choice argument can't have the same name as any *parameter to the template* the choice is in. Optional - only if you need extra information passed in to exercise the choice.

45.2.3.8 Choice Body

Introduced with `do`

The logic in this section is what is executed when the choice gets exercised.

The choice body contains `Update` expressions. For detail on this, see [Reference: Updates](#).

By default, the last expression in the choice is returned. You can return multiple updates in tuple form or in a custom data type. To return something that isn't of type `Update`, use the `return` keyword.

45.2.4 Reference: Updates

This page gives reference information on Updates. For the structure around them, see [Overview: Template Structure](#).

45.2.4.1 Background

An `Update` is ledger update. There are many different kinds of these, and they're listed below. They are what can go in a [choice body](#).

45.2.4.2 Binding Variables

```
boundVariable <- UpdateExpression1
```

One of the things you can do in a choice body is bind (assign) an Update expression to a variable. This works for any of the Updates below.

45.2.4.3 do

```
do
  updateExpression1
  updateExpression2
```

`do` can be used to group Update expressions. You can only have one update expression in a choice, so any choice beyond the very simple will use a `do` block.

Anything you can put into a choice body, you can put into a `do` block.

By default, `do` returns whatever is returned by the **last expression in the block**.

So if you want to return something else, you'll need to use `return` explicitly - see [return](#) for an example.

45.2.4.4 archive

```
archive ContractId
```

`archive` function.

Archives a contract already created and residing on the ledger. The contract is fetched by its unique contract identifier `ContractId <name of template>` and then exercises the `Archive` choice on it.

Returns unit.

Requires authorization from the contract controllers/signatories. Without the required authorization, the transaction fails. For more detail on authorization, see [Signatory Parties](#).

All templates implicitly have an `Archive` choice that cannot be removed, which is equivalent to:

```
choice Archive : ()
  controller (signatory this)
  do return ()
```

45.2.4.5 create

```
create NameOfTemplate with exampleParameters
```

create function.

Creates a contract on the ledger. When a contract is committed to the ledger, it is given a unique contract identifier of type `ContractId` <name of template>.

Creating the contract returns that `ContractId`.

Use `with` to specify the template parameters.

Requires authorization from the signatories of the contract being created. This is given by being signatories of the contract from which the other contract is created, being the controller, or explicitly creating the contract itself.

If the required authorization is not given, the transaction fails. For more detail on authorization, see [Signatory Parties](#).

45.2.4.6 exercise

```
exercise IdOfContract NameOfChoiceOnContract with choiceArgument1 = value1
```

exercise function.

Exercises the specified choice on the specified contract.

Use `with` to specify the choice parameters.

Requires authorization from the controller(s) of the choice. If the authorization is not given, the transaction fails.

45.2.4.7 exerciseByKey

```
exerciseByKey @ContractType contractKey NameOfChoiceOnContract with  
↳choiceArgument1 = value1
```

exerciseByKey function.

Like `exercise`, but the contract is specified by [contract key](#), instead of contract ID.

For details see [Reference: Contract Keys: exerciseByKey](#)

45.2.4.8 fetch

```
fetchedContract <- fetch IdOfContract
```

fetch function.

Fetches the contract with that ID. Usually used with a bound variable, as in the example above. Often used to check the details of a contract before exercising a choice on that contract. Also used when referring to some reference data.

`fetch cid` fails if `cid` is not the contract id of an active contract, and thus causes the entire transaction to abort.

The submitting party must be an observer or signatory on the contract, otherwise `fetch` fails, and similarly causes the entire transaction to abort.

45.2.4.9 fetchByKey

```
fetchContract <- fetchByKey @ContractType contractKey
```

fetchByKey function.

Like `fetch`, but fetches the contract with that [contract key](#), instead of the contract ID.

For details see [Reference: Contract Keys: fetchByKey](#).

45.2.4.10 visibleByKey

```
isVisible <- visibleByKey @ContractType contractKey
```

visibleByKey function.

Use this to check whether a contract with the given [contract key](#) exists.

For details see [Reference: Contract Keys: visibleByKey](#)

45.2.4.11 lookupByKey

```
fetchContractId <- lookupByKey @ContractType contractKey
```

lookupByKey function.

Use this to confirm that a contract with the given [contract key](#) exists.

For details see [Reference: Contract Keys: lookupByKey](#)

45.2.4.12 abort

```
abort errorMessage
```

abort function.

Fails the transaction - nothing in it will be committed to the ledger.

`errorMessage` is of type `Text`. Use the error message to provide more context to an external system (e.g., it gets displayed in Daml Studio script results).

You could use `assert False` as an alternative.

45.2.4.13 assert

```
assert (condition == True)
```

assert keyword.

Fails the transaction if the condition is false. So the choice can only be exercised if the boolean expression evaluates to `True`.

Often used to restrict the arguments that can be supplied to a contract choice.

Here's an example of using `assert` to prevent a choice being exercised if the `Party` passed as a parameter is on a blacklist:

```
choice Transfer : ContractId RestrictedPayout
  with newReceiver : Party
  controller receiver
  do
    assert (newReceiver /= blacklisted)
    create RestrictedPayout with receiver = newReceiver; giver; blacklisted; □
← qty
```

45.2.4.14 getTime

```
currentTime <- getTime
```

getTime keyword.

Gets the ledger time. (You will usually want to immediately bind it to a variable in order to be able to access the value.)

Used to restrict when a choice can be made. For example, with an `assert` that the time is later than a certain time.

Here's an example of a choice that uses a check on the current time:

```
choice Complete : ()
  controller party
  do
    -- bind the ledger effective time to the tchoose variable using getTime
    tchoose <- getTime
    -- assert that tchoose is no earlier than the begin time
    assert (begin <= tchoose && tchoose < addRelTime begin period)
```

45.2.4.15 return

```
return ()
```

return keyword.

Used to return a value from `do` block that is not of type `Update`.

Here's an example where two contracts are created in a choice and both their ids are returned as a tuple:

```
do
  firstContract <- create SomeContractTemplate with arg1; arg2
  secondContract <- create SomeContractTemplate with arg1; arg2
  return (firstContract, secondContract)
```

45.2.4.16 `let`

See the documentation on [Let](#).

Let looks similar to binding variables, but it's very different! This code example shows how:

```
do
  -- defines a function, createContract, taking a single argument that when
  -- called _will_ create the new contract using argument for issuer and owner
  let createContract x = create NameOfContract with issuer = x; owner = x

  createContract party1
  createContract party2
```

45.2.4.17 `this`

`this` lets you refer to the current contract from within the choice body. This refers to the contract, not the contract ID.

It's useful, for example, if you want to pass the current contract to a helper function outside the template.

45.2.5 Reference: Data Types

This page gives reference information on Daml's data types.

45.2.5.1 Built-in Types

Table of built-in primitive types

Type	For	Example	Notes
Int	integers	1, 1000000, 1_000_000	Int values are signed 64-bit integers which represent numbers between -9,223,372,036,854,775,808 and 9,223,372,036,854,775,807 inclusive. Arithmetic operations raise an error on overflows and division by 0. To make long numbers more readable you can optionally add underscores.
Decimal	short for Numeric 10	1.0	Decimal values are rational numbers with precision 38 and scale 10.
Numeric n	fixed point decimal numbers	1.0	Numeric n values are rational numbers with 38 total digits. The scale parameter n controls the number of digits after the decimal point, so for example, Numeric 10 values have 28 digits before the decimal point and 10 digits after it, and Numeric 20 values have 18 digits before the decimal point and 20 digits after it. The value of n must be between 0 and 37 inclusive.
BigNumeric	large fixed point decimal numbers	1.0	BigNumeric values are rational numbers with up to 2 ¹⁶ decimal digits. They can have up to 2 ¹⁵ digits before the decimal point, and up to 2 ¹⁵ digits after the decimal point.
Text	strings	"hello"	Text values are strings of characters enclosed by double quotes.
Bool	boolean values	True, False	
Party	unicode string representing a party	alice <- getParty "Alice"	Every party in a Daml system has a unique identifier of type Party. To create a value of type Party, use binding on the result of calling getParty. The party text can only contain alphanumeric characters, -, _ and spaces.
Date	models dates	date 2007 Apr 5	Permissible dates range from 0001-01-01 to 9999-12-31 (using a year-month-day format). To create a value of type Date, use the function date (to get this function, import DA.Date).
Time	models absolute time (UTC)	time (date 2007 Apr 5) 14 30 05	Time values have microsecond precision with allowed range from 0001-01-01 to 9999-12-31 (using a year-month-day format). To create a value of type Time, use a Date and the function time (to get this function, import DA.Time).
RelTime	models differences between time values	seconds 1, seconds (-2)	RelTime values have microsecond precision with allowed range from -9,223,372,036,854,775,808ms to 9,223,372,036,854,775,807ms There are no literals for RelTime. Instead they are created using one of days, hours, minutes, seconds, milliseconds and microseconds (to get these functions, import DA.Time).
1838			Chapter 45: Daml Language References

Escaping Characters

Text literals support backslash escapes to include their delimiter (`\"`) and a backslash itself (`\\`).

Time

Definition of time on the ledger is a property of the execution environment. Daml assumes there is a shared understanding of what time is among the stakeholders of contracts.

45.2.5.2 Lists

`[a]` is the built-in data type for a list of elements of type `a`. The empty list is denoted by `[]` and `[1, 3, 2]` is an example of a list of type `[Int]`.

You can also construct lists using `[]` (the empty list) and `::` (which is an operator that appends an element to the front of a list). For example:

```
twoEquivalentListConstructions =
  script do
    assert ( [1, 2, 3] == 1 :: 2 :: 3 :: [] )
```

Sum a List

To sum a list, use a *fold* (because there are no loops in Daml). See [Fold](#) for details.

45.2.5.3 Records and Record Types

You declare a new record type using the `data` and `with` keyword:

```
data MyRecord = MyRecord
  with
    label1 : type1
    label2 : type2
    ...
    labelN : typeN
  deriving (Eq, Show)
```

where:

`label1, label2, ..., labelN` are *labels*, which must be unique in the record type
`type1, type2, ..., typeN` are the types of the fields

There's an alternative way to write record types:

```
data MyRecord = MyRecord { label1 : type1; label2 : type2; ...; labelN : typeN }
  deriving (Eq, Show)
```

The format using `with` and the format using `{ }` are exactly the same syntactically. The main difference is that when you use `with`, you can use newlines and proper indentation to avoid the delimiting semicolons.

The deriving (Eq, Show) ensures the data type can be compared (using ==) and displayed (using show). The line starting deriving is required for data types used in fields of a template.

In general, add the deriving unless the data type contains function types (e.g. Int -> Int), which cannot be compared or shown.

For example:

```
-- This is a record type with two fields, called first and second,
-- both of type `Int`
data MyRecord = MyRecord with first : Int; second : Int
  deriving (Eq, Show)

-- An example value of this type is:
newRecord = MyRecord with first = 1; second = 2

-- You can also write:
newRecord = MyRecord 1 2
```

Data Constructors

You can use data keyword to define a new data type, for example data Floor a = Floor a for some type a.

The first Floor in the expression is the type constructor. The second Floor is a data constructor that can be used to specify values of the Floor Int type: for example, Floor 0, Floor 1.

In Daml, data constructors may take at most one argument.

An example of a data constructor with zero arguments is data Empty = Empty {}. The only value of the Empty type is Empty.

Note: In data Confusing = Int, the Int is a data constructor with no arguments. It has nothing to do with the built-in Int type.

Access Record Fields

To access the fields of a record type, use dot notation. For example:

```
-- Access the value of the field `first`
val.first

-- Access the value of the field `second`
val.second
```

Update Record Fields

You can also use the `with` keyword to create a new record on the basis of an existing replacing select fields.

For example:

```
myRecord = MyRecord with first = 1; second = 2
myRecord2 = myRecord with second = 5
```

produces the new record value `MyRecord` with `first = 1; second = 5`.

If you have a variable with the same name as the label, Daml lets you use this without assigning it to make things look nicer:

```
-- if you have a variable called `second` equal to 5
second = 5

-- you could construct the same value as before with
myRecord2 = myRecord with second = second

-- or with
myRecord3 = MyRecord with first = 1; second = second

-- but Daml has a nicer way of putting this:
myRecord4 = MyRecord with first = 1; second

-- or even
myRecord5 = r with second
```

Note: The `with` keyword binds more strongly than function application. So for a function, say `return`, either write `return IntegerCoordinate with first = 1; second = 5` or `return (IntegerCoordinate {first = 1; second = 5})`, where the latter expression is enclosed in parentheses.

Parameterized Data Types

Daml supports parameterized data types.

For example, to express a more general type for 2D coordinates:

```
-- Here, a and b are type parameters.
-- The Coordinate after the data keyword is a type constructor.
data Coordinate a b = Coordinate with first : a; second : b
```

An example of a type that can be constructed with `Coordinate` is `Coordinate Int Int`.

45.2.5.4 Type Synonyms

To declare a synonym for a type, use the `type` keyword.

For example:

```
type IntegerTuple = (Int, Int)
```

This makes `IntegerTuple` and `(Int, Int)` synonyms: they have the same type and can be used interchangeably.

You can use the `type` keyword for any type, including [Built-in Types](#).

Function Types

A function's type includes its parameter and result types. A function `foo` with two parameters has type `ParamType1 -> ParamType2 -> ReturnType`.

Note that this can be treated as any other type. You could for instance give it a synonym using `type FooType = ParamType1 -> ParamType2 -> ReturnType`.

45.2.5.5 Algebraic Data Types

An algebraic data type is a composite type: a type formed by a combination of other types. The enumeration data type is an example. This section introduces more powerful algebraic data types.

Product Types

The following data constructor is not valid in Daml: `data AlternativeCoordinate a b = AlternativeCoordinate a b`. This is because data constructors can only have one argument.

To get around this, wrap the values in a [record](#): `data Coordinate a b = Coordinate {first: a; second: b}`.

These kinds of types are called *product* types.

A way of thinking about this is that the `Coordinate Int Int` type has a first and second dimension (that is, a 2D product space). By adding an extra type to the record, you get a third dimension, and so on.

Sum Types

Sum types capture the notion of being of one kind or another.

An example is the built-in data type `Bool`. This is defined by `data Bool = True | False deriving (Eq, Show)`, where `True` and `False` are data constructors with zero arguments. This means that a `Bool` value is either `True` or `False` and cannot be instantiated with any other value.

Please note that all types which you intend to use as template or choice arguments need to derive at least from `(Eq, Show)`.

A very useful sum type is `data Optional a = None | Some a deriving (Eq, Show)`. It is part of the [Daml standard library](#).

`Optional` captures the concept of a box, which can be empty or contain a value of type `a`.

`Optional` is a sum type constructor taking a type `a` as parameter. It produces the sum type defined by the data constructors `None` and `Some`.

The `Some` data constructor takes one argument, and it expects a value of type `a` as a parameter.

Pattern Matching

You can match a value to a specific pattern using the `case` keyword.

The pattern is expressed with data constructors. For example, the `Optional Int` sum type:

```
import Daml.Script
import DA.Assert

optionalIntegerToText (x : Optional Int) : Text =
  case x of
    None -> "Box is empty"
    Some val -> "The content of the box is " <> show val

optionalIntegerToTextTest =
  script do
```

In the `optionalIntegerToText` function, the `case` construct first tries to match the `x` argument against the `None` data constructor, and in case of a match, the `"Box is empty"` text is returned. In case of no match, a match is attempted for `x` against the next pattern in the list, i.e., with the `Some` data constructor. In case of a match, the content of the value attached to the `Some` label is bound to the `val` variable, which is then used in the corresponding output text string.

Note that all patterns in the `case` construct need to be *complete*, i.e., for each `x` there must be at least one pattern that matches. The patterns are tested from top to bottom, and the expression for the first pattern that matches will be executed. Note that `_` can be used as a catch-all pattern.

You could also case distinguish a `Bool` variable using the `True` and `False` data constructors and achieve the same behavior as an if-then-else expression.

As an example, the following is an expression for a `Text`:

```
tmp =
  let
    l = [1, 2, 3]
  in case l of
```

Notice the use of nested pattern matching above.

Note: An underscore was used in place of a variable name. The reason for this is that [Daml Studio](#) produces a warning for all variables that are not being used. This is useful in detecting unused variables. You can suppress the warning by naming the variable with an initial underscore.

45.2.6 Reference: Built-in Functions

This page gives reference information on built-in functions for working with a variety of common concepts.

45.2.6.1 Work with Time

Daml has these built-in functions for working with time:

`datetime`: creates a `Time` given year, month, day, hours, minutes, and seconds as argument.
`subTime`: subtracts one time from another. Returns the `RelTime` difference between `time1` and `time2`.
`addRelTime`: add times. Takes a `Time` and `RelTime` and adds the `RelTime` to the `Time`.
`days, hours, minutes, seconds`: constructs a `RelTime` of the specified length.
`pass`: (in [Daml Script tests](#) only) use `pass : RelTime -> Script Time` to advance the ledger time by the argument amount. Returns the new time.

45.2.6.2 Work with Numbers

Daml has these built-in functions for working with numbers:

`round`: rounds a `Decimal` number to `Int`.
`round d` is the nearest `Int` to `d`. Tie-breaks are resolved by rounding away from zero, for example:

```
round 2.5 == 3      round (-2.5) == -3
round 3.4 == 3      round (-3.7) == -4
```

`truncate`: converts a `Decimal` number to `Int`, truncating the value towards zero, for example:

```
truncate 2.2 == 2      truncate (-2.2) == -2
truncate 4.9 == 4      v (-4.9) == -4
```

`intToDecimal`: converts an `Int` to `Decimal`.

The set of numbers expressed by `Decimal` is not closed under division as the result may require more than 10 decimal places to represent. For example, `1.0 / 3.0 == 0.3333...` is a rational number, but not a `Decimal`.

45.2.6.3 Work with Text

Daml has these built-in functions for working with text:

`<>` operator: concatenates two `Text` values.
`show` converts a value of the primitive types (`Bool`, `Int`, `Decimal`, `Party`, `Time`, `RelTime`) to a `Text`.

To escape text in Daml strings, use `\`:

Character	How to escape it
\	\\
"	\"
'	\'
Newline	\n
Tab	\t
Carriage return	\r
Unicode (using ! as an example)	Decimal code: \33 Octal code: \o41 Hexadecimal code: \x21

45.2.6.4 Work with Lists

Daml has these built-in functions for working with lists:

`foldl` and `foldr`: see [Fold](#) below.

Fold

A *fold* takes:

- a binary operator
- a first *accumulator* value
- a list of values

The elements of the list are processed one-by-one (from the left in a `foldl`, or from the right in a `foldr`).

Note: We'd usually recommend using `foldl`, as `foldr` is usually slower. This is because it needs to traverse the whole list before starting to discharge its elements.

Processing goes like this:

1. The binary operator is applied to the first accumulator value and the first element in the list. This produces a second accumulator value.
2. The binary operator is applied to the *second* accumulator value and the second element in the list. This produces a third accumulator value.
3. This continues until there are no more elements in the list. Then, the last accumulator value is returned.

As an example, to sum up a list of integers in Daml:

```
sumList =
  script do
    assert (foldl (+) 0 [1, 2, 3] == 6)
```

45.2.7 Reference: Expressions

This page gives reference information for Daml expressions that are not [updates](#).

45.2.7.1 Definitions

Use assignment to bind values or functions at the top level of a Daml file or in a contract template body.

Values

For example:

```
pi = 3.1415926535
```

The fact that `pi` has type `Decimal` is inferred from the value. To explicitly annotate the type, mention it after a colon following the variable name:

```
pi : Decimal = 3.1415926535
```

Functions

You can define functions. Here's an example: a function for computing the surface area of a tube:

```
tubeSurfaceArea : Decimal -> Decimal -> Decimal
tubeSurfaceArea r h =
  2.0 * pi * r * h
```

Here you see:

- the name of the function

- the function's type signature `Decimal -> Decimal -> Decimal`

- This means it takes two `Decimals` and returns another `Decimal`.

- the definition = `2.0 * pi * r * h` (which uses the previously defined `pi`)

45.2.7.2 Arithmetic Operators

Operator	Works for
+	Int, Decimal, RelTime
-	Int, Decimal, RelTime
*	Int, Decimal
/ (integer division)	Int
% (integer remainder operation)	Int
^ (integer exponentiation)	Int

The result of the modulo operation has the same sign as the dividend:

`7 / 3` and `(-7) / (-3)` evaluate to `2`

`(-7) / 3` and `7 / (-3)` evaluate to `-2`
`7 % 3` and `7 % (-3)` evaluate to `1`
`(-7) % 3` and `(-7) % (-3)` evaluate to `-1`

To write infix expressions in prefix form, wrap the operators in parentheses. For example, `(+) 1 2` is another way of writing `1 + 2`.

45.2.7.3 Comparison Operators

Operator	Works for
<code><</code> , <code><=</code> , <code>></code> , <code>>=</code>	Bool, Text, Int, Decimal, Party, Time
<code>==</code> , <code>/=</code>	Bool, Text, Int, Decimal, Party, Time, and identifiers of contracts stemming from the same contract template

45.2.7.4 Logical Operators

The logical operators in Daml are:

`not` for negation, e.g., `not True == False`
`&&` for conjunction, where `a && b == and a b`
`||` for disjunction, where `a || b == or a b`

for Bool variables `a` and `b`.

45.2.7.5 If-then-else

You can use conditional *if-then-else* expressions, for example:

```
if owner == scroogeMcDuck then "sell" else "buy"
```

45.2.7.6 Let

To bind values or functions to be in scope beneath the expression, use the block keyword `let`:

```
doubled =
  -- let binds values or functions to be in scope beneath the expression
  let
    double (x : Int) = 2 * x
    up = 5
  in double up
```

You can also use `let` inside `do` blocks:

```
blah = script
  do
    let
      x = 1
      y = 2
      -- x and y are in scope for all subsequent expressions of the do block,
      -- so can be used in expression1 and expression2.
```

(continues on next page)

(continued from previous page)

```
expression1
expression2
```

45.2.8 Reference: Functions

This page gives reference information on functions in Daml.

Daml is a functional language. It lets you apply functions partially and also have functions that take other functions as arguments. This page discusses these *higher-order functions*.

45.2.8.1 Defining Functions

In [Reference: Expressions](#), the `tubeSurfaceArea` function was defined as:

```
tubeSurfaceArea : Decimal -> Decimal -> Decimal
tubeSurfaceArea r h =
  2.0 * pi * r * h
```

You can define this function equivalently using lambdas, involving `\`, a sequence of parameters, and an arrow `->` as:

```
tubeSurfaceArea : BinaryDecimalFunction =
  \ (r : Decimal) (h : Decimal) -> 2.0 * pi * r * h
```

45.2.8.2 Partial Application

The type of the `tubeSurfaceArea` function described previously, is `Decimal -> Decimal -> Decimal`. An equivalent, but more instructive, way to read its type is: `Decimal -> (Decimal -> Decimal)`: saying that `tubeSurfaceArea` is a function that takes *one* argument and returns another function.

So `tubeSurfaceArea` expects one argument of type `Decimal` and returns a function of type `Decimal -> Decimal`. In other words, this function returns another function. *Only the last application of an argument yields a non-function.*

This is called *currying*: currying is the process of converting a function of multiple arguments to a function that takes just a single argument and returns another function. In Daml, all functions are curried.

This doesn't affect things that much. If you use functions in the classical way (by applying them to all parameters) then there is no difference.

If you only apply a few arguments to the function, this is called *partial application*. The result is a function with partially defined arguments. For example:

```
multiplyThreeNumbers : Int -> Int -> Int -> Int
multiplyThreeNumbers xx yy zz =
  xx * yy * zz

multiplyTwoNumbersWith7 = multiplyThreeNumbers 7
```

(continues on next page)

(continued from previous page)

```
multiplyWith21 = multiplyTwoNumbersWith7 3

multiplyWith18 = multiplyThreeNumbers 3 6
```

You could also define equivalent lambda functions:

```
multiplyWith18_v2 : Int -> Int
multiplyWith18_v2 xx =
  multiplyThreeNumbers 3 6 xx
```

45.2.8.3 Functions are Values

The function type can be explicitly added to the `tubeSurfaceArea` function (when it is written with the lambda notation):

```
-- Type synonym for Decimal -> Decimal -> Decimal
type BinaryDecimalFunction = Decimal -> Decimal -> Decimal

pi : Decimal = 3.1415926535

tubeSurfaceArea : BinaryDecimalFunction =
  \ (r : Decimal) (h : Decimal) -> 2.0 * pi * r * h
```

Note that `tubeSurfaceArea : BinaryDecimalFunction = ...` follows the same pattern as when binding values, e.g., `pi : Decimal = 3.1415926535`.

Functions have types, just like values. Which means they can be used just like normal variables. In fact, in Daml, functions are values.

This means a function can take another function as an argument. For example, define a function `applyFilter`: `(Int -> Int -> Bool) -> Int -> Int -> Bool` which applies the first argument, a higher-order function, to the second and the third arguments to yield the result.

```
applyFilter (filter : Int -> Int -> Bool)
  (x : Int)
  (y : Int) = filter x y

compute = script do
  applyFilter (<) 3 2 === False
  applyFilter (/=) 3 2 === True

  round (2.5 : Decimal) === 3
  round (3.5 : Decimal) === 4

  explode "me" === ["m", "e"]

  applyFilter (\a b -> a /= b) 3 2 === True
```

The [Fold](#) section looks into two useful built-in functions, `foldl` and `foldr`, that also take a function as an argument.

Note: Daml does not allow functions as parameters of contract templates and contract choices. However, a follow up of a choice can use built-in functions, defined at the top level or in the contract

template body.

45.2.8.4 Generic Functions

A function is *parametrically polymorphic* if it behaves uniformly for all types, in at least one of its type parameters. For example, you can define function composition as follows:

```
compose (f : b -> c) (g : a -> b) (x : a) : c = f (g x)
```

where `a`, `b`, and `c` are any data types. Both `compose ((+) 4) ((* 2) 3) == 10` and `compose not ((&&) True) False` evaluate to `True`. Note that `((+) 4)` has type `Int -> Int`, whereas `not` has type `Bool -> Bool`.

You can find many other generic functions including this one in the [Daml standard library](#).

Note: Daml currently does not support generic functions for a specific set of types, such as `Int` and `Decimal` numbers. For example, `sum (x: a) (y: a) = x + y` is undefined when `a` equals the type `Party`. *Bounded polymorphism* might be added to Daml in a later version.

45.2.9 Reference: Daml File Structure

This page gives reference information on the structure of Daml files outside of [templates](#).

45.2.9.1 File Structure

This file's module name (`module NameOfThisFile where`).

Part of a hierarchical module system to facilitate code reuse. Must be the same as the Daml file name, without the file extension.

For a file with path `./Scenarios/Demo.daml`, use `module Scenarios.Demo where`.

45.2.9.2 Imports

You can import other modules (`import OtherModuleName`), including qualified imports (`import qualified AndYetOtherModuleName, import qualified AndYetOtherModule as Signifier`). Can't have circular import references.

To import the `Prelude` module of `./Prelude.daml`, use `import Prelude`.

To import a module of `./Scenarios/Demo.daml`, use `import Scenarios.Demo`.

If you leave out `qualified`, and a module alias is specified, top-level declarations of the imported module are imported into the module's namespace as well as the namespace specified by the given alias.

45.2.9.3 Libraries

A Daml library is a collection of related Daml modules.

Define a Daml library using a `LibraryModules.daml` file: a normal Daml file that imports the root modules of the library. The library consists of the `LibraryModules.daml` file and all its dependencies, found by recursively following the imports of each module.

Errors are reported in Daml Studio on a per-library basis. This means that breaking changes on shared Daml modules are displayed even when the files are not explicitly open.

45.2.9.4 Comments

Use `--` for a single line comment. Use `{ - and - }` for a comment extending over multiple lines.

45.2.9.5 Contract Identifiers

When an instance of a template (that is, a contract) is added to the ledger, it's assigned a unique identifier, of type `ContractId <name of template>`.

The runtime representation of these identifiers depends on the execution environment: a contract identifier from the Sandbox may look different to ones on other Daml Ledgers.

You can use `==` and `/=` on contract identifiers of the same type.

45.2.10 Reference: Daml Packages

This page gives reference information on Daml package dependencies.

45.2.10.1 Building Daml Archives

When a Daml project is compiled, the compiler produces a *Daml archive*. These are platform-independent packages of compiled Daml code that can be uploaded to a Daml ledger or imported in other Daml projects.

Daml archives have a `.dar` file ending. By default, when you run `daml build`, it will generate the `.dar` file in the `.daml/dist` folder in the project root folder. For example, running `daml build` in project `foo` with project version `0.0.1` will result in a Daml archive `.daml/dist/foo-0.0.1.dar`.

You can specify a different path for the Daml archive by using the `-o` flag:

```
daml build -o foo.dar
```

The rest of this page will focus on how to import a Daml package **in** other Daml  projects.

45.2.10.2 Inspecting DARs

To inspect a DAR and get information about the packages inside it, you can use the `daml damlc inspect-dar` command. This is often useful to find the package id of the project you just built.

You can run `daml damlc inspect-dar /path/to/your.dar` to get a human-readable listing of the files inside it and a list of packages and their package ids. Here is a (shortened) example output:

```
$ daml damlc inspect-dar .daml/dist/create-daml-app-0.1.0.dar
DAR archive contains the following files:

create-daml-app-0.1.0-

Note that `name` and `version` will be `null` for packages in Daml-LF < 1.8.

45.2.10.3 Import Daml Packages

There are two ways to import a Daml package in a project: via `dependencies`, and via `data-dependencies`. They each have certain advantages and disadvantages. To summarize:

`dependencies` allow you to import a Daml archive as a library. The definitions in the dependency will all be made available to the importing project. However, the dependency must be compiled with the same SDK version, so this method is only suitable for breaking up large projects into smaller projects that depend on each other, or to reuse existing libraries.

`data-dependencies` allow you to import a Daml archive (`.dar`) or a Daml-LF package (`.dalf`), including packages that have already been deployed to a ledger. These packages can be compiled with any previous SDK version. On the other hand, not all definitions can be carried over perfectly, since the Daml interface needs to be reconstructed from the binary.

The following sections will cover these two approaches in more depth.

Import a Daml package via Dependencies

A Daml project can declare a Daml archive as a dependency in the `dependencies` field of `daml.yaml`. This lets you import modules and reuse definitions from another Daml project. The main limitation of this method is that the dependency must be built for the same SDK version as the importing project.

Let's go through an example. Suppose you have an existing Daml project `foo`, located at `/home/user/foo`, and you want to use it as a dependency in a project `bar`, located at `/home/user/bar`.

To do so, you first need to generate the Daml archive of `foo`. Go into `/home/user/foo` and run `daml build -o foo.dar`. This will create the Daml archive, `/home/user/foo/foo.dar`.

Next, we will update the project config for `bar` to use the generated Daml archive as a dependency. Go into `/home/user/bar` and change the `dependencies` field in `daml.yaml` to point to the created Daml archive:

```
dependencies:
- daml-prim
- daml-stdlib
- ../foo/foo.dar
```

The import path can also be absolute, for example, by changing the last line to:

```
- /home/user/foo/foo.dar
```

When you run `daml build` in the `bar` project, the compiler will make the definitions in `foo.dar` available for importing. For example, if `foo` exports the module `Foo`, you can import it in the usual way:

```
import Foo
```

By default, all modules of `foo` are made available when importing `foo` as a dependency. To limit which modules of `foo` get exported, you may add an `exposed-modules` field in the `daml.yaml` file for `foo`:

```
exposed-modules:
```

```
- Foo
```

Import a Daml Archive via `data-dependencies`

You can import a Daml archive (.dar) or Daml-LF package (.dalf) using `data-dependencies`. Unlike `dependencies`, this can be used when the SDK versions do not match.

For example, you can import `foo.dar` as follows:

```
dependencies:
```

```
- daml-prim  
- daml-stdlib
```

```
data-dependencies:
```

```
- ../foo/foo.dar
```

When importing packages this way, the Daml compiler will try to reconstruct the original Daml interface from the compiled binaries. However, to allow `data-dependencies` to work across SDK versions, the compiler has to abstract over some details which are not compatible across SDK versions. This means that there are some Daml features that cannot be recovered when using `data-dependencies`. In particular:

1. Export lists cannot be recovered, so imports via `data-dependencies` can access definitions that were originally hidden. This means it is up to the importing module to respect the data abstraction of the original module. Note that this is the same for all code that runs on the ledger, since the ledger does not provide special support for data abstraction.
2. If you have a dependency that limits the modules that can be accessed via `exposed-modules`, you can get an error if you also have a `data-dependency` that references something from the hidden modules (even if it is only reexported). Since `exposed-modules` are not available on the ledger in general, we recommend to not make use of them and instead rely on naming conventions (e.g., suffix module names with `.Internal`) to make it clear which modules are part of the public API.
3. Prior to Daml-LF version 1.8, typeclasses could not be reconstructed. This means if you have a package that is compiled with an older version of Daml-LF, typeclasses and typeclass instances will not be carried over via `data-dependencies`, and you won't be able to call functions that rely on typeclass instances. This includes the template functions, such as `create`, `signatory`, and `exercise`, as these rely on typeclass instances.
4. Starting from Daml-LF version 1.8, when possible, typeclass instances will be reconstructed by re-using the typeclass definitions from dependencies, such as the typeclasses exported in `daml-stdlib`. However, if the typeclass signature has changed, you will get an instance for a reconstructed typeclass instead, which will not interoperate with code from dependencies.

Because of their flexibility, `data-dependencies` are a tool that is recommended for performing Daml model upgrades. See the [upgrade documentation](#) for more details.

Transitive dependency management

The Daml compiler identifies each DAR dependency in the project by its `packageId` and fully qualified name (Daml project package name and version number).

If you have a Daml project which contains multiple common transitive DAR dependencies, those common transitive dependencies must either:

- Have identical contents if they have the same name and version specified in their Daml project's `daml.yaml` file, or
- Have a different value for the `version` entry in their respective `daml.yaml` files.

Otherwise, the Daml project cannot be built into a deployable DAR due to package identification conflicts.

For example:

- Daml project X (top-level) has dependencies `DarA` and `DarB`.
- `DarA` and `DarB` both contain DAR dependency `DarC`

When compiling Daml project X, you must ensure that the `DarC` dependency referenced by both `DarA` and `DarB` either has identical Daml contents or has a different version number if the contents differ. The version number is defined in the `daml.yaml` file of the Daml project producing `DarC`, under the `version` key.

Reference Daml Packages Already On the Ledger

Daml packages that have been uploaded to a ledger can be imported as data dependencies, given you have the necessary permissions to download these packages. To import such a package, add the package name and version separated by a colon to the data-dependencies stanza as follows:

```
ledger:
  host: localhost
  port: 6865
dependencies:
- daml-prim
- daml-stdlib
data-dependencies:
- foo:1.0.0
```

If your ledger runs at the default host and port (`localhost:6865`), the ledger stanza can be omitted. This will fetch and install the package `foo-1.0.0`. A `daml.lock` file is created at the root of your project directory, pinning the resolved packages to their exact package ID:

```
dependencies:
- pkgId: 51255efad65a1751bcee749d962a135a65d12b87eb81ac961142196d8bbca535
  name: foo
  version: 1.0.0
```

The `daml.lock` file needs to be checked into version control of your project. This assures that package name/version tuples specified in your data dependencies are always resolved to the same package ID. To recreate or update your `daml.lock` file, delete it and run `daml build` again.

45.2.10.4 Handling Module Name Collisions

Sometimes you will have multiple packages with the same module name. In that case, a simple import will fail, since the compiler doesn't know which version of the module to load. Fortunately, there are a few tools you can use to approach this problem.

The first is to use package qualified imports. Supposing you have packages with different names, `foo` and `bar`, which both expose a module `X`, you can select which one you want with a package qualified import.

To get `X` from `foo`:

```
import "foo" X
```

To get `X` from `bar`:

```
import "bar" X
```

To get both, you need to rename the module as you perform the import:

```
import "foo" X as FooX
import "bar" X as BarX
```

Sometimes, package qualified imports will not help, because you are importing two packages with the same name. For example, if you're loading different versions of the same package. To handle this case, you need the `--package` build option.

Suppose you are importing packages `foo-1.0.0` and `foo-2.0.0`. Notice they have the same name `foo` but different versions. To get modules that are exposed in both packages, you will need to provide module aliases. You can do this by passing the `--package` build option. Open `daml.yaml` and add the following build-options:

```
build-options:
- '--package'
- 'foo-1.0.0 with (X as Foo1.X) '
- '--package'
- 'foo-2.0.0 with (X as Foo2.X) '
```

This will alias the `X` in `foo-1.0.0` as `Foo1.X`, and alias the `X` in `foo-2.0.0` as `Foo2.X`. Now you will be able to import both `X` by using the new names:

```
import qualified Foo1.X
import qualified Foo2.X
```

It is also possible to add a prefix to all modules in a package using the `module-prefixes` field in your `daml.yaml`. This is particularly useful for upgrades where you can map all modules of version `v` of your package under `V$v`. For the example above you can use the following:

```
module-prefixes:
  foo-1.0.0: Foo1
  foo-2.0.0: Foo2
```

That will allow you to import module `X` from package `foo-1.0.0` as `Foo1.X` and `X` from package `foo-2.0.0` as `Foo2`.

You can also use more complex module prefixes, e.g., `foo-1.0.0: Foo1.Bar` which will make module `X` available under `Foo1.Bar.X`.

45.2.11 Reference: Contract Keys

Contract keys are an optional addition to templates. They let you specify a way of uniquely identifying contracts, using the parameters to the template - similar to a primary key for a database.

Contract keys do not change and can be used to refer to a contract even when the contract id changes.

Here's an example of setting up a contract key for a bank account, to act as a bank account ID:

```
type AccountKey = (Party, Text)

template Account with
  bank : Party
  number : Text
  owner : Party
  balance : Decimal
  observers : [Party]
where
  signatory [bank, owner]
  observer observers

  key (bank, number) : AccountKey
  maintainer key._1
```

45.2.11.1 What Can Be a Contract Key

The key can be an arbitrary serializable expression that does **not** contain contract IDs. However, it **must** include every party that you want to use as a maintainer (see [Specify Maintainers](#) below).

It's best to use simple types for your keys like `Text` or `Int`, rather than a list or more complex type.

45.2.11.2 Specify Maintainers

If you specify a contract key for a template, you must also specify a `maintainer` or maintainers, in a similar way to specifying signatories or observers. The maintainers `own` the key in the same way the signatories `own` a contract. Just like signatories of contracts prevent double spends or use of false contract data, maintainers of keys prevent double allocation or incorrect lookups. Since the key is part of the contract, the maintainers **must** be signatories of the contract. However, maintainers are computed from the `key` instead of the template arguments. In the example above, the `bank` is ultimately the maintainer of the key.

Uniqueness of keys is guaranteed per template. Since multiple templates may use the same key type, some key-related functions must be annotated using the `@ContractType` as shown in the examples below.

When you are writing Daml models, the maintainers matter since they affect authorization - much like signatories and observers. You don't need to do anything to `maintain` the keys. In the above example, it is guaranteed that there can only be one `Account` with a given `number` at a given `bank`.

Checking of the keys is done automatically at execution time, by the Daml execution engine: if someone tries to create a new contract that duplicates an existing contract key, the execution engine will cause that creation to fail.

45.2.11.3 Contract Lookups

The primary purpose of contract keys is to provide a stable, and possibly meaningful, identifier that can be used in Daml to fetch contracts. There are two functions to perform such lookups: `fetchByKey` and `lookupByKey`. Both types of lookup are performed at interpretation time on the submitting Participant Node, on a best-effort basis. Currently, that best-effort means lookups only return contracts if the submitting Party is a stakeholder of that contract.

In particular, the above means that if multiple commands are submitted simultaneously, all using contract lookups to find and consume a given contract, there will be contention between these commands, and at most one will succeed. For more information, see the section on [Avoiding Contention](#).

Limiting key usage to stakeholders also means that keys cannot be used to access a divulged contract, i.e. there can be cases where `fetch` succeeds and `fetchByKey` does not. See the example at the end of this section for details.

`fetchByKey`

```
(fetchedContractId, fetchedContract) <- fetchByKey @ContractType contractKey
```

Use `fetchByKey` to fetch the ID and data of the contract with the specified key. It is an alternative to `fetch` and behaves the same in most ways.

It returns a tuple of the ID and the contract object (containing all its data).

Like `fetch`, `fetchByKey` needs to be authorized by at least one stakeholder.

`fetchByKey` fails and aborts the transaction if:

- The submitting Party is not a stakeholder on a contract with the given key, or
- A contract was found, but the `fetchByKey` violates the authorization rule, meaning no stakeholder authorized the `fetch`.

This means that if it fails, it doesn't guarantee that a contract with that key doesn't exist, just that the submitting Party doesn't know about it, or there are issues with authorization.

`visibleByKey`

```
boolean <- visibleByKey @ContractType contractKey
```

Use `visibleByKey` to check whether you can see an active contract for the given key with the current authorizations. If the contract exists and you have permission to see it, returns `True`, otherwise returns `False`.

To clarify, ignoring contention:

1. `visibleByKey` will return `True` if all of these are true: there exists a contract for the given key, the submitter is a stakeholder on that contract, and at the point of call we have the authorization of **all** of the maintainers of the key.
2. `visibleByKey` will return `False` if all of those are true: there is no contract for the given key, and at the point of call we have authorization from **all** the maintainers of the key.
3. `visibleByKey` will abort the transaction at interpretation time if, at the point of call, we are missing the authorization from any one maintainer of the key.

4. `visibleByKey` will fail at validation time (after returning `False` at interpretation time) if all of these are true: at the point of call, we have the authorization of **all** the maintainers, and a valid contract exists for the given key, but the submitter is not a stakeholder on that contract.

While it may at first seem too restrictive to require **all** maintainers to authorize the call, this is actually required in order to validate negative lookups. In the positive case, when you can see the contract, it's easy for the transaction to mention which contract it found, and therefore for validators to check that this contract does indeed exist, and is active as of the time of executing the transaction.

For the negative case, however, the transaction submitted for execution cannot say *which* contract it has not found (as, by definition, it has not found it, and it may not even exist). Still, validators have to be able to reproduce the result of not finding the contract, and therefore they need to be able to look for it, which means having the authorization to ask the maintainers about it.

lookupByKey

```
optionalContractId <- lookupByKey @ContractType contractKey
```

Use `lookupByKey` to check whether a contract with the specified key exists. If it does exist, `lookupByKey` returns the `Some contractId`, where `contractId` is the ID of the contract; otherwise, it returns `None`.

`lookupByKey` is conceptually equivalent to

```
lookupByKey : forall c k. (HasFetchByKey c k) => k -> Update (Optional
↳ (ContractId c))
lookupByKey k = do
  visible <- visibleByKey @c k
  if visible then do
    (contractId, _ignoredContract) <- fetchByKey @c k
    return $ Some contractId
  else
    return None
```

Therefore, `lookupByKey` needs all the same authorizations as `visibleByKey`, for the same reasons, and fails in the same cases.

To get the data from the contract once you've confirmed it exists, you'll still need to use `fetch`.

45.2.11.4 exerciseByKey

```
exerciseByKey @ContractType contractKey
```

Use `exerciseByKey` to exercise a choice on a contract identified by its key (compared to `exercise`, which lets you exercise a contract identified by its `ContractId`). Just like `exercise`, running `exerciseByKey` requires visibility of the contract (either through divulgence, `readAs` or being a stakeholder) and authorization from the controllers of the choice.

45.2.11.5 Example

A complete example of possible success and failure scenarios of `fetchByKey` and `lookupByKey` is shown below.

45.2.12 Reference: Exceptions

Exceptions are a Daml feature which provides a way to handle certain errors that arise during interpretation instead of aborting the transaction, and to roll back the state changes that lead to the error.

There are two types of errors:

45.2.12.1 Builtin Errors

Exception type	Thrown on
GeneralError	Calls to <code>error</code> and <code>abort</code>
ArithmeticError	Arithmetic errors like overflows and division by zero
PreconditionFailed	ensure statements that return <code>False</code>
AssertionFailed	Failed <code>assert</code> calls (or other functions from <code>DA.Assert</code>)

Note that other errors cannot be handled via exceptions, e.g., an exercise on an inactive contract will still result in a transaction abort.

45.2.12.2 User-defined Exceptions

Users can define their own exception types which can be thrown and caught. The definition looks similar to templates, and just like with templates, the definition produces a record type of the given name as well as instances to make that type throwable and catchable.

In addition to the record fields, exceptions also need to define a `message` function.

```

exception MyException
  with
    field1 : Int
    field2 : Text
  where
    message "MyException(" <> show field1 <> ", " <> show field2 <> ")"

```

45.2.12.3 Throw Exceptions

There are two ways to throw exceptions:

1. Inside of an `Action` like `Update` or `Script` you can use `throw` from `DA.Exception`. This works for any `Action` that is an instance of `ActionThrow`.
2. Outside of `ActionThrow` you can throw exceptions using `throwPure`.

If both are an option, it is generally preferable to use `throw` since it is easier to reason about when exactly the exception will get thrown.

45.2.12.4 Catch Exceptions

Exceptions are caught in try-catch blocks similar to those found in languages like Java. The `try` block defines the scope within which errors should be handled while the `catch` clauses defines which types of errors are handled and how the program should continue. If an exception gets caught, the subtransaction between the `try` and the the point where the exception is thrown is rolled back. The actions under rollback nodes are still validated, so, e.g., you can never fetch a contract that is inactive at that point or have two contracts with the same key active at the same time. However, all ledger state changes (creates, consuming exercises) are rolled back to the state before the rollback node.

Each try-catch block can have multiple `catch` clauses with the first one that applies taking precedence.

In the example below the `create` of `T` will be rolled back and the first `catch` clause applies which will create an `Error` contract.

```
try do
  _ <- create (T p)
  throw MyException with
    field1 = 0
    field2 = "42"
catch
  (MyException field1 field2) ->
    create Error with
      p = p
      msg = "MyException"
  (ArithmeticError _) ->
    create Error with
      p = p
      msg = "ArithmeticError"
```

45.2.13 Reference: Interfaces

In Daml, an interface defines an abstract type together with a behavior specified by its view type, method signatures, and choices. For a template to conform to this interface, there must be a corresponding `interface` `instance` definition where all the methods of the interface (including the special `view` method) are implemented. This allows decoupling such behavior from its implementation, so other developers can write applications in terms of the interface instead of the concrete template.

45.2.13.1 Configuration

To use this feature your Daml project must target Daml-LF version 1.15 or higher, which is the current default.

If using Canton, the protocol version of the sync domain should be 4 or higher, see [Canton protocol version](#) for more details.

45.2.13.2 Interface Declaration

An interface declaration is somewhat similar to a template declaration.

Interface Name

```
interface MyInterface where
```

This is the name of the interface.

It's preceded by the keyword `interface` and followed by the keyword `where`.

It must begin with a capital letter, like any other type name.

Implicit abstract type

Whenever an interface is defined, an abstract type is defined with the same name. Abstract here means:

- Values of this type cannot be created using a data constructor. Instead, they are constructed by applying the function `toInterface` to a template value.
- Values of this type cannot be inspected directly via case analysis. Instead, use functions such as `fromInterface`.
- See [Interface Functions](#) for more information on these and other functions for interacting with interface values.

An interface value carries inside it the type and parameters of the template value from which it was constructed.

As for templates, the existence of a local binding `b` of type `I`, where `I` is an interface does not necessarily imply the existence on the ledger of a contract with the template type and parameters used to construct `b`. This can only be assumed if `b` the result of a fetch from the ledger within the same transaction.

Interface Methods

```
method1 : Party
method2 : Int
method3 : Bool -> Int -> Int -> Int
```

An interface may define any number of methods.

A method definition consists of the method name and the method type, separated by a single colon `:`. The name of the method must be a valid identifier beginning with a lowercase letter or an underscore.

A method definition introduces a top level function of the same name:

- If the interface is called I , the method is called m , and the method type is M (which might be a function type), this introduces the function $m : I \rightarrow M$:

```
func1 : MyInterface -> Party
func1 = method1

func2 : MyInterface -> Int
func2 = method2

func3 : MyInterface -> Bool -> Int -> Int -> Int
func3 = method3
```

- The first argument's type I means that the function can only be applied to values of the interface type I itself. Methods cannot be applied to template values, even if there exists an interface instance of I for that template. To use an interface method on a template value, first convert it using the `toInterface` function.
- Applying the function to such argument results in a value of type M , corresponding to the implementation of m in the interface instance of I for the underlying template type t (the type of the template value from which the interface value was constructed).

One special method, `view`, must be defined for the viewtype. (see [Interface View Type](#) below).

Interface View Type

```
data MyInterfaceViewType =
  MyInterfaceViewType { name : Text, value : Int }
```

```
viewtype MyInterfaceViewType
```

All interface instances must implement a special `view` method which returns a value of the type declared by `viewtype`.

The type must be a record.

This type is returned by subscriptions on interfaces.

Interface Choices

```
choice MyChoice : (ContractId MyInterface, Int)
  with
    argument1 : Bool
    argument2 : Int
  controller method1 this
  do
    let n0 = method2 this
    let n1 = method3 this argument1 argument2 n0
    pure (self, n1)

nonconsuming choice MyNonConsumingChoice : Int
  controller method1 this
  do
    pure $ method2 this
```

Interface choices work in a very similar way to template choices. Any contract of a template type for which an interface instance exists will grant the choice to the controlling party.

Interface choices can only be exercised on values of the corresponding interface type. To exercise an interface choice on a template value, first convert it using the `toInterface` function. Interface methods can be used to define the controller of a choice (e.g. `method1`) as well as the actions that run when the choice is exercised (e.g. `method2` and `method3`).

As for template choices, the `choice` keyword can be optionally prefixed with the `nonconsuming` keyword to specify that the contract will not be consumed when the choice is exercised. If not specified, the choice will be `consuming`. Note that the `preconsuming` and `postconsuming` qualifiers are not supported on interface choices.

See [Reference: Choices](#) for full reference information, but note that controller-first syntax is not supported for interface choices.

Empty Interfaces

```
data EmptyInterfaceView = EmptyInterfaceView {}

interface YourInterface where
  viewtype EmptyInterfaceView
```

It is possible (though not necessarily useful) to define an interface without methods, precondition or choices. However, a view type must always be defined, though it can be set to `unit`.

45.2.13.3 Interface Instances

For context, a simple template definition:

```
template NameOfTemplate
  with
    field1 : Party
    field2 : Int
  where
    signatory field1
```

interface instance clause

```
interface instance MyInterface for NameOfTemplate where
  view = MyInterfaceViewType "NameOfTemplate" 100
  method1 = field1
  method2 = field2
  method3 False __ = 0
  method3 True x y
    | x > 0 = x + y
    | otherwise = y
```

To make a template an instance of an existing interface, an `interface instance` clause must be defined in the template declaration.

The template of the clause must match the enclosing declaration. In other words, a template `T` declaration can only contain `interface instance` clauses where the template is `T`.

The clause must start with the keywords `interface instance`, followed by the name of the interface, then the keyword `for` and the name of the template, and finally the keyword `where`, which introduces a block where **all** the methods of the interface must be implemented.

Within the clause, there's an implicit local binding `this` referring to the contract on which the method is applied, which has the type of the template's data record. The template parameters of this contract are also in scope.

Method implementations can be defined using the same syntax as for top level functions, including pattern matches and guards (e.g. `method3`).

Each method implementation must return the same type as specified for that method in the interface declaration.

The implementation of the special `view` method must return the type specified as the `view-type` in the interface declaration.

`interface instance` clause in the interface

```
interface MyNewInterface where
  viewtype EmptyInterfaceView
  myNewMethod1 : Party
  myNewMethod2 : Int -> Int

  choice MyNewChoice : Int
    controller myNewMethod1 this
    do pure $ myNewMethod2 this 0

  interface instance MyNewInterface for NameOfTemplate where
    view = EmptyInterfaceView
    myNewMethod1 = field1
    myNewMethod2 x = field2 `min` x
```

To make an *existing* template an instance of a new interface, the `interface instance` clause must be defined in the *interface* declaration.

In this case, the *interface* of the clause must match the enclosing declaration. In other words, an interface `I` declaration can only contain `interface instance` clauses where the interface is `I`.

All other rules for `interface instance` clauses are the same whether the enclosing declaration is a template or an interface. In particular, the implicit local binding `this` always has the type of the *template's* record.

`Empty interface instance` clause

If the interface has no methods, the interface instance only needs to implement the `view` method:

```
interface instance YourInterface for NameOfTemplate where
  view = EmptyInterfaceView
```

45.2.13.4 Interface Functions

`interfaceTypeRep`

Type	<pre>HasInterfaceTypeRep i => i -> TemplateTypeRep</pre>
Instantiated Type	<code>MyInterface -> TemplateTypeRep</code>
Notes	The value of the resulting <code>TemplateTypeRep</code> indicates what template was used to construct the interface value.

`toInterface`

Type	<pre>forall i t. HasToInterface t i => t -> i</pre>
Instantiated Type	<code>MyTemplate -> MyInterface</code>
Notes	Converts a template value into an interface value.

`fromInterface`

Type	<pre>HasFromInterface t i => i -> Optional t</pre>
Instantiated Type	<code>MyInterface -> Optional MyTemplate</code>
Notes	Attempts to convert an interface value back into a template value. The result is <code>None</code> if the expected template type doesn't match the underlying template type used to construct the contract.

`toInterfaceContractId`

Type	<pre>forall i t. HasToInterface t i => ContractId t -> ContractId i</pre>
Instantiated Type	<pre>ContractId MyTemplate -> ContractId MyInterface</pre>
Notes	Converts a template Contract ID into an Interface Contract ID.

`fromInterfaceContractId`

Type	<pre>forall t i. HasFromInterface t i => ContractId i -> ContractId t</pre>
Instantiated Type	<pre>ContractId MyInterface -> Contract- tId MyTemplate</pre>
Notes	Converts an interface contract id into a template contract id. This function does not verify that the given contract id actually points to a contract of the resulting type; if that is not the case, a subsequent <code>fetch</code> , <code>exercise</code> or <code>archive</code> will fail. Therefore, this should only be used when the underlying contract is known to be of the resulting type, or when the result is immediately used by a <code>fetch</code> , <code>exercise</code> or <code>archive</code> action and a transaction failure is the desired behavior in case of mismatch. In all other cases, consider using <code>fetchFromInterface</code> instead.

`coerceInterfaceContractId`

Type	<pre>forall j i. (HasInterfaceTypeRep i, HasInterfaceTypeRep j) => ContractId i -> ContractId j</pre>
Instantiated Type	<pre>ContractId SourceInterface -> Con- tractId TargetInterface</pre>
Notes	<p>Converts an interface contract id into a contract id of a different interface. This function does not verify that the given contract id actually points to a contract of the resulting type; if that is not the case, a subsequent <code>fetch</code>, <code>exercise</code> or <code>archive</code> will fail. Therefore, this should only be used when the underlying contract is known to be of the resulting type, or when the result is immediately used by a <code>fetch</code>, <code>exercise</code> or <code>archive</code> action and a transaction failure is the desired behavior in case of mismatch.</p>

`fetchFromInterface`

Type	<pre>forall t i. (HasFromInterface t i, HasFetch i) => ContractId i -> Update (Optional (ContractId t, t))</pre>
Instantiated Type	<pre>ContractId MyInterface -> Update (Optional (ContractId MyTemplate, MyTemplate))</pre>
Notes	<p>Attempts to fetch and convert an interface contract id into a template, returning both the converted contract and its contract id if the conversion is successful, or <code>None</code> otherwise.</p>

45.2.13.5 Required Interfaces

```
interface OurInterface requires MyInterface, YourInterface where
  viewtype EmptyInterfaceView
```

An interface can depend on other interfaces. These are specified with the `requires` keyword after the interface name but before the `where` keyword, separated by commas.

For an interface declaration to be valid, its list of required interfaces must be transitively closed. In other words, an interface `I` cannot require an interface `J` without also explicitly requiring all the interfaces required by `J`. The order, however, is irrelevant.

For example, given

```
interface Shape where
  viewtype EmptyInterfaceView

interface Rectangle requires Shape where
  viewtype EmptyInterfaceView
```

This declaration for interface `Square` would cause a compiler error

```
-- Compiler error! "Interface Square is missing requirement [Shape]"
interface Square requires Rectangle where
  viewtype EmptyInterfaceView
```

Explicitly adding `Shape` to the required interfaces fixes the error

```
interface Square requires Rectangle, Shape where
  viewtype EmptyInterfaceView
```

For a template `T` to be a valid interface instance of an interface `I`, `T` must also be an interface instance of each of the interfaces required by `I`.

Interface Functions

Function	Notes
<code>toInterface</code>	Can also be used to convert an interface value to one of its required interfaces.
<code>fromInterface</code>	Can also be used to convert a value of an interface type to one of its requiring interfaces.
<code>toInterface-ContractId</code>	Can also be used to convert an interface contract id into a contract id of one of its required interfaces.
<code>fromInterfaceContractId</code>	Can also be used to convert an interface contract id into a contract id of one of its requiring interfaces.
<code>fetch-FromInterface</code>	Can also be used to fetch and convert an interface contract id into a contract and contract id of one of its requiring interfaces.

45.3 The Standard Library

The Daml standard library is a collection of Daml modules that are bundled with the SDK, and can be used to implement Daml applications.

The [Prelude](#) module is imported automatically in every Daml module. Other modules must be imported manually, just like your own project's modules. For example:

```
import DA.Optional
import DA.Time
```

Here is a complete list of modules in the standard library:

45.3.1 Prelude

The pieces that make up the Daml language.

45.3.1.1 Typeclasses

class [Action](#) m => [CanAssert](#) m **where**

Constraint that determines whether an assertion can be made in this context.

[assertFail](#) : [Text](#) -> m t

Abort since an assertion has failed. In an [Update](#), [Scenario](#), [Script](#), or [Trigger](#) context this will throw an [AssertionFailed](#) exception. In an [Either Text](#) context, this will return the message as an error.

instance [CanAssert](#) [Scenario](#)

instance [CanAssert](#) [Update](#)

instance [CanAssert](#) ([Either Text](#))

class [HasInterfaceTypeRep](#) i **where**

(Daml-LF >= 1.15) Exposes the [interfaceTypeRep](#) function. Available only for interfaces.

class [HasToInterface](#) t i **where**

(Daml-LF >= 1.15) Exposes the [toInterface](#) and [toInterfaceContractId](#) functions.

class [HasFromInterface](#) t i **where**

(Daml-LF >= 1.15) Exposes [fromInterface](#) and [fromInterfaceContractId](#) functions.

[fromInterface](#) : i -> [Optional](#) t

(Daml-LF >= 1.15) Attempt to convert an interface value back into a template value. A [None](#) indicates that the expected template type doesn't match the underlying template type for the interface value.

For example, `fromInterface @MyTemplate value` will try to convert the interface value `value` into the template type `MyTemplate`.

class [HasInterfaceView](#) i v **where**

[_view](#) : i -> v

class [HasTime](#) m **where**

The `HasTime` class is for where the time is available: `Scenario` and `Update`.

`getTime` : `HasCallStack` => `m Time`

Get the current time.

instance `HasTime Scenario`

instance `HasTime Update`

class `Action m` => `CanAbort m` **where**

The `CanAbort` class is for `Action s` that can be aborted.

`abort` : `Text` -> `m a`

Abort the current action with a message.

instance `CanAbort Scenario`

instance `CanAbort Update`

instance `CanAbort (Either Text)`

class `HasSubmit m cmds` **where**

`submit` : `HasCallStack` => `Party` -> `cmds a` -> `m a`

`submit p cmds` submits the commands `cmds` as a single transaction from party `p` and returns the value returned by `cmds`.

If the transaction fails, `submit` also fails.

`submitMustFail` : `HasCallStack` => `Party` -> `cmds a` -> `m ()`

`submitMustFail p cmds` submits the commands `cmds` as a single transaction from party `p`.

It only succeeds if the submitting the transaction fails.

instance `HasSubmit Scenario Update`

class `Functor f` => `Applicative f` **where**

`pure` : `a` -> `f a`

Lift a value.

`<*>` : `f (a -> b)` -> `f a` -> `f b`

Sequentially apply the function.

A few functors support an implementation of `<*>` that is more efficient than the default one.

`liftA2` : `(a -> b -> c)` -> `f a` -> `f b` -> `f c`

Lift a binary function to actions.

Some functors support an implementation of `liftA2` that is more efficient than the default one. In particular, if `fmap` is an expensive operation, it is likely better to use `liftA2` than to `fmap` over the structure and then use `<*>`.

`(>*)` : `f a` -> `f b` -> `f b`

Sequence actions, discarding the value of the first argument.

`(<*)` : `f a` -> `f b` -> `f a`

Sequence actions, discarding the value of the second argument.

instance `Applicative ((->) r)`

instance `Applicative (State s)`

instance *Applicative Down*
instance *Applicative Scenario*
instance *Applicative Update*
instance *Applicative Optional*
instance *Applicative Formula*
instance *Applicative NonEmpty*
instance *Applicative* (*Validation* err)
instance *Applicative* (*Either* e)
instance *Applicative* (*[]*)

class *Applicative* m => *Action* m **where**

(>>=) : m a -> (a -> m b) -> m b

Sequentially compose two actions, passing any value produced by the first as an argument to the second.

instance *Action* ((->) r)
instance *Action* (*State* s)
instance *Action Down*
instance *Action Scenario*
instance *Action Update*
instance *Action Optional*
instance *Action Formula*
instance *Action NonEmpty*
instance *Action* (*Either* e)
instance *Action* (*[]*)

class *Action* m => *ActionFail* m **where**

This class exists to desugar pattern matches in do-notation. Polymorphic usage, or calling `fail` directly, is not recommended. Instead consider using `CanAbort`.

fail : *Text* -> m a

Fail with an error message.

instance *ActionFail Scenario*
instance *ActionFail Update*
instance *ActionFail Optional*
instance *ActionFail* (*Either Text*)
instance *ActionFail* (*[]*)

class *Semigroup* a **where**

The class of semigroups (types with an associative binary operation).

(<>) : a -> a -> a

An associative operation.

instance *Ord* k => *Semigroup* (*Map* k v)

instance *Semigroup* (*TextMap* b)

instance *Semigroup* *All*

instance *Semigroup* *Any*

instance *Semigroup* (*Endo* a)

instance *Multiplicative* a => *Semigroup* (*Product* a)

instance *Additive* a => *Semigroup* (*Sum* a)

instance *Semigroup* (*NonEmpty* a)

instance *Ord* a => *Semigroup* (*Max* a)

instance *Ord* a => *Semigroup* (*Min* a)

instance *Ord* k => *Semigroup* (*Set* k)

instance *Semigroup* (*Validation* err a)

instance *Semigroup* *Ordering*

instance *Semigroup* *Text*

instance *Semigroup* [a]

class *Semigroup* a => *Monoid* a **where**

The class of monoids (types with an associative binary operation that has an identity).

mempty : a

Identity of (<>)

mconcat : [a] -> a

Fold a list using the monoid. For example using `mconcat` on a list of strings would concatenate all strings to one lone string.

instance *Ord* k => *Monoid* (*Map* k v)

instance *Monoid* (*TextMap* b)

instance *Monoid* *All*

instance *Monoid* *Any*

instance *Monoid* (*Endo* a)

instance *Multiplicative* a => *Monoid* (*Product* a)

instance *Additive* a => *Monoid* (*Sum* a)

instance *Ord* k => *Monoid* (*Set* k)

instance *Monoid* *Ordering*

instance *Monoid* *Text*

instance *Monoid* [a]

class *HasSignatory* t **where**

Exposes `signatory` function. Part of the `Template` constraint.

`signatory` : `t -> [Party]`

The signatories of a contract.

class `HasObserver` `t` **where**

Exposes `observer` function. Part of the `Template` constraint.

`observer` : `t -> [Party]`

The observers of a contract.

class `HasEnsure` `t` **where**

Exposes `ensure` function. Part of the `Template` constraint.

`ensure` : `t -> Bool`

A predicate that must be true, otherwise contract creation will fail.

class `HasAgreement` `t` **where**

Exposes `agreement` function. Part of the `Template` constraint.

`agreement` : `t -> Text`

The agreement text of a contract.

class `HasCreate` `t` **where**

Exposes `create` function. Part of the `Template` constraint.

`create` : `t -> Update (ContractId t)`

Create a contract based on a template `t`.

class `HasFetch` `t` **where**

Exposes `fetch` function. Part of the `Template` constraint.

`fetch` : `ContractId t -> Update t`

Fetch the contract data associated with the given contract ID. If the `ContractId t` supplied is not the contract ID of an active contract, this fails and aborts the entire transaction.

class `HasSoftFetch` `t` **where**

Exposes `softFetch` function

class `HasSoftExercise` `t c r` **where**

class `HasArchive` `t` **where**

Exposes `archive` function. Part of the `Template` constraint.

`archive` : `ContractId t -> Update ()`

Archive the contract with the given contract ID.

class `HasTemplateTypeRep` `t` **where**

Exposes `templateTypeRep` function in Daml-LF 1.7 or later. Part of the `Template` constraint.

class `HasToAnyTemplate` `t` **where**

Exposes `toAnyTemplate` function in Daml-LF 1.7 or later. Part of the `Template` constraint.

class *HasFromAnyTemplate* *t* **where**

Exposes `fromAnyTemplate` function in Daml-LF 1.7 or later. Part of the `Template` constraint.

class *HasExercise* *t c r* **where**

Exposes `exercise` function. Part of the `Choice` constraint.

exercise : *ContractId t* -> *c* -> *Update r*

Exercise a choice on the contract with the given contract ID.

class *HasDynamicExercise* *t c r* **where****class** *HasChoiceController* *t c* **where**

Exposes `choiceController` function. Part of the `Choice` constraint.

class *HasChoiceObserver* *t c* **where**

Exposes `choiceObserver` function. Part of the `Choice` constraint.

class *HasExerciseGuarded* *t c r* **where**

(1.dev only) Exposes `exerciseGuarded` function. Only available for interface choices.

exerciseGuarded : (*t* -> *Bool*) -> *ContractId t* -> *c* -> *Update r*

(1.dev only) Exercise a choice on the contract with the given contract ID, only if the predicate returns `True`.

class *HasToAnyChoice* *t c r* **where**

Exposes `toAnyChoice` function for Daml-LF 1.7 or later. Part of the `Choice` constraint.

class *HasFromAnyChoice* *t c r* **where**

Exposes `fromAnyChoice` function for Daml-LF 1.7 or later. Part of the `Choice` constraint.

class *HasKey* *t k* **where**

Exposes `key` function. Part of the `TemplateKey` constraint.

key : *t* -> *k*

The key of a contract.

class *HasLookupByKey* *t k* **where**

Exposes `lookupByKey` function. Part of the `TemplateKey` constraint.

lookupByKey : *k* -> *Update (Optional (ContractId t))*

Look up the contract ID *t* associated with a given contract key *k*.

You must pass the *t* using an explicit type application. For instance, if you want to look up a contract of template `Account` by its key *k*, you must call `lookupByKey @Account k`.

class *HasFetchByKey* *t k* **where**

Exposes `fetchByKey` function. Part of the `TemplateKey` constraint.

fetchByKey : *k* -> *Update (ContractId t, t)*

Fetch the contract ID and contract data associated with a given contract key.

You must pass the *t* using an explicit type application. For instance, if you want to fetch a contract of template `Account` by its key *k*, you must call `fetchByKey @Account k`.

class *HasMaintainer* *t k* **where**

Exposes `maintainer` function. Part of the `TemplateKey` constraint.

class *HasToAnyContractKey* *t k* **where**

Exposes `toAnyContractKey` function in Daml-LF 1.7 or later. Part of the `TemplateKey` constraint.

class *HasFromAnyContractKey* *t k* **where**

Exposes `fromAnyContractKey` function in Daml-LF 1.7 or later. Part of the `TemplateKey` constraint.

class *HasExerciseByKey* *t k c r* **where**

Exposes `exerciseByKey` function.

class *IsParties* *a* **where**

Accepted ways to specify a list of parties: either a single party, or a list of parties.

toParties : *a* -> [*Party*]

Convert to list of parties.

instance *IsParties* *Party*

instance *IsParties* (*Optional Party*)

instance *IsParties* (*NonEmpty Party*)

instance *IsParties* (*Set Party*)

instance *IsParties* [*Party*]

class *Functor* *f* **where**

A `Functor` is a typeclass for things that can be mapped over (using its `fmap` function. Examples include `Optional`, `[]` and `Update`).

fmap : (*a* -> *b*) -> *f* *a* -> *f* *b*

`fmap` takes a function of type `a -> b`, and turns it into a function of type `f a -> f b`, where `f` is the type which is an instance of `Functor`.

For example, `map` is an `fmap` that only works on lists. It takes a function `a -> b` and a `[a]`, and returns a `[b]`.

(*<\$*) : *a* -> *f* *b* -> *f* *a*

Replace all locations in the input `f b` with the same value `a`. The default definition is `fmap . const`, but you can override this with a more efficient version.

class *Eq* *a* **where**

The `Eq` class defines equality (`==`) and inequality (`/=`). All the basic datatypes exported by the "Prelude" are instances of `Eq`, and `Eq` may be derived for any datatype whose constituents are also instances of `Eq`.

Usually, `==` is expected to implement an equivalence relationship where two values comparing equal are indistinguishable by "public" functions, with a "public" function being one not allowing to see implementation details. For example, for a type representing non-normalised natural numbers modulo 100, a "public" function doesn't make the difference between 1 and 201. It is expected to have the following properties:

Reflexivity: `x == x = True`

Symmetry: $x == y = y == x$

Transitivity: if $x == y$ & $y == z = \text{True}$, then $x == z = \text{True}$

Substitutivity: if $x == y = \text{True}$ and f is a "public" function whose return type is an instance of `Eq`, then $f\ x == f\ y = \text{True}$

Negation: $x /= y = \text{not } (x == y)$

Minimal complete definition: either `==` or `/=`.

`(==)` : $a \rightarrow a \rightarrow \text{Bool}$

`(/=)` : $a \rightarrow a \rightarrow \text{Bool}$

`instance (Eq a, Eq b) => Eq (Either a b)`

`instance Eq BigNumeric`

`instance Eq Bool`

`instance Eq Int`

`instance Eq (Numeric n)`

`instance Eq Ordering`

`instance Eq RoundingMode`

`instance Eq Text`

`instance Eq a => Eq [a]`

`instance Eq ()`

`instance (Eq a, Eq b, Eq c, Eq d, Eq e, Eq f, Eq g, Eq h, Eq i, Eq j, Eq k, Eq l) => Eq (a, b, c, d, e, f, g, h, i, j, k, l)`

`instance (Eq a, Eq b, Eq c, Eq d, Eq e, Eq f, Eq g, Eq h, Eq i, Eq j, Eq k, Eq l, Eq m) => Eq (a, b, c, d, e, f, g, h, i, j, k, l, m)`

`instance (Eq a, Eq b, Eq c, Eq d, Eq e, Eq f, Eq g, Eq h, Eq i, Eq j, Eq k, Eq l, Eq m, Eq n) => Eq (a, b, c, d, e, f, g, h, i, j, k, l, m, n)`

```
instance (Eq a, Eq b, Eq c, Eq d, Eq e, Eq f, Eq g, Eq h, Eq i, Eq j, Eq k, Eq l, Eq m, Eq n, Eq o) => Eq
(a, b, c, d, e, f, g, h, i, j, k, l, m, n, o)
```

```
class Eq a => Ord a where
```

The `Ord` class is used for totally ordered datatypes.

Instances of `Ord` can be derived for any user-defined datatype whose constituent types are in `Ord`. The declared order of the constructors in the data declaration determines the ordering in derived `Ord` instances. The `Ordering` datatype allows a single comparison to determine the precise ordering of two objects.

The Haskell Report defines no laws for `Ord`. However, `<=` is customarily expected to implement a non-strict partial order and have the following properties:

Transitivity: if `x <= y` && `y <= z` = `True`, then `x <= z` = `True`

Reflexivity: `x <= x` = `True`

Antisymmetry: if `x <= y` && `y <= x` = `True`, then `x == y` = `True`

Note that the following operator interactions are expected to hold:

1. `x >= y` = `y <= x`
2. `x < y` = `x <= y` && `x /= y`
3. `x > y` = `y < x`
4. `x < y` = `compare x y == LT`
5. `x > y` = `compare x y == GT`
6. `x == y` = `compare x y == EQ`
7. `min x y` == if `x <= y` then `x` else `y` = `'True'`
8. `max x y` == if `x >= y` then `x` else `y` = `'True'`

Minimal complete definition: either `compare` or `<=`. Using `compare` can be more efficient for complex types.

```
compare : a -> a -> Ordering
```

```
(<) : a -> a -> Bool
```

```
(<=) : a -> a -> Bool
```

```
(>) : a -> a -> Bool
```

```
(>=) : a -> a -> Bool
```

```
max : a -> a -> a
```

```
min : a -> a -> a
```

```
instance (Ord a, Ord b) => Ord (Either a b)
```

```
instance Ord BigNumeric
```

```
instance Ord Bool
```

```
instance Ord Int
```

```
instance Ord (Numeric n)
```

```
instance Ord Ordering
```

```
instance Ord RoundingMode
```

```
instance Ord Text
```

```
instance Ord a => Ord [a]

instance Ord ()

instance (Ord a, Ord b) => Ord (a, b)

instance (Ord a, Ord b, Ord c) => Ord (a, b, c)

instance (Ord a, Ord b, Ord c, Ord d) => Ord (a, b, c, d)

instance (Ord a, Ord b, Ord c, Ord d, Ord e) => Ord (a, b, c, d, e)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f) => Ord (a, b, c, d, e, f)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g) => Ord (a, b, c, d, e, f, g)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h) => Ord (a, b, c, d, e, f, g, h)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i) => Ord (a, b, c, d, e, f, g, h, i)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i, Ord j) => Ord (a, b, c, d, e, f, g, h, i, j)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i, Ord j, Ord k) => Ord (a, b, c, d, e, f, g, h, i, j, k)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i, Ord j, Ord k, Ord l) => Ord (a, b, c, d, e, f, g, h, i, j, k, l)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i, Ord j, Ord k, Ord l, Ord m) => Ord (a, b, c, d, e, f, g, h, i, j, k, l, m)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i, Ord j, Ord k, Ord l, Ord m, Ord n) => Ord (a, b, c, d, e, f, g, h, i, j, k, l, m, n)

instance (Ord a, Ord b, Ord c, Ord d, Ord e, Ord f, Ord g, Ord h, Ord i, Ord j, Ord k, Ord l, Ord m, Ord n, Ord o) => Ord (a, b, c, d, e, f, g, h, i, j, k, l, m, n, o)
```

class `NumericScale` `n` **where**

Is this a valid scale for the `Numeric` type?

This typeclass is used to prevent the creation of `Numeric` values with too large a scale. The scale controls the number of digits available after the decimal point, and it must be between 0 and 37 inclusive.

Thus the only available instances of this typeclass are `NumericScale 0` through `NumericScale 37`. This cannot be extended without additional compiler and runtime support. You cannot implement a custom instance of this typeclass.

If you have an error message in your code of the form "No instance for (`NumericScale n`)", this is probably caused by having a numeric literal whose scale cannot be inferred by the compiler. You can usually fix this by adding a type signature to the definition, or annotating the numeric literal directly (for example, instead of writing `3.14159` you can write `(3.14159 : Numeric 5)`).

numericScale : proxy `n` -> `Int`

Get the scale of a `Numeric` as an integer. For example, `numericScale (3.14159 : Numeric 5)` equals 5.

instance *NumericScale* 8

instance *NumericScale* 9

class *IsNumeric* t **where**

Types that can be represented by decimal literals in Daml.

fromNumeric : *NumericScale* m => *Numeric* m -> t

Convert from *Numeric*. Raises an error if the number can't be represented exactly in the target type.

fromBigNumeric : *BigNumeric* -> t

Convert from *BigNumeric*. Raises an error if the number can't be represented exactly in the target type.

instance *IsNumeric* *BigNumeric*

instance *NumericScale* n => *IsNumeric* (*Numeric* n)

class *Bounded* a **where**

Use the *Bounded* class to name the upper and lower limits of a type.

You can derive an instance of the *Bounded* class for any enumeration type. *minBound* is the first constructor listed in the data declaration and *maxBound* is the last.

You can also derive an instance of *Bounded* for single-constructor data types whose constituent types are in *Bounded*.

Ord is not a superclass of *Bounded* because types that are not totally ordered can still have upper and lower bounds.

minBound : a

maxBound : a

instance *Bounded* *Bool*

instance *Bounded* *Int*

class *Enum* a **where**

Use the *Enum* class to define operations on sequentially ordered types: that is, types that can be enumerated. *Enum* members have defined successors and predecessors, which you can get with the *succ* and *pred* functions.

Types that are an instance of class *Bounded* as well as *Enum* should respect the following laws:

Both *succ* *maxBound* and *pred* *minBound* should result in a runtime error.

fromEnum and *toEnum* should give a runtime error if the result value is not representable in the result type. For example, *toEnum* 7 : *Bool* is an error.

enumFrom and *enumFromThen* should be defined with an implicit bound, like this:

```
enumFrom      x      = enumFromTo      x maxBound
enumFromThen x y    = enumFromThenTo x y bound
  where
    bound | fromEnum y >= fromEnum x = maxBound
          | otherwise                = minBound
```

succ : a -> a

Returns the successor of the given value. For example, for numeric types, `succ` adds 1.

If the type is also an instance of `Bounded`, `succ maxBound` results in a runtime error.

pred : a -> a

Returns the predecessor of the given value. For example, for numeric types, `pred` subtracts 1.

If the type is also an instance of `Bounded`, `pred minBound` results in a runtime error.

toEnum : Int -> a

Convert a value from an `Int` to an `Enum` value: ie, `toEnum i` returns the item at the `i` th position of (the instance of) `Enum`

fromEnum : a -> Int

Convert a value from an `Enum` value to an `Int`: ie, returns the `Int` position of the element within the `Enum`.

If `fromEnum` is applied to a value that's too large to fit in an `Int`, what is returned is up to your implementation.

enumFrom : a -> [a]

Return a list of the `Enum` values starting at the `Int` position. For example:

```
enumFrom 6 : [Int] = [6,7,8,9,...,maxBound : Int]
```

enumFromThen : a -> a -> [a]

Returns a list of the `Enum` values with the first value at the first `Int` position, the second value at the second `Int` position, and further values with the same distance between them.

For example:

```
enumFromThen 4 6 : [Int] = [4,6,8,10...]
```

```
enumFromThen 6 2 : [Int] = [6,2,-2,-6,...,minBound :: Int]
```

enumFromTo : a -> a -> [a]

Returns a list of the `Enum` values with the first value at the first `Int` position, and the last value at the last `Int` position.

This is what's behind the language feature that lets you write `[n,m..]`.

For example:

```
enumFromTo 6 10 : [Int] = [6,7,8,9,10]
```

enumFromThenTo : a -> a -> a -> [a]

Returns a list of the `Enum` values with the first value at the first `Int` position, the second value at the second `Int` position, and further values with the same distance between them, with the final value at the final `Int` position.

This is what's behind the language feature that lets you write `[n,n'..m]`.

For example:

```
enumFromThenTo 4 2 -6 : [Int] = [4,2,0,-2,-4,-6]
```

```
enumFromThenTo 6 8 2 : [Int] = []
```

instance `Enum Bool`

instance `Enum Int`

class `Additive` **a where**

Use the `Additive` class for types that can be added. Instances have to respect the following laws:

(+) must be associative, ie: $(x + y) + z = x + (y + z)$

(+) must be commutative, ie: $x + y = y + x$

$x + \text{aunit} = x$

`negate` gives the additive inverse, ie: $x + \text{negate } x = \text{aunit}$

(+) : $a \rightarrow a \rightarrow a$

Add the two arguments together.

`aunit` : a

The additive identity for the type. For example, for numbers, this is 0.

(-) : $a \rightarrow a \rightarrow a$

Subtract the second argument from the first argument, ie. $x - y = x + \text{negate } y$

`negate` : $a \rightarrow a$

Negate the argument: $x + \text{negate } x = \text{aunit}$

instance *Additive* *BigNumeric*

instance *Additive* *Int*

instance *Additive* (*Numeric* n)

class *Multiplicative* a **where**

Use the *Multiplicative* class for types that can be multiplied. Instances have to respect the following laws:

(*) is associative, ie: $(x * y) * z = x * (y * z)$

(*) is commutative, ie: $x * y = y * x$

$x * \text{munit} = x$

(*) : $a \rightarrow a \rightarrow a$

Multiply the arguments together

`munit` : a

The multiplicative identity for the type. For example, for numbers, this is 1.

(^) : $a \rightarrow \text{Int} \rightarrow a$

$x \wedge n$ raises x to the power of n .

instance *Multiplicative* *BigNumeric*

instance *Multiplicative* *Int*

instance *Multiplicative* (*Numeric* n)

class (*Additive* a , *Multiplicative* a) => *Number* a **where**

Number is a class for numerical types. As well as the rules for *Additive* and *Multiplicative*, instances also have to respect the following law:

(*) is distributive with respect to (+). That is: $a * (b + c) = (a * b) + (a * c)$ and $(b + c) * a = (b * a) + (c * a)$

instance *Number* *BigNumeric*

instance *Number* *Int*

instance *Number* (*Numeric* n)

class *Signed* a **where**

The `Signed` is for the sign of a number.

signum : `a -> a`

Sign of a number. For real numbers, the 'signum' is either `-1` (negative), `0` (zero) or `1` (positive).

abs : `a -> a`

The absolute value: that is, the value without the sign.

instance `Signed BigNumeric`

instance `Signed Int`

instance `Signed (Numeric n)`

class `Multiplicative a => Divisible a where`

Use the `Divisible` class for types that can be divided. Instances should respect that division is the inverse of multiplication, i.e. `x * y / y` is equal to `x` whenever it is defined.

(/) : `a -> a -> a`

`x / y` divides `x` by `y`

instance `Divisible Int`

instance `Divisible (Numeric n)`

class `Divisible a => Fractional a where`

Use the `Fractional` class for types that can be divided and where the reciprocal is well defined. Instances have to respect the following laws:

When `recip x` is defined, it must be the inverse of `x` with respect to multiplication:

`x * recip x = munit`

When `recip y` is defined, then `x / y = x * recip y`

recip : `a -> a`

Calculates the reciprocal: `recip x` is `1/x`.

instance `Fractional (Numeric n)`

class `Show a where`

Use the `Show` class for values that can be converted to a readable `Text` value.

Derived instances of `Show` have the following properties:

The result of `show` is a syntactically correct expression that only contains constants (given the fixity declarations in force at the point where the type is declared). It only contains the constructor names defined in the data type, parentheses, and spaces. When labelled constructor fields are used, braces, commas, field names, and equal signs are also used.

If the constructor is defined to be an infix operator, then `showsPrec` produces infix applications of the constructor.

If the precedence of the top-level constructor in `x` is less than `d` (associativity is ignored), the representation will be enclosed in parentheses. For example, if `d` is `0` then the result is never surrounded in parentheses; if `d` is `11` it is always surrounded in parentheses, unless it is an atomic expression.

If the constructor is defined using record syntax, then `show` will produce the record-syntax form, with the fields given in the same order as the original declaration.

showsPrec : *Int* -> *a* -> *ShowS*

Convert a value to a readable `Text` value. Unlike `show`, `showsPrec` should satisfy the rule `showsPrec d x r ++ s == showsPrec d x (r ++ s)`

show : *a* -> *Text*

Convert a value to a readable `Text` value.

showList : [*a*] -> *ShowS*

Allows you to show lists of values.

instance (*Show* *a*, *Show* *b*) => *Show* (*Either* *a* *b*)

instance *Show* *BigNumeric*

instance *Show* *Bool*

instance *Show* *Int*

instance *Show* (*Numeric* *n*)

instance *Show* *Ordering*

instance *Show* *RoundingMode*

instance *Show* *Text*

instance *Show* *a* => *Show* [*a*]

instance *Show* ()

instance (*Show* *a*, *Show* *b*) => *Show* (*a*, *b*)

instance (*Show* *a*, *Show* *b*, *Show* *c*) => *Show* (*a*, *b*, *c*)

instance (*Show* *a*, *Show* *b*, *Show* *c*, *Show* *d*) => *Show* (*a*, *b*, *c*, *d*)

instance (*Show* *a*, *Show* *b*, *Show* *c*, *Show* *d*, *Show* *e*) => *Show* (*a*, *b*, *c*, *d*, *e*)

45.3.1.2 Data Types

data *AnyChoice*

Existential choice type that can wrap an arbitrary choice.

AnyChoice

Field	Type	Description
<code>getAnyChoice</code>	<code>Any</code>	
<code>getAnyChoiceTemplateTypeRep</code>	<i>TemplateTypeRep</i>	

instance *Eq* *AnyChoice*

instance *Ord* *AnyChoice*

data *AnyContractKey*

Existential contract key type that can wrap an arbitrary contract key.

AnyContractKey

Field	Type	Description
getAnyContractKey	Any	
getAnyContractKeyTemplateTypeRep	TemplateTypeRep	

instance [Eq AnyContractKey](#)

instance [Ord AnyContractKey](#)

data [AnyTemplate](#)

Existential template type that can wrap an arbitrary template.

[AnyTemplate](#)

Field	Type	Description
getAnyTemplate	Any	

instance [Eq AnyTemplate](#)

instance [Ord AnyTemplate](#)

data [TemplateTypeRep](#)

Unique textual representation of a template Id.

[TemplateTypeRep](#)

Field	Type	Description
getTemplateTypeRep	TypeRep	

instance [Eq TemplateTypeRep](#)

instance [Ord TemplateTypeRep](#)

data [Down a](#)

The `Down` type can be used for reversing sorting order. For example, `sortOn (\x -> Down x.field)` would sort by descending `field`.

[Down a](#)

instance [Action Down](#)

instance [Applicative Down](#)

instance [Functor Down](#)

instance [Eq a => Eq \(Down a\)](#)

instance [Ord a => Ord \(Down a\)](#)

instance [Show a => Show \(Down a\)](#)

type *Implements* *t i* = (*HasInterfaceTypeRep* *i*, *HasToInterface* *t i*, *HasFromInterface* *t i*)
(Daml-LF >= 1.15) Constraint that indicates that a template implements an interface.

data *AnyException*

A wrapper for all exception types.

instance *HasFromAnyException AnyException*

instance *HasMessage AnyException*

instance *HasToAnyException AnyException*

data *ContractId* *a*

The *ContractId a* type represents an ID for a contract created from a template *a*. You can use the ID to fetch the contract, among other things.

instance *Eq (ContractId a)*

instance *Ord (ContractId a)*

instance *Show (ContractId a)*

data *Date*

The *Date* type represents a date, for example `date 2007 Apr 5`.

instance *Eq Date*

instance *Ord Date*

instance *Bounded Date*

instance *Enum Date*

instance *Show Date*

data *Map* *a b*

The *Map a b* type represents an associative array from keys of type *a* to values of type *b*. It uses the built-in equality for keys. Import `DA.Map` to use it.

instance *Ord k => Foldable (Map k)*

instance *Ord k => Monoid (Map k v)*

instance *Ord k => Semigroup (Map k v)*

instance *Ord k => Traversable (Map k)*

instance *Ord k => Functor (Map k)*

instance (*Ord k*, *Eq v*) => *Eq (Map k v)*

instance (*Ord k*, *Ord v*) => *Ord (Map k v)*

instance (*Show k*, *Show v*) => *Show (Map k v)*

data *Party*

The *Party* type represents a party to a contract.

instance *IsParties Party*

instance *IsParties (Optional Party)*

instance *IsParties* (*NonEmpty Party*)

instance *IsParties* (*Set Party*)

instance *IsParties* [*Party*]

instance *Eq* *Party*

instance *Ord* *Party*

instance *Show* *Party*

data *Scenario* *a*

instance *CanAssert* *Scenario*

instance *ActionThrow* *Scenario*

instance *CanAbort* *Scenario*

instance *HasSubmit* *Scenario Update*

instance *HasTime* *Scenario*

instance *Action* *Scenario*

instance *ActionFail* *Scenario*

instance *Applicative* *Scenario*

instance *Functor* *Scenario*

data *TextMap* *a*

The *TextMap* *a* type represents an associative array from keys of type *Text* to values of type *a*.

instance *Foldable* *TextMap*

instance *Monoid* (*TextMap* *b*)

instance *Semigroup* (*TextMap* *b*)

instance *Traversable* *TextMap*

instance *Functor* *TextMap*

instance *Eq* *a* => *Eq* (*TextMap* *a*)

instance *Ord* *a* => *Ord* (*TextMap* *a*)

instance *Show* *a* => *Show* (*TextMap* *a*)

data *Time*

The *Time* type represents a specific datetime in UTC, for example *time* (date 2007 Apr 5) 14 30 05.

instance *Eq* *Time*

instance *Ord* *Time*

instance *Show* *Time*

data *Update* *a*

The `Update a` type represents an `Action` to update or query the ledger, before returning a value of type `a`. Examples include `create` and `fetch`.

instance `CanAssert Update`

instance `ActionCatch Update`

instance `ActionThrow Update`

instance `CanAbort Update`

instance `HasSubmit Scenario Update`

instance `HasTime Update`

instance `Action Update`

instance `ActionFail Update`

instance `Applicative Update`

instance `Functor Update`

data `Optional a`

The `Optional` type encapsulates an optional value. A value of type `Optional a` either contains a value of type `a` (represented as `Some a`), or it is empty (represented as `None`). Using `Optional` is a good way to deal with errors or exceptional cases without resorting to drastic measures such as `error`.

The `Optional` type is also an `Action`. It is a simple kind of error `Action`, where all errors are represented by `None`. A richer error `Action` could be built using the `Data.Either.Either` type.

`None`

`Some a`

instance `Foldable Optional`

instance `Action Optional`

instance `ActionFail Optional`

instance `Applicative Optional`

instance `IsParties (Optional Party)`

instance `Traversable Optional`

instance `Functor Optional`

instance `Eq a => Eq (Optional a)`

instance `Ord a => Ord (Optional a)`

instance `Show a => Show (Optional a)`

data `Archive`

The data type corresponding to the implicit `Archive` choice in every template.

`Archive`

(no fields)

instance *Eq* *Archive*

instance *Show* *Archive*

type *Choice* *t c r* = (*Template* *t*, *HasExercise* *t c r*, *HasToAnyChoice* *t c r*, *HasFromAnyChoice* *t c r*)
 Constraint satisfied by choices.

type *Template* *t* = (*HasTemplateTypeRep* *t*, *HasToAnyTemplate* *t*, *HasFromAnyTemplate* *t*)

type *TemplateKey* *t k* = (*Template* *t*, *HasKey* *t k*, *HasLookupByKey* *t k*, *HasFetchByKey* *t k*, *HasMaintainer* *t k*,
HasToAnyContractKey *t k*, *HasFromAnyContractKey* *t k*)
 Constraint satisfied by template keys.

data *Either* *a b*

The *Either* type represents values with two possibilities: a value of type *Either a b* is either *Left a* or *Right b*.

The *Either* type is sometimes used to represent a value which is either correct or an error; by convention, the *Left* constructor is used to hold an error value and the *Right* constructor is used to hold a correct value (mnemonic: "right" also means "correct").

Left *a*

Right *b*

instance (*Eq* *a*, *Eq* *b*) => *Eq* (*Either* *a b*)

instance (*Ord* *a*, *Ord* *b*) => *Ord* (*Either* *a b*)

instance (*Show* *a*, *Show* *b*) => *Show* (*Either* *a b*)

type *ShowS* = *Text* -> *Text*

showS should represent some text, and applying it to some argument should prepend the argument to the represented text.

data *BigNumeric*

A big numeric type, capable of holding large decimal values with many digits.

BigNumeric represents any positive or negative decimal number with up to 2¹⁵ digits before the decimal point, and up to 2¹⁵ digits after the decimal point.

BigNumeric is not serializable, it is only intended for intermediate computation. You must round and convert *BigNumeric* to a fixed-width numeric (*Numeric n*) in order to store it in a template. The rounding operations are *round* and *div* from the *DA.BigNumeric* module. The casting operations are *fromNumeric* and *fromBigNumeric* from the *IsNumeric* typeclass.

instance *Eq* *BigNumeric*

instance *IsNumeric* *BigNumeric*

instance *Ord* *BigNumeric*

instance *Additive* *BigNumeric*

instance *Multiplicative* *BigNumeric*

instance *Number* *BigNumeric*

instance *Signed* *BigNumeric*

instance *Show* *BigNumeric*

data *Bool*

A type for Boolean values, ie `True` and `False`.

False

True

instance *Eq Bool*

instance *Ord Bool*

instance *Bounded Bool*

instance *Enum Bool*

instance *Show Bool*

type *Decimal* = *Numeric* 10

data *Int*

A type representing a 64-bit integer.

instance *Eq Int*

instance *Ord Int*

instance *Bounded Int*

instance *Enum Int*

instance *Additive Int*

instance *Divisible Int*

instance *Multiplicative Int*

instance *Number Int*

instance *Signed Int*

instance *Show Int*

data *Nat*

(Kind) This is the kind of type-level naturals.

data *Numeric n*

A type for fixed-point decimal numbers, with the scale being passed as part of the type.

Numeric n represents a fixed-point decimal number with a fixed precision of 38 (i.e. 38 digits not including a leading zero) and a scale of *n*, i.e., *n* digits after the decimal point.

n must be between 0 and 37 (bounds inclusive).

Examples:

```
0.01  : Numeric 2
0.0001 : Numeric 4
```

instance *Eq (Numeric n)*

instance *NumericScale n => IsNumeric (Numeric n)*

instance *Ord (Numeric n)*

instance *Additive* (*Numeric* n)

instance *Divisible* (*Numeric* n)

instance *Fractional* (*Numeric* n)

instance *Multiplicative* (*Numeric* n)

instance *Number* (*Numeric* n)

instance *Signed* (*Numeric* n)

instance *Show* (*Numeric* n)

data *Ordering*

A type for giving information about ordering: being less than (*LT*), equal to (*EQ*), or greater than (*GT*) something.

LT

EQ

GT

instance *Eq Ordering*

instance *Ord Ordering*

instance *Show Ordering*

data *RoundingMode*

Rounding modes for *BigNumeric* operations like *div* and *round* from *DA.BigNumeric*.

RoundingUp

Round away from zero.

RoundingDown

Round towards zero.

RoundingCeiling

Round towards positive infinity.

RoundingFloor

Round towards negative infinity.

RoundingHalfUp

Round towards the nearest neighbor unless both neighbors are equidistant, in which case round away from zero.

RoundingHalfDown

Round towards the nearest neighbor unless both neighbors are equidistant, in which case round towards zero.

RoundingHalfEven

Round towards the nearest neighbor unless both neighbors are equidistant, in which case round towards the even neighbor.

RoundingUnnecessary

Do not round. Raises an error if the result cannot be represented without rounding at the targeted scale.

instance *Eq RoundingMode*

instance *Ord RoundingMode*

instance *Show RoundingMode*

data *Text*

A type for text strings, that can represent any unicode code point. For example "Hello, world".

instance *Eq Text*

instance *Ord Text*

instance *Show Text*

data *[] a*

A type for lists, for example `[1, 2, 3]`.

`()`

`(:)` `--`

45.3.1.3 Functions

assert : *CanAssert m => Bool -> m ()*

Check whether a condition is true. If it's not, abort the transaction.

assertMsg : *CanAssert m => Text -> Bool -> m ()*

Check whether a condition is true. If it's not, abort the transaction with a message.

assertAfter : *(CanAssert m, HasTime m) => Time -> m ()*

Check whether the given time is in the future. If it's not, abort the transaction.

assertBefore : *(CanAssert m, HasTime m) => Time -> m ()*

Check whether the given time is in the past. If it's not, abort the transaction.

daysSinceEpochToDate : *Int -> Date*

Convert from number of days since epoch (i.e. the number of days since January 1, 1970) to a date.

dateToDaysSinceEpoch : *Date -> Int*

Convert from a date to number of days from epoch (i.e. the number of days since January 1, 1970).

interfaceTypeRep : *HasInterfaceTypeRep i => i -> TemplateTypeRep*

(Daml-LF >= 1.15) Obtain the `TemplateTypeRep` for the template given in the interface value.

toInterface : *HasToInterface t i => t -> i*

(Daml-LF >= 1.15) Convert a template value into an interface value. For example `toInterface @MyInterface value` converts a template value into a `MyInterface` type.

toInterfaceContractId : *HasToInterface t i => ContractId t -> ContractId i*

(Daml-LF >= 1.15) Convert a template contract id into an interface contract id. For example, `toInterfaceContractId @MyInterface cid`.

fromInterfaceContractId : *HasFromInterface* t i => *ContractId* i -> *ContractId* t

(Daml-LF >= 1.15) Convert an interface contract id into a template contract id. For example, `fromInterfaceContractId @MyTemplate cid`.

Can also be used to convert an interface contract id into a contract id of one of its requiring interfaces.

This function does not verify that the interface contract id actually points to a template of the given type. This means that a subsequent `fetch`, `exercise`, or `archive` may fail, if, for example, the contract id points to a contract that implements the interface but is of a different template type than expected.

Therefore, you should only use `fromInterfaceContractId` in situations where you already know that the contract id points to a contract of the right template type. You can also use it in situations where you will fetch, exercise, or archive the contract right away, when a transaction failure is the appropriate response to the contract having the wrong template type.

In all other cases, consider using `fetchFromInterface` instead.

coerceInterfaceContractId : (*HasInterfaceTypeRep* i, *HasInterfaceTypeRep* j) => *ContractId* i -> *ContractId* j

(Daml-LF >= 1.15) Convert an interface contract id into a contract id of a different interface. For example, given two interfaces `Source` and `Target`, and `cid : ContractId Source`, `coerceInterfaceContractId @Target @Source cid : ContractId Target`.

This function does not verify that the contract id actually points to a contract that implements either interface. This means that a subsequent `fetch`, `exercise`, or `archive` may fail, if, for example, the contract id points to a contract of template A but it was coerced into a `ContractId B` where B is an interface and there's no interface instance B for A.

Therefore, you should only use `coerceInterfaceContractId` in situations where you already know that the contract id points to a contract of the right type. You can also use it in situations where you will fetch, exercise, or archive the contract right away, when a transaction failure is the appropriate response to the contract having the wrong type.

fetchFromInterface : (*HasFromInterface* t i, *HasFetch* i) => *ContractId* i -> *Update* (*Optional* (*ContractId* t, t))

(Daml-LF >= 1.15) Fetch an interface and convert it to a specific template type. If conversion is successful, this function returns the converted contract and its converted contract id. Otherwise, this function returns `None`.

Can also be used to fetch and convert an interface contract id into a contract and contract id of one of its requiring interfaces.

Example:

```
do
  fetchResult <- fetchFromInterface @MyTemplate ifaceCid
  case fetchResult of
    None -> abort "Failed to convert interface to appropriate template type"
    Some (tplCid, tpl) -> do
      ... do something with tpl and tplCid ...
```

_exerciseInterfaceGuard : a -> b -> c -> *Bool*

view : *HasInterfaceView* i v => i -> v

partyToText : *Party* -> *Text*

Convert the *Party* to *Text*, giving back what you passed to `getParty`. In most cases, you should use `show` instead. `show` wraps the party in 'ticks' making it clear it was a *Party* originally.

partyFromText : *Text* -> *Optional Party*

Converts a *Text* to *Party*. It returns `None` if the provided text contains any forbidden characters. See Daml-LF spec for a specification on which characters are allowed in parties. Note that

this function accepts text *without* single quotes.

This function does not check on whether the provided text corresponds to a party that "exists" on a given ledger: it merely converts the given `Text` to a `Party`. The only way to guarantee that a given `Party` exists on a given ledger is to involve it in a contract.

This function, together with `partyToText`, forms an isomorphism between valid party strings and parties. In other words, the following equations hold:

```
p. partyFromText (partyToText p) = Some p
txt p. partyFromText txt = Some p ==> partyToText p = txt
```

This function will crash at runtime if you compile Daml to Daml-LF < 1.2.

getParty : `Text` -> `Scenario Party`

coerceContractId : `ContractId a` -> `ContractId b`

Used to convert the type index of a `ContractId`, since they are just pointers. Note that subsequent fetches and exercises might fail if the template of the contract on the ledger doesn't match.

scenario : `Scenario a` -> `Scenario a`

curry : `((a, b) -> c) -> a -> b -> c`

Turn a function that takes a pair into a function that takes two arguments.

uncurry : `(a -> b -> c) -> (a, b) -> c`

Turn a function that takes two arguments into a function that takes a pair.

(>>) : `Action m => m a -> m b -> m b`

Sequentially compose two actions, discarding any value produced by the first. This is like sequencing operators (such as the semicolon) in imperative languages.

ap : `Applicative f => f (a -> b) -> f a -> f b`

Synonym for `<*>`.

return : `Applicative m => a -> m a`

Inject a value into the monadic type. For example, for `Update` and a value of type `a`, `return` would give you an `Update a`.

join : `Action m => m (m a) -> m a`

Collapses nested actions into a single action.

identity : `a -> a`

The identity function.

guard : `ActionFail m => Bool -> m ()`

foldl : `(b -> a -> b) -> b -> [a] -> b`

This function is a left fold, which you can use to inspect/analyse/consume lists. `foldl f i xs` performs a left fold over the list `xs` using the function `f`, using the starting value `i`.

Examples:

```
>>> foldl (+) 0 [1,2,3]
6

>>> foldl (^) 10 [2,3]
1000000
```

Note that `foldl` works from left-to-right over the list arguments.

find : `(a -> Bool) -> [a] -> Optional a`

`find p xs` finds the first element of the list `xs` where the predicate `p` is true. There might not be such an element, which is why this function returns an `Optional a`.

length : `[a] -> Int`

Gives the length of the list.

any : `(a -> Bool) -> [a] -> Bool`

Are there any elements in the list where the predicate is true? `any p xs` is `True` if `p` holds for at least one element of `xs`.

all : `(a -> Bool) -> [a] -> Bool`

Is the predicate true for all of the elements in the list? `all p xs` is `True` if `p` holds for every element of `xs`.

or : `[Bool] -> Bool`

Is at least one of elements in a list of `Bool` true? `or bs` is `True` if at least one element of `bs` is `True`.

and : `[Bool] -> Bool`

Is every element in a list of `Bool` true? `and bs` is `True` if every element of `bs` is `True`.

elem : `Eq a => a -> [a] -> Bool`

Does this value exist in this list? `elem x xs` is `True` if `x` is an element of the list `xs`.

notElem : `Eq a => a -> [a] -> Bool`

Negation of `elem`: `elem x xs` is `True` if `x` is not an element of the list `xs`.

(<\$>) : `Functor f => (a -> b) -> f a -> f b`

Synonym for `fmap`.

optional : `b -> (a -> b) -> Optional a -> b`

The `optional` function takes a default value, a function, and a `Optional` value. If the `Optional` value is `None`, the function returns the default value. Otherwise, it applies the function to the value inside the `Some` and returns the result.

Basic usage examples:

```
>>> optional False (> 2) (Some 3)
True
```

```
>>> optional False (> 2) None
False
```

```
>>> optional 0 (*2) (Some 5)
10
>>> optional 0 (*2) None
0
```

This example applies `show` to a `Optional Int`. If you have `Some n`, this shows the underlying `Int`, `n`. But if you have `None`, this returns the empty string instead of (for example) `None`:

```
>>> optional "" show (Some 5)
"5"
>>> optional "" show (None : Optional Int)
""
```

either : `(a -> c) -> (b -> c) -> Either a b -> c`

The `either` function provides case analysis for the `Either` type. If the value is `Left a`, it applies the first function to `a`; if it is `Right b`, it applies the second function to `b`.

Examples:

This example has two values of type `Either [Int] Int`, one using the `Left` constructor and another using the `Right` constructor. Then it applies either the `length` function (if it has a `[Int]`) or the "times-two" function (if it has an `Int`):

```
>>> let s = Left [1,2,3] : Either [Int] Int in either length (*2) s
3
>>> let n = Right 3 : Either [Int] Int in either length (*2) n
6
```

concat : `[[a]] -> [a]`

Take a list of lists and concatenate those lists into one list.

(++) : `[a] -> [a] -> [a]`

Concatenate two lists.

flip : `(a -> b -> c) -> b -> a -> c`

Flip the order of the arguments of a two argument function.

reverse : `[a] -> [a]`

Reverse a list.

mapA : `Applicative m => (a -> m b) -> [a] -> m [b]`

Apply an applicative function to each element of a list.

forA : `Applicative m => [a] -> (a -> m b) -> m [b]`

`forA` is `mapA` with its arguments flipped.

sequence : `Applicative m => [m a] -> m [a]`

Perform a list of actions in sequence and collect the results.

(=<<) : `Action m => (a -> m b) -> m a -> m b`

`=<<` is `>>=` with its arguments flipped.

concatMap : `(a -> [b]) -> [a] -> [b]`

Map a function over each element of a list, and concatenate all the results.

replicate : `Int -> a -> [a]`

`replicate i x` gives the list `[x, x, x, ..., x]` with `i` copies of `x`.

take : `Int -> [a] -> [a]`

Take the first `n` elements of a list.

drop : `Int -> [a] -> [a]`

Drop the first `n` elements of a list.

splitAt : `Int -> [a] -> ([a], [a])`

Split a list at a given index.

takeWhile : `(a -> Bool) -> [a] -> [a]`

Take elements from a list while the predicate holds.

dropWhile : `(a -> Bool) -> [a] -> [a]`

Drop elements from a list while the predicate holds.

span : `(a -> Bool) -> [a] -> ([a], [a])`

`span p xs` is equivalent to `(takeWhile p xs, dropWhile p xs)`.

partition : `(a -> Bool) -> [a] -> ([a], [a])`

The `partition` function takes a predicate, a list and returns the pair of lists of elements which do and do not satisfy the predicate, respectively; i.e.,

```
> partition p xs == (filter p xs, filter (not . p) xs)
```

```
>>> partition (<0) [1, -2, -3, 4, -5, 6]
([-2, -3, -5], [1, 4, 6])
```

break : (a -> Bool) -> [a] -> ([a], [a])

Break a list into two, just before the first element where the predicate holds. `break p xs` is equivalent to `span (not . p) xs`.

lookup : Eq a => a -> [(a, b)] -> Optional b

Look up the first element with a matching key.

enumerate : (Enum a, Bounded a) => [a]

Generate a list containing all values of a given enumeration.

zip : [a] -> [b] -> [(a, b)]

`zip` takes two lists and returns a list of corresponding pairs. If one list is shorter, the excess elements of the longer list are discarded.

zip3 : [a] -> [b] -> [c] -> [(a, b, c)]

`zip3` takes three lists and returns a list of triples, analogous to `zip`.

zipWith : (a -> b -> c) -> [a] -> [b] -> [c]

`zipWith` takes a function and two lists. It generalises `zip` by combining elements using the function, instead of forming pairs. If one list is shorter, the excess elements of the longer list are discarded.

zipWith3 : (a -> b -> c -> d) -> [a] -> [b] -> [c] -> [d]

`zipWith3` generalises `zip3` by combining elements using the function, instead of forming triples.

unzip : [(a, b)] -> ([a], [b])

Turn a list of pairs into a pair of lists.

unzip3 : [(a, b, c)] -> ([a], [b], [c])

Turn a list of triples into a triple of lists.

traceRaw : Text -> a -> a

`traceRaw msg a` prints `msg` and returns `a`, for debugging purposes.

Note that on some ledgers, those messages are not displayed at the default log level. For Sandbox, you can use `--log-level=debug` to include them.

trace : Show b => b -> a -> a

`trace b a` prints `b` and returns `a`, for debugging purposes.

Note that on some ledgers, those messages are not displayed at the default log level. For Sandbox, you can use `--log-level=debug` to include them.

traceld : Show b => b -> b

`traceld a` prints `a` and returns `a`, for debugging purposes.

Note that on some ledgers, those messages are not displayed at the default log level. For Sandbox, you can use `--log-level=debug` to include them.

debug : (Show b, Action m) => b -> m ()

`debug x` prints `x` for debugging purposes.

Note that on some ledgers, those messages are not displayed at the default log level. For Sandbox, you can use `--log-level=debug` to include them.

debugRaw : *Action* m => *Text* -> m ()

`debugRaw msg` prints `msg` for debugging purposes.

Note that on some ledgers, those messages are not displayed at the default log level. For Sandbox, you can use `--log-level=debug` to include them.

fst : (a, b) -> a

Return the first element of a tuple.

snd : (a, b) -> b

Return the second element of a tuple.

truncate : *Numeric* n -> *Int*

`truncate x` rounds `x` toward zero.

intToNumeric : *NumericScale* n => *Int* -> *Numeric* n

Convert an *Int* to a *Numeric*.

intToDecimal : *Int* -> *Decimal*

Convert an *Int* to a *Decimal*.

roundBankers : *Int* -> *Numeric* n -> *Numeric* n

Bankers' Rounding: `roundBankers dp x` rounds `x` to `dp` decimal places, where a `.5` is rounded to the nearest even digit.

roundCommercial : *NumericScale* n => *Int* -> *Numeric* n -> *Numeric* n

Commercial Rounding: `roundCommercial dp x` rounds `x` to `dp` decimal places, where a `.5` is rounded away from zero.

zero : *NumericScale* n => *Numeric* n

half : *NumericScale* n => *Numeric* n

round : *NumericScale* n => *Numeric* n -> *Int*

Round a *Decimal* to the nearest integer, where a `.5` is rounded away from zero.

floor : *NumericScale* n => *Numeric* n -> *Int*

Round a *Decimal* down to the nearest integer.

ceiling : *NumericScale* n => *Numeric* n -> *Int*

Round a *Decimal* up to the nearest integer.

null : [a] -> *Bool*

Is the list empty? `null xs` is true if `xs` is the empty list.

filter : (a -> *Bool*) -> [a] -> [a]

Filters the list using the function: keep only the elements where the predicate holds.

sum : *Additive* a => [a] -> a

Add together all the elements in the list.

product : *Multiplicative* a => [a] -> a

Multiply all the elements in the list together.

undefined : a

A convenience function that can be used to mark something not implemented. Always throws an error with "Not implemented."

softFetch : *HasSoftFetch* t => *ContractId* t -> *Update* t

softExercise : *HasSoftExercise* t c r => *ContractId* t -> c -> *Update* r

stakeholder : (*HasSignatory* t, *HasObserver* t) => t -> [*Party*]

The stakeholders of a contract: its signatories and observers.

maintainer : *HasMaintainer* t k => k -> [*Party*]

The list of maintainers of a contract key.

exerciseByKey : *HasExerciseByKey* t k c r => k -> c -> *Update* r

Exercise a choice on the contract associated with the given key.

You must pass the t using an explicit type application. For instance, if you want to exercise a choice *Withdraw* on a contract of template *Account* given by its key k, you must call `exerciseByKey @Account k Withdraw`.

createAndExercise : (*HasCreate* t, *HasExercise* t c r) => t -> c -> *Update* r

Create a contract and exercise the choice on the newly created contract.

templateTypeRep : *HasTemplateTypeRep* t => *TemplateTypeRep*

Generate a unique textual representation of the template id.

toAnyTemplate : *HasToAnyTemplate* t => t -> *AnyTemplate*

Wrap the template in *AnyTemplate*.

Only available for Daml-LF 1.7 or later.

fromAnyTemplate : *HasFromAnyTemplate* t => *AnyTemplate* -> *Optional* t

Extract the underlying template from *AnyTemplate* if the type matches or return *None*.

Only available for Daml-LF 1.7 or later.

toAnyChoice : (*HasTemplateTypeRep* t, *HasToAnyChoice* t c r) => c -> *AnyChoice*

Wrap a choice in *AnyChoice*.

You must pass the template type t using an explicit type application. For example `toAnyChoice @Account Withdraw`.

Only available for Daml-LF 1.7 or later.

fromAnyChoice : (*HasTemplateTypeRep* t, *HasFromAnyChoice* t c r) => *AnyChoice* -> *Optional* c

Extract the underlying choice from *AnyChoice* if the template and choice types match, or return *None*.

You must pass the template type t using an explicit type application. For example `fromAnyChoice @Account choice`.

Only available for Daml-LF 1.7 or later.

toAnyContractKey : (*HasTemplateTypeRep* t, *HasToAnyContractKey* t k) => k -> *AnyContractKey*

Wrap a contract key in *AnyContractKey*.

You must pass the template type t using an explicit type application. For example `toAnyContractKey @Proposal k`.

Only available for Daml-LF 1.7 or later.

fromAnyContractKey : (*HasTemplateTypeRep* t, *HasFromAnyContractKey* t k) => *AnyContractKey* -> *Optional* k

Extract the underlying key from *AnyContractKey* if the template and choice types match, or return *None*.

You must pass the template type t using an explicit type application. For example `fromAnyContractKey @Proposal k`.

Only available for Daml-LF 1.7 or later.

visibleByKey : *HasLookupByKey* t k => k -> *Update* *Bool*

True if contract exists, submitter is a stakeholder, and all maintainers authorize. False if contract does not exist and all maintainers authorize. Fails otherwise.

otherwise : *Bool*

Used as an alternative in conditions.

map : (a -> b) -> [a] -> [b]

`map f xs` applies the function `f` to all elements of the list `xs` and returns the list of results (in the same order as `xs`).

foldr : (a -> b -> b) -> b -> [a] -> b

This function is a right fold, which you can use to manipulate lists. `foldr f i xs` performs a right fold over the list `xs` using the function `f`, using the starting value `i`.

Note that `foldr` works from right-to-left over the list elements.

(.) : (b -> c) -> (a -> b) -> a -> c

Composes two functions, i.e., $(f \cdot g) \ x = f \ (g \ x)$.

const : a -> b -> a

`const x` is a unary function which evaluates to `x` for all inputs.

```
>>> const 42 "hello"
42
```

```
>>> map (const 42) [0..3]
[42, 42, 42, 42]
```

(\$) : (a -> b) -> a -> b

Take a function from `a` to `b` and a value of type `a`, and apply the function to the value of type `a`, returning a value of type `b`. This function has a very low precedence, which is why you might want to use it instead of regular function application.

(&&) : Bool -> Bool -> Bool

Boolean "and". This function has short-circuiting semantics, i.e., when both arguments are present and the first arguments evaluates to 'False', the second argument is not evaluated at all.

(||) : Bool -> Bool -> Bool

Boolean "or". This function has short-circuiting semantics, i.e., when both arguments are present and the first arguments evaluates to 'True', the second argument is not evaluated at all.

not : Bool -> Bool

Boolean "not"

error : Text -> a

Throws a `GeneralError` exception.

subtract : Additive a => a -> a -> a

`subtract x y` is equivalent to `y - x`.

This is useful for partial application, e.g., in `subtract 1` since `(- 1)` is interpreted as the number `-1` and not a function that subtracts `1` from its argument.

(%) : Int -> Int -> Int

`x % y` calculates the remainder of `x` by `y`

shows : Show a => a -> ShowS

showParen : Bool -> ShowS -> ShowS

Utility function that surrounds the inner `show` function with parentheses when the 'Bool' parameter is 'True'.

showString : *Text* -> *ShowS*

Utility function converting a ‘String’ to a show function that simply prepends the string unchanged.

showSpace : *ShowS*

Prepends a single space to the front of the string.

showCommaSpace : *ShowS*

Prepends a comma and a single space to the front of the string.

45.3.2 DA.Action

Action

45.3.2.1 Functions

when : *Applicative* f => *Bool* -> f () -> f ()

Conditional execution of *Action* expressions. For example,

```
when final (archive contractId)
```

will archive the contract `contractId` if the Boolean value `final` is `True`, and otherwise do nothing.

This function has short-circuiting semantics, i.e., when both arguments are present and the first arguments evaluates to `False`, the second argument is not evaluated at all.

unless : *Applicative* f => *Bool* -> f () -> f ()

The reverse of `when`.

This function has short-circuiting semantics, i.e., when both arguments are present and the first arguments evaluates to `True`, the second argument is not evaluated at all.

foldrA : *Action* m => (a -> b -> m b) -> b -> [a] -> m b

The `foldrA` is analogous to `foldr`, except that its result is encapsulated in an action. Note that `foldrA` works from right-to-left over the list arguments.

foldr1A : *Action* m => (a -> a -> m a) -> [a] -> m a

`foldr1A` is like `foldrA` but raises an error when presented with an empty list argument.

foldlA : *Action* m => (b -> a -> m b) -> b -> [a] -> m b

`foldlA` is analogous to `foldl`, except that its result is encapsulated in an action. Note that `foldlA` works from left-to-right over the list arguments.

foldl1A : *Action* m => (a -> a -> m a) -> [a] -> m a

The `foldl1A` is like `foldlA` but raises an errors when presented with an empty list argument.

filterA : *Applicative* m => (a -> m *Bool*) -> [a] -> m [a]

Filters the list using the applicative function: keeps only the elements where the predicate holds. Example: given a collection of iou contract IDs one can find only the GBPs.

```
filterA (fmap (\iou -> iou.currency == "GBP") . fetch) iouCids
```

replicateA : *Applicative* m => *Int* -> m a -> m [a]

`replicateA n act` performs the action `n` times, gathering the results.

replicateA_ : *Applicative* m => *Int* -> m a -> m ()

Like `replicateA`, but discards the result.

(>=>) : *Action* m => (a -> m b) -> (b -> m c) -> a -> m c

Left-to-right composition of Kleisli arrows.

(<=<) : *Action* m => (b -> m c) -> (a -> m b) -> a -> m c

Right-to-left composition of Kleisli arrows. @('>=>')@, with the arguments flipped.

45.3.3 DA.Action.State

DA.Action.State

45.3.3.1 Data Types

data *State* s a

A value of type *State* s a represents a computation that has access to a state variable of type s and produces a value of type a.

```
>>> runState (modify (+1)) 0 >>> ((), 1)
```

```
>>> evalState (modify (+1)) 0 >>> ()
```

```
>>> execState (modify (+1)) 0 >>> 1
```

```
>>> runState (do x <- get; modify (+1); pure x) 0 >>> (0, 1)
```

```
>>> runState (put 1) 0 >>> ((), 1)
```

```
>>> runState (modify (+1)) 0 >>> ((), 1)
```

Note that values of type *State* s a are not serializable.

State

Field	Type	Description
runState	s -> (a, s)	

instance *ActionState* s (*State* s)

instance *Action* (*State* s)

instance *Applicative* (*State* s)

instance *Functor* (*State* s)

45.3.3.2 Functions

evalState : *State* s a -> s -> a

Special case of *runState* that does not return the final state.

execState : *State* s a -> s -> s

Special case of *runState* that does only return the final state.

45.3.4 DA.Action.State.Class

DA.Action.State.Class

45.3.4.1 Typeclasses

class *ActionState* *s m* **where**

Action *m* has a state variable of type *s*.

Rules:

```
get  *> ma = ma
ma  <*> get = ma
put a >>= get = put a $> a
put a *> put b = put b
(,) <$> get <*> get = get <&> \a -> (a, a)
```

Informally, these rules mean it behaves like an ordinary assignable variable: it doesn't magically change value by looking at it, if you put a value there that's always the value you'll get if you read it, assigning a value but never reading that value has no effect, and so on.

get : *m s*

Fetch the current value of the state variable.

put : *s -> m ()*

Set the value of the state variable.

modify : (*s -> s*) -> *m ()*

Modify the state variable with the given function.

default *modify*

: *Action m => (s -> s) -> m ()*

instance *ActionState s (State s)*

45.3.5 DA.Assert

45.3.5.1 Functions

assertEq : (*CanAssert m, Show a, Eq a*) => *a -> a -> m ()*

Check two values for equality. If they're not equal, fail with a message.

(==) : (*CanAssert m, Show a, Eq a*) => *a -> a -> m ()*

Infix version of *assertEq*.

assertNotEq : (*CanAssert m, Show a, Eq a*) => *a -> a -> m ()*

Check two values for inequality. If they're equal, fail with a message.

(/=) : (*CanAssert m, Show a, Eq a*) => *a -> a -> m ()*

Infix version of *assertNotEq*.

assertAfterMsg : (*CanAssert m, HasTime m*) => *Text -> Time -> m ()*

Check whether the given time is in the future. If it's not, abort with a message.

assertBeforeMsg : (*CanAssert* m, *HasTime* m) => *Text* -> *Time* -> m ()

Check whether the given time is in the past. If it's not, abort with a message.

45.3.6 DA.Bifunctor

45.3.6.1 Typeclasses

class *Bifunctor* p **where**

A bifunctor is a type constructor that takes two type arguments and is a functor in both arguments. That is, unlike with *Functor*, a type constructor such as *Either* does not need to be partially applied for a *Bifunctor* instance, and the methods in this class permit mapping functions over the *Left* value or the *Right* value, or both at the same time.

It is a bifunctor where both the first and second arguments are covariant.

You can define a *Bifunctor* by either defining *bimap* or by defining both *first* and *second*.

If you supply *bimap*, you should ensure that:

```
`bimap identity identity` = `identity`
```

If you supply *first* and *second*, ensure:

```
first identity = identity
second identity = identity
```

If you supply both, you should also ensure:

```
bimap f g = first f . second g
```

By parametricity, these will ensure that:

```
bimap (f . g) (h . i) = bimap f h . bimap g i
first (f . g) = first f . first g
second (f . g) = second f . second g
```

bimap : (a -> b) -> (c -> d) -> p a c -> p b d

Map over both arguments at the same time.

```
bimap f g = first f . second g
```

Examples:

```
>>> bimap not (+1) (True, 3)
(False, 4)

>>> bimap not (+1) (Left True)
Left False

>>> bimap not (+1) (Right 3)
Right 4
```

first : (a -> b) -> p a c -> p b c

Map covariantly over the first argument.

```
first f = bimap f identity
```

Examples:

```
>>> first not (True, 3)
(False, 3)

>>> first not (Left True : Either Bool Int)
Left False
```

second : (b -> c) -> p a b -> p a c

Map covariantly over the second argument.

```
second = bimap identity
```

Examples:

```
>>> second (+1) (True, 3)
(True, 4)

>>> second (+1) (Right 3 : Either Bool Int)
Right 4
```

instance *Bifunctor* *Either*

instance *Bifunctor* ()

instance *Bifunctor* x1

instance *Bifunctor* (x1, x2)

instance *Bifunctor* (x1, x2, x3)

instance *Bifunctor* (x1, x2, x3, x4)

instance *Bifunctor* (x1, x2, x3, x4, x5)

45.3.7 DA.BigNumeric

This module exposes operations for working with the `BigNumeric` type.

45.3.7.1 Functions

scale : *BigNumeric* -> *Int*

Calculate the scale of a `BigNumeric` number. The `BigNumeric` number is represented as $n * 10^{-s}$ where n is an integer with no trailing zeros, and s is the scale.

Thus, the scale represents the number of nonzero digits after the decimal point. Note that the scale can be negative if the `BigNumeric` represents an integer with trailing zeros. In that case, it represents the number of trailing zeros (negated).

The scale ranges between 2^{15} and $-2^{15} + 1$. The scale of 0 is 0 by convention.

```
>>> scale 1.1
1
```

```
>>> scale (shiftLeft (2^14) 1.0)
-2^14
```

precision : *BigNumeric* -> *Int*

Calculate the precision of a *BigNumeric* number. The *BigNumeric* number is represented as $n * 10^{-s}$ where n is an integer with no trailing zeros, and s is the scale. The precision is the number of digits in n .

Thus, the precision represents the number of significant digits in the *BigNumeric*.
The precision ranges between 0 and $2^{16} - 1$.

```
>>> precision 1.10
2
```

div : *Int* -> *RoundingMode* -> *BigNumeric* -> *BigNumeric* -> *BigNumeric*

Calculate a division of *BigNumeric* numbers. The value of `div n r a b` is the division of a by b , rounded to n decimal places (i.e. scale), according to the rounding mode r .

This will fail when dividing by 0, and when using the *RoundingUnnecessary* mode for a number that cannot be represented exactly with at most n decimal places.

round : *Int* -> *RoundingMode* -> *BigNumeric* -> *BigNumeric*

Round a *BigNumeric* number. The value of `round n r a` is the value of a rounded to n decimal places (i.e. scale), according to the rounding mode r .

This will fail when using the *RoundingUnnecessary* mode for a number that cannot be represented exactly with at most n decimal places.

shiftRight : *Int* -> *BigNumeric* -> *BigNumeric*

Shift a *BigNumeric* number to the right by a power of 10. The value `shiftRight n a` is the value of a times 10^{-n} .

This will fail if the resulting *BigNumeric* is out of bounds.

```
>>> shiftRight 2 32.0
0.32
```

shiftLeft : *Int* -> *BigNumeric* -> *BigNumeric*

Shift a *BigNumeric* number to the left by a power of 10. The value `shiftLeft n a` is the value of a times 10^n .

This will fail if the resulting *BigNumeric* is out of bounds.

```
>>> shiftLeft 2 32.0
3200.0
```

roundToNumeric : *NumericScale* n => *RoundingMode* -> *BigNumeric* -> *Numeric* n

Round a *BigNumeric* and cast it to a *Numeric*. This function uses the scale of the resulting numeric to determine the scale of the rounding.

This will fail when using the *RoundingUnnecessary* mode if the *BigNumeric* cannot be represented exactly in the requested *Numeric* n .

```
>>> (roundToNumeric RoundingHalfUp 1.23456789 : Numeric 5)
1.23457
```

45.3.8 DA.Date

45.3.8.1 Data Types

data *DayOfWeek*

Monday

Tuesday

Wednesday

Thursday

Friday

Saturday

Sunday

instance *Eq DayOfWeek*

instance *Ord DayOfWeek*

instance *Bounded DayOfWeek*

instance *Enum DayOfWeek*

instance *Show DayOfWeek*

data *Month*

The *Month* type represents a month in the Gregorian calendar.

Note that, while *Month* has an *Enum* instance, the *toEnum* and *fromEnum* functions start counting at 0, i.e. *toEnum 1 :: Month* is *Feb*.

instance *Eq Month*

instance *Ord Month*

instance *Bounded Month*

instance *Enum Month*

instance *Show Month*

45.3.8.2 Functions

addDays : *Date* -> *Int* -> *Date*

Add the given number of days to a date.

subtractDays : *Date* -> *Int* -> *Date*

Subtract the given number of days from a date.

`subtractDays d r` is equivalent to `addDays d (- r)`.

subDate : *Date* -> *Date* -> *Int*

Returns the number of days between the two given dates.

dayOfWeek : *Date* -> *DayOfWeek*

Returns the day of week for the given date.

fromGregorian : (*Int*, *Month*, *Int*) -> *Date*

Constructs a *Date* from the triplet (*year*, *month*, *days*).

toGregorian : *Date* -> (*Int*, *Month*, *Int*)

Turn *Date* value into a (*year*, *month*, *day*) triple, according to the Gregorian calendar.

date : *Int* -> *Month* -> *Int* -> *Date*

Given the three values (*year*, *month*, *day*), constructs a *Date* value. `date y m d` turns the year *y*, month *m*, and day *d* into a *Date* value. Raises an error if *d* is outside the range `1 .. monthDayCount y m`.

isLeapYear : *Int* -> *Bool*

Returns `True` if the given year is a leap year.

fromMonth : *Month* -> *Int*

Get the number corresponding to given month. For example, `Jan` corresponds to 1, `Feb` corresponds to 2, and so on.

monthDayCount : *Int* -> *Month* -> *Int*

Get number of days in the given month in the given year, according to Gregorian calendar. This does not take historical calendar changes into account (for example, the moves from Julian to Gregorian calendar), but does count leap years.

datetime : *Int* -> *Month* -> *Int* -> *Int* -> *Int* -> *Int* -> *Time*

Constructs an instant using *year*, *month*, *day*, *hours*, *minutes*, *seconds*.

toDateUTC : *Time* -> *Date*

Extracts UTC date from UTC time.

This function will truncate *Time* to *Date*, but in many cases it will not return the date you really want. The reason for this is that usually the source of *Time* would be `getTime`, and `getTime` returns UTC, and most likely the date you want is something local to a location or an exchange. Consequently the date retrieved this way would be yesterday if retrieved when the market opens in say Singapore.

passToDate : *Date* -> *Scenario Time*

Within a *scenario*, pass the simulated scenario to given date.

45.3.9 DA.Either

The `Either` type represents values with two possibilities.

It is sometimes used to represent a value which is either correct or an error. By convention, the `Left` constructor is used to hold an error value and the `Right` constructor is used to hold a correct value (mnemonic: "right" also means correct).

45.3.9.1 Functions

`lefts` : `[Either a b] -> [a]`

Extracts all the `Left` elements from a list.

`rights` : `[Either a b] -> [b]`

Extracts all the `Right` elements from a list.

`partitionEithers` : `[Either a b] -> ([a], [b])`

Partitions a list of `Either` into two lists, the `Left` and `Right` elements respectively. Order is maintained.

`isLeft` : `Either a b -> Bool`

Return `True` if the given value is a `Left`-value, `False` otherwise.

`isRight` : `Either a b -> Bool`

Return `True` if the given value is a `Right`-value, `False` otherwise.

`fromLeft` : `a -> Either a b -> a`

Return the contents of a `Left`-value, or a default value in case of a `Right`-value.

`fromRight` : `b -> Either a b -> b`

Return the contents of a `Right`-value, or a default value in case of a `Left`-value.

`optionalToEither` : `a -> Optional b -> Either a b`

Convert a `Optional` value to an `Either` value, using the supplied parameter as the `Left` value if the `Optional` is `None`.

`eitherToOptional` : `Either a b -> Optional b`

Convert an `Either` value to a `Optional`, dropping any value in `Left`.

`maybeToEither` : `a -> Optional b -> Either a b`

`eitherToMaybe` : `Either a b -> Optional b`

45.3.10 DA.Exception

Exception handling in Daml.

45.3.10.1 Typeclasses

class *HasThrow* **e where**

Part of the `Exception` constraint.

throwPure : `e -> t`

Throw exception in a pure context.

instance *HasThrow* *ArithmeticError*

instance *HasThrow* *AssertionFailed*

instance *HasThrow* *GeneralError*

instance *HasThrow* *PreconditionFailed*

class *HasMessage* **e where**

Part of the `Exception` constraint.

message : `e -> Text`

Get the error message associated with an exception.

instance *HasMessage* *AnyException*

instance *HasMessage* *ArithmeticError*

instance *HasMessage* *AssertionFailed*

instance *HasMessage* *GeneralError*

instance *HasMessage* *PreconditionFailed*

class *HasToAnyException* **e where**

Part of the `Exception` constraint.

toAnyException : `e -> AnyException`

Convert an exception type to `AnyException`.

instance *HasToAnyException* *AnyException*

instance *HasToAnyException* *ArithmeticError*

instance *HasToAnyException* *AssertionFailed*

instance *HasToAnyException* *GeneralError*

instance *HasToAnyException* *PreconditionFailed*

class *HasFromAnyException* **e where**

Part of the `Exception` constraint.

fromAnyException : `AnyException -> Optional e`

Convert an `AnyException` back to the underlying exception type, if possible.

instance *HasFromAnyException* *AnyException*

instance *HasFromAnyException* *ArithmeticError*

instance *HasFromAnyException* *AssertionFailed*

instance *HasFromAnyException* *GeneralError*

instance *HasFromAnyException PreconditionFailed*

class *Action* *m => ActionThrow m where*

Action type in which `throw` is supported.

throw : *Exception e => e -> m t*

instance *ActionThrow Scenario*

instance *ActionThrow Update*

class *ActionThrow* *m => ActionCatch m where*

Action type in which `try ... catch ...` is supported.

_tryCatch : *((() -> m t) -> (AnyException -> Optional (m t)) -> m t*

Handle an exception. Use the `try ... catch ...` syntax instead of calling this method directly.

instance *ActionCatch Update*

45.3.10.2 Data Types

type *Exception e = (HasThrow e, HasMessage e, HasToAnyException e, HasFromAnyException e)*

Exception typeclass. This should not be implemented directly, instead, use the `exception` syntax.

data *ArithmeticError*

Exception raised by an arithmetic operation, such as divide-by-zero or overflow.

ArithmeticError

Field	Type	Description
message	<i>Text</i>	

data *AssertionFailed*

Exception raised by `assert` functions in `DA.Assert`

AssertionFailed

Field	Type	Description
message	<i>Text</i>	

data *GeneralError*

Exception raised by `error`.

GeneralError

Field	Type	Description
message	<i>Text</i>	

data *PreconditionFailed*

Exception raised when a contract is invalid, i.e. fails the ensure clause.

PreconditionFailed

Field	Type	Description
message	<i>Text</i>	

45.3.11 DA.Foldable

Class of data structures that can be folded to a summary value. It's a good idea to import this module qualified to avoid clashes with functions defined in `Prelude`. I.e.:

```
import DA.Foldable qualified as F
```

45.3.11.1 Typeclasses

class *Foldable* *t* **where**

Class of data structures that can be folded to a summary value.

fold : *Monoid* *m* => *t m* -> *m*

Combine the elements of a structure using a monoid.

foldMap : *Monoid* *m* => (*a* -> *m*) -> *t a* -> *m*

Combine the elements of a structure using a monoid.

foldr : (*a* -> *b* -> *b*) -> *b* -> *t a* -> *b*

Right-associative fold of a structure.

foldl : (*b* -> *a* -> *b*) -> *b* -> *t a* -> *b*

Left-associative fold of a structure.

foldr1 : (*a* -> *a* -> *a*) -> *t a* -> *a*

A variant of *foldr* that has no base case, and thus should only be applied to non-empty structures.

foldl1 : (*a* -> *a* -> *a*) -> *t a* -> *a*

A variant of *foldl* that has no base case, and thus should only be applied to non-empty structures.

toList : *t a* -> [*a*]

List of elements of a structure, from left to right.

null : *t a* -> *Bool*

Test whether the structure is empty. The default implementation is optimized for structures that are similar to cons-lists, because there is no general way to do better.

length : *t a* -> *Int*

Returns the size/length of a finite structure as an `Int`. The default implementation is optimized for structures that are similar to cons-lists, because there is no general way to do better.

elem : *Eq* a => a -> t a -> *Bool*

Does the element occur in the structure?

sum : *Additive* a => t a -> a

The sum function computes the sum of the numbers of a structure.

product : *Multiplicative* a => t a -> a

The product function computes the product of the numbers of a structure.

minimum : *Ord* a => t a -> a

The least element of a non-empty structure.

maximum : *Ord* a => t a -> a

The largest element of a non-empty structure.

instance *Ord* k => *Foldable* (*Map* k)

instance *Foldable* *TextMap*

instance *Foldable* *Optional*

instance *Foldable* *NonEmpty*

instance *Foldable* *Set*

instance *Foldable* (*Validation* err)

instance *Foldable* (*Either* a)

instance *Foldable* (*[]*)

instance *Foldable* a

45.3.11.2 Functions

mapA_ : (*Foldable* t, *Applicative* f) => (a -> f b) -> t a -> f ()

Map each element of a structure to an action, evaluate these actions from left to right, and ignore the results. For a version that doesn't ignore the results see 'DA.Traversable.mapA'.

forA_ : (*Foldable* t, *Applicative* f) => t a -> (a -> f b) -> f ()

'for_' is 'mapA_' with its arguments flipped. For a version that doesn't ignore the results see 'DA.Traversable.forA'.

forM_ : (*Foldable* t, *Applicative* f) => t a -> (a -> f b) -> f ()

sequence_ : (*Foldable* t, *Action* m) => t (m a) -> m ()

Evaluate each action in the structure from left to right, and ignore the results. For a version that doesn't ignore the results see 'DA.Traversable.sequence'.

concat : *Foldable* t => t [a] -> [a]

The concatenation of all the elements of a container of lists.

and : *Foldable* t => t *Bool* -> *Bool*

and returns the conjunction of a container of Booleans. For the result to be *True*, the container must be finite; *False*, however, results from a *False* value finitely far from the left end.

or : *Foldable* t => t *Bool* -> *Bool*

or returns the disjunction of a container of Booleans. For the result to be *False*, the container must be finite; *True*, however, results from a *True* value finitely far from the left end.

any : *Foldable* t => (a -> *Bool*) -> t a -> *Bool*

Determines whether any element of the structure satisfies the predicate.

all : *Foldable* t => (a -> *Bool*) -> t a -> *Bool*

Determines whether all elements of the structure satisfy the predicate.

45.3.12 DA.Functor

The `Functor` class is used for types that can be mapped over.

45.3.12.1 Functions

(<\$>) : *Functor* f => f a -> b -> f b

Replace all locations in the input (on the left) with the given value (on the right).

(<&>) : *Functor* f => f a -> (a -> b) -> f b

Map a function over a functor. Given a value `as` and a function `f`, `as <&> f` is `f <$> as`. That is, `<&>` is like `<$>` but the arguments are in reverse order.

void : *Functor* f => f a -> f ()

Replace all the locations in the input with `()`.

45.3.13 DA.Internal.Interface.AnyView

45.3.13.1 Typeclasses

class *HasFromAnyView* i v **where**

45.3.13.2 Functions

fromAnyView : (*HasTemplateTypeRep* i, *HasFromAnyView* i v) => *AnyView* -> *Optional* v

45.3.14 DA.Internal.Interface.AnyView.Types

45.3.14.1 Data Types

data *AnyView*

Existential contract key type that can wrap an arbitrary contract key.

AnyView

Field	Type	Description
<code>getAnyView</code>	<code>Any</code>	
<code>getAnyViewInterfaceTypeRep</code>	<i>InterfaceTypeRep</i>	

data *InterfaceTypeRep*

InterfaceTypeRep

Field	Type	Description
getInterfaceTypeRep	TypeRep	

instance *Eq InterfaceTypeRep*

instance *Ord InterfaceTypeRep*

45.3.15 DA.List

List

45.3.15.1 Functions

sort : *Ord* a => [a] -> [a]

The `sort` function implements a stable sorting algorithm. It is a special case of `sortBy`, which allows the programmer to supply their own comparison function.

Elements are arranged from lowest to highest, keeping duplicates in the order they appeared in the input (a stable sort).

sortBy : (a -> a -> *Ordering*) -> [a] -> [a]

The `sortBy` function is the non-overloaded version of `sort`.

minimumBy : (a -> a -> *Ordering*) -> [a] -> a

`minimumBy f xs` returns the first element `x` of `xs` for which `f x y` is either `LT` or `EQ` for all other `y` in `xs`. `xs` must be non-empty.

maximumBy : (a -> a -> *Ordering*) -> [a] -> a

`maximumBy f xs` returns the first element `x` of `xs` for which `f x y` is either `GT` or `EQ` for all other `y` in `xs`. `xs` must be non-empty.

sortOn : *Ord* k => (a -> k) -> [a] -> [a]

Sort a list by comparing the results of a key function applied to each element. `sortOn f` is equivalent to `sortBy (comparing f)`, but has the performance advantage of only evaluating `f` once for each element in the input list. This is sometimes called the decorate-sort-undecorate paradigm.

Elements are arranged from from lowest to highest, keeping duplicates in the order they appeared in the input.

minimumOn : *Ord* k => (a -> k) -> [a] -> a

`minimumOn f xs` returns the first element `x` of `xs` for which `f x` is smaller than or equal to any other `f y` for `y` in `xs`. `xs` must be non-empty.

maximumOn : *Ord* k => (a -> k) -> [a] -> a

`maximumOn f xs` returns the first element `x` of `xs` for which `f x` is greater than or equal to any other `f y` for `y` in `xs`. `xs` must be non-empty.

mergeBy : (a -> a -> *Ordering*) -> [a] -> [a] -> [a]

Merge two sorted lists using into a single, sorted whole, allowing the programmer to specify the comparison function.

combinePairs : (a -> a -> a) -> [a] -> [a]

Combine elements pairwise by means of a programmer supplied function from two list inputs into a single list.

foldBalanced1 : (a -> a -> a) -> [a] -> a

Fold a non-empty list in a balanced way. Balanced means that each element has approximately the same depth in the operator tree. Approximately the same depth means that the difference between maximum and minimum depth is at most 1. The accumulation operation must be associative and commutative in order to get the same result as `foldl1` or `foldr1`.

group : Eq a => [a] -> [[a]]

The ‘group’ function groups equal elements into sublists such that the concatenation of the result is equal to the argument.

groupBy : (a -> a -> Bool) -> [a] -> [[a]]

The ‘groupBy’ function is the non-overloaded version of ‘group’.

groupOn : Eq k => (a -> k) -> [a] -> [[a]]

Similar to ‘group’, except that the equality is done on an extracted value.

dedup : Ord a => [a] -> [a]

`dedup 1` removes duplicate elements from a list. In particular, it keeps only the first occurrence of each element. It is a special case of `dedupBy`, which allows the programmer to supply their own equality test. `dedup` is called `nub` in Haskell.

dedupBy : (a -> a -> Ordering) -> [a] -> [a]

A version of `dedup` with a custom predicate.

dedupOn : Ord k => (a -> k) -> [a] -> [a]

A version of `dedup` where deduplication is done after applying function. Example use: `dedupOn (.employeeNo) employees`

dedupSort : Ord a => [a] -> [a]

The `dedupSort` function sorts and removes duplicate elements from a list. In particular, it keeps only the first occurrence of each element.

dedupSortBy : (a -> a -> Ordering) -> [a] -> [a]

A version of `dedupSort` with a custom predicate.

unique : Ord a => [a] -> Bool

Returns True if and only if there are no duplicate elements in the given list.

uniqueBy : (a -> a -> Ordering) -> [a] -> Bool

A version of `unique` with a custom predicate.

uniqueOn : Ord k => (a -> k) -> [a] -> Bool

Returns True if and only if there are no duplicate elements in the given list after applying function. Example use: `assert $ uniqueOn (.employeeNo) employees`

replace : Eq a => [a] -> [a] -> [a] -> [a]

Given a list and a replacement list, replaces each occurrence of the search list with the replacement list in the operation list.

dropPrefix : Eq a => [a] -> [a] -> [a]

Drops the given prefix from a list. It returns the original sequence if the sequence doesn’t start with the given prefix.

dropSuffix : Eq a => [a] -> [a] -> [a]

Drops the given suffix from a list. It returns the original sequence if the sequence doesn't end with the given suffix.

stripPrefix : *Eq* a => [a] -> [a] -> *Optional* [a]

The `stripPrefix` function drops the given prefix from a list. It returns `None` if the list did not start with the prefix given, or `Some` the list after the prefix, if it does.

stripSuffix : *Eq* a => [a] -> [a] -> *Optional* [a]

Return the prefix of the second list if its suffix matches the entire first list.

stripInfix : *Eq* a => [a] -> [a] -> *Optional* ([a], [a])

Return the string before and after the search string or `None` if the search string is not found.

```
>>> stripInfix [0,0] [1,0,0,2,0,0,3]
Some ([1], [2,0,0,3])

>>> stripInfix [0,0] [1,2,0,4,5]
None
```

isPrefixOf : *Eq* a => [a] -> [a] -> *Bool*

The `isPrefixOf` function takes two lists and returns `True` if and only if the first is a prefix of the second.

isSuffixOf : *Eq* a => [a] -> [a] -> *Bool*

The `isSuffixOf` function takes two lists and returns `True` if and only if the first list is a suffix of the second.

isInfixOf : *Eq* a => [a] -> [a] -> *Bool*

The `isInfixOf` function takes two lists and returns `True` if and only if the first list is contained anywhere within the second.

mapAccumL : (acc -> x -> (acc, y)) -> acc -> [x] -> (acc, [y])

The `mapAccumL` function combines the behaviours of `map` and `foldl1`; it applies a function to each element of a list, passing an accumulating parameter from left to right, and returning a final value of this accumulator together with the new list.

inits : [a] -> [[a]]

The `inits` function returns all initial segments of the argument, shortest first.

intersperse : a -> [a] -> [a]

The `intersperse` function takes an element and a list and "intersperses" that element between the elements of the list.

intercalate : [a] -> [[a]] -> [a]

`intercalate` inserts the list `xs` in between the lists in `xss` and concatenates the result.

tails : [a] -> [[a]]

The `tails` function returns all final segments of the argument, longest first.

dropWhileEnd : (a -> *Bool*) -> [a] -> [a]

A version of `dropWhile` operating from the end.

takeWhileEnd : (a -> *Bool*) -> [a] -> [a]

A version of `takeWhile` operating from the end.

transpose : [[a]] -> [[a]]

The `transpose` function transposes the rows and columns of its argument.

breakEnd : (a -> *Bool*) -> [a] -> ([a], [a])

Break, but from the end.

breakOn : *Eq* a => [a] -> [a] -> ([a], [a])

Find the first instance of `needle` in `haystack`. The first element of the returned tuple is the prefix of `haystack` before `needle` is matched. The second is the remainder of `haystack`, starting with the match. If you want the remainder without the match, use `stripInfix`.

breakOnEnd : *Eq* a => [a] -> [a] -> ([a], [a])

Similar to `breakOn`, but searches from the end of the string.

The first element of the returned tuple is the prefix of `haystack` up to and including the last match of `needle`. The second is the remainder of `haystack`, following the match.

linesBy : (a -> *Bool*) -> [a] -> [[a]]

A variant of `lines` with a custom test. In particular, if there is a trailing separator it will be discarded.

wordsBy : (a -> *Bool*) -> [a] -> [[a]]

A variant of `words` with a custom test. In particular, adjacent separators are discarded, as are leading or trailing separators.

head : [a] -> a

Extract the first element of a list, which must be non-empty.

tail : [a] -> [a]

Extract the elements after the head of a list, which must be non-empty.

last : [a] -> a

Extract the last element of a list, which must be finite and non-empty.

init : [a] -> [a]

Return all the elements of a list except the last one. The list must be non-empty.

foldl1 : (a -> a -> a) -> [a] -> a

Left associative fold of a list that must be non-empty.

foldr1 : (a -> a -> a) -> [a] -> a

Right associative fold of a list that must be non-empty.

repeatedly : ([a] -> (b, [a])) -> [a] -> [b]

Apply some operation repeatedly, producing an element of output and the remainder of the list.

chunksOf : *Int* -> [a] -> [[a]]

Splits a list into chunks of length `@n@`. `@n@` must be strictly greater than zero. The last chunk will be shorter than `@n@` in case the length of the input is not divisible by `@n@`.

delete : *Eq* a => a -> [a] -> [a]

`delete x` removes the first occurrence of `x` from its list argument. For example,

```
> delete "a" ["b", "a", "n", "a", "n", "a"]
["b", "n", "a", "n", "a"]
```

It is a special case of ‘`deleteBy`’, which allows the programmer to supply their own equality test.

deleteBy : (a -> a -> *Bool*) -> a -> [a] -> [a]

The ‘`deleteBy`’ function behaves like ‘`delete`’, but takes a user-supplied equality predicate.

```
> deleteBy (<=) 4 [1..10]
[1, 2, 3, 5, 6, 7, 8, 9, 10]
```

(\\V) : *Eq* a => [a] -> [a] -> [a]

The `\\` function is list difference (non-associative). In the result of `xs \\ ys`, the first occurrence of each element of `ys` in turn (if any) has been removed from `xs`. Thus

```
(xs ++ ys) \\ xs == ys
```

Note this function is $O(n*m)$ given lists of size n and m .

singleton : a -> [a]

Produce a singleton list.

```
>>> singleton True
[True]
```

(!!) : [a] -> Int -> a

List index (subscript) operator, starting from 0. For example, `xs !! 2` returns the third element in `xs`. Raises an error if the index is not suitable for the given list. The function has complexity $O(n)$ where n is the index given, unlike in languages such as Java where array indexing is $O(1)$.

elemIndex : *Eq* a => a -> [a] -> *Optional Int*

Find index of element in given list. Will return `None` if not found.

findIndex : (a -> *Bool*) -> [a] -> *Optional Int*

Find index, given predicate, of first matching element. Will return `None` if not found.

45.3.16 DA.List.BuiltinOrder

Note: This is only supported in Daml-LF 1.11 or later.

This module provides variants of other standard library functions that are based on the builtin Daml-LF ordering rather than user-defined ordering. This is the same order also used by `DA.Map`.

These functions are usually much more efficient than their `Ord`-based counterparts.

Note that the functions in this module still require `Ord` constraints. This is purely to enforce that you don't pass in values that cannot be compared, e.g., functions. The implementation of those instances is not used.

45.3.16.1 Functions

dedup : *Ord* a => [a] -> [a]

`dedup` removes duplicate elements from a list. In particular, it keeps only the first occurrence of each element.

`dedup` is stable so the elements in the output are ordered by their first occurrence in the input. If you do not need stability, consider using `dedupSort` which is more efficient.

```
>>> dedup [3, 1, 1, 3]
[3, 1]
```

dedupOn : *Ord* k => (v -> k) -> [v] -> [v]

A version of `dedup` where deduplication is done after applying the given function. Example use: `dedupOn (.employeeNo) employees`.

`dedupOn` is stable so the elements in the output are ordered by their first occurrence in the input. If you do not need stability, consider using `dedupOnSort` which is more efficient.

```
>>> dedupOn fst [(3, "a"), (1, "b"), (1, "c"), (3, "d")]
[(3, "a"), (1, "b")]
```

dedupSort : *Ord* a => [a] -> [a]

`dedupSort` is a more efficient variant of `dedup` that does not preserve the order of the input elements. Instead the output will be sorted according to the builtin Daml-LF ordering.

```
>>> dedupSort [3, 1, 1, 3]
[1, 3]
```

dedupOnSort : *Ord* k => (v -> k) -> [v] -> [v]

`dedupOnSort` is a more efficient variant of `dedupOn` that does not preserve the order of the input elements. Instead the output will be sorted on the values returned by the function. For duplicates, the first element in the list will be included in the output.

```
>>> dedupOnSort fst [(3, "a"), (1, "b"), (1, "c"), (3, "d")]
[(1, "b"), (3, "a")]
```

sort : *Ord* a => [a] -> [a]

Sort the list according to the Daml-LF ordering.

Values that are identical according to the builtin Daml-LF ordering are indistinguishable so stability is not relevant here.

```
>>> sort [3,1,2]
[1,2,3]
```

sortOn : *Ord* b => (a -> b) -> [a] -> [a]

`sortOn f` is a version of `sort` that allows sorting on the result of the given function.

`sortOn` is stable so elements that map to the same sort key will be ordered by their position in the input.

```
>>> sortOn fst [(3, "a"), (1, "b"), (3, "c"), (2, "d")]
[(1, "b"), (2, "d"), (3, "a"), (3, "c")]
```

unique : *Ord* a => [a] -> *Bool*

Returns True if and only if there are no duplicate elements in the given list.

```
>>> unique [1, 2, 3]
True
```

uniqueOn : *Ord* k => (a -> k) -> [a] -> *Bool*

Returns True if and only if there are no duplicate elements in the given list after applying function.

```
>>> uniqueOn fst [(1, 2), (2, 42), (1, 3)]
False
```

45.3.17 DA.List.Total

45.3.17.1 Functions

head : [a] -> *Optional* a

Return the first element of a list. Return *None* if list is empty.

tail : [a] -> *Optional* [a]

Return all but the first element of a list. Return *None* if list is empty.

last : [a] -> *Optional* a

Extract the last element of a list. Returns *None* if list is empty.

init : [a] -> *Optional* [a]

Return all the elements of a list except the last one. Returns *None* if list is empty.

(!!) : [a] -> *Int* -> *Optional* a

Return the nth element of a list. Return *None* if index is out of bounds.

foldl1 : (a -> a -> a) -> [a] -> *Optional* a

Fold left starting with the head of the list. For example, `foldl1 f [a,b,c] = f (f a b) c`. Return *None* if list is empty.

foldr1 : (a -> a -> a) -> [a] -> *Optional* a

Fold right starting with the last element of the list. For example, `foldr1 f [a,b,c] = f a (f b c)`

foldBalanced1 : (a -> a -> a) -> [a] -> *Optional* a

Fold a non-empty list in a balanced way. Balanced means that each element has approximately the same depth in the operator tree. Approximately the same depth means that the difference between maximum and minimum depth is at most 1. The accumulation operation must be associative and commutative in order to get the same result as `foldl1` or `foldr1`.

Return *None* if list is empty.

minimumBy : (a -> a -> *Ordering*) -> [a] -> *Optional* a

Return the least element of a list according to the given comparison function. Return *None* if list is empty.

maximumBy : (a -> a -> *Ordering*) -> [a] -> *Optional* a

Return the greatest element of a list according to the given comparison function. Return *None* if list is empty.

minimumOn : *Ord* k => (a -> k) -> [a] -> *Optional* a

Return the least element of a list when comparing by a key function. For example `minimumOn (\(x,y) -> x + y) [(1,2), (2,0)] == Some (2,0)`. Return *None* if list is empty.

maximumOn : *Ord* k => (a -> k) -> [a] -> *Optional* a

Return the greatest element of a list when comparing by a key function. For example `maximumOn (\(x,y) -> x + y) [(1,2), (2,0)] == Some (1,2)`. Return *None* if list is empty.

45.3.18 DA.Logic

Logic - Propositional calculus.

45.3.18.1 Data Types

data *Formula* t

A *Formula* t is a formula in propositional calculus with propositions of type t.

Proposition t

Proposition p is the formula p

Negation (*Formula* t)

For a formula f, *Negation* f is $\neg f$

Conjunction [*Formula* t]

For formulas f1, ..., fn, *Conjunction* [f1, ..., fn] is $f_1 \wedge \dots \wedge f_n$

Disjunction [*Formula* t]

For formulas f1, ..., fn, *Disjunction* [f1, ..., fn] is $f_1 \vee \dots \vee f_n$

instance *Action Formula*

instance *Applicative Formula*

instance *Functor Formula*

instance *Eq* t => *Eq* (*Formula* t)

instance *Ord* t => *Ord* (*Formula* t)

instance *Show* t => *Show* (*Formula* t)

45.3.18.2 Functions

(&&&) : *Formula* t -> *Formula* t -> *Formula* t

&&& is the \wedge operation of the boolean algebra of formulas, to be read as "and"

(|||) : *Formula* t -> *Formula* t -> *Formula* t

||| is the \vee operation of the boolean algebra of formulas, to be read as "or"

true : *Formula* t

true is the 1 element of the boolean algebra of formulas, represented as an empty conjunction.

false : *Formula* t

false is the 0 element of the boolean algebra of formulas, represented as an empty disjunction.

neg : *Formula* t -> *Formula* t

neg is the \neg (negation) operation of the boolean algebra of formulas.

conj : [*Formula* t] -> *Formula* t

conj is a list version of &&&, enabled by the associativity of \wedge .

disj : *[Formula t] -> Formula t*

disj is a list version of `|||`, enabled by the associativity of `.`

fromBool : *Bool -> Formula t*

fromBool converts `True` to `true` and `False` to `false`.

toNNF : *Formula t -> Formula t*

toNNF transforms a formula to negation normal form (see https://en.wikipedia.org/wiki/Negation_normal_form).

toDNF : *Formula t -> Formula t*

toDNF turns a formula into disjunctive normal form. (see https://en.wikipedia.org/wiki/Disjunctive_normal_form).

traverse : *Applicative f => (t -> f s) -> Formula t -> f (Formula s)*

An implementation of `traverse` in the usual sense.

zipFormulas : *Formula t -> Formula s -> Formula (t, s)*

zipFormulas takes to formulas of same shape, meaning only propositions are different and zips them up.

substitute : *(t -> Optional Bool) -> Formula t -> Formula t*

substitute takes a truth assignment and substitutes `True` or `False` into the respective places in a formula.

reduce : *Formula t -> Formula t*

reduce reduces a formula as far as possible by:

1. Removing any occurrences of `true` and `false`;
2. Removing directly nested Conjunctions and Disjunctions;
3. Going to negation normal form.

isBool : *Formula t -> Optional Bool*

isBool attempts to convert a formula to a bool. It satisfies `isBool true == Some True` and `isBool false == Some False`. Otherwise, it returns `None`.

interpret : *(t -> Optional Bool) -> Formula t -> Either (Formula t) Bool*

interpret is a version of `toBool` that first substitutes using a truth function and then reduces as far as possible.

substituteA : *Applicative f => (t -> f (Optional Bool)) -> Formula t -> f (Formula t)*

substituteA is a version of `substitute` that allows for truth values to be obtained from an action.

interpretA : *Applicative f => (t -> f (Optional Bool)) -> Formula t -> f (Either (Formula t) Bool)*

interpretA is a version of `interpret` that allows for truth values to be obtained from an action.

45.3.19 DA.Map

Note: This is only supported in Daml-LF 1.11 or later.

This module exports the generic map type `Map k v` and associated functions. This module should be imported qualified, for example:

```
import DA.Map (Map)
import DA.Map qualified as M
```

This will give access to the `Map` type, and the various operations as `M.lookup`, `M.insert`, `M.fromList`, etc.

`Map k v` internally uses the built-in order for the type `k`. This means that keys that contain functions are not comparable and will result in runtime errors. To prevent this, the `Ord k` instance is required for most map operations. It is recommended to only use `Map k v` for key types that have an `Ord k` instance that is derived automatically using `deriving`:

```
data K = ...
  deriving (Eq, Ord)
```

This includes all built-in types that aren't function types, such as `Int`, `Text`, `Bool`, `(a, b)` assuming `a` and `b` have default `Ord` instances, `Optional t` and `[t]` assuming `t` has a default `Ord` instance, `Map k v` assuming `k` and `v` have default `Ord` instances, and `Set k` assuming `k` has a default `Ord` instance.

45.3.19.1 Functions

`fromList` : `Ord k => [(k, v)] -> Map k v`

Create a map from a list of key/value pairs.

`fromListWithL` : `Ord k => (v -> v -> v) -> [(k, v)] -> Map k v`

Create a map from a list of key/value pairs with a combining function. The combining function is only used when a key appears multiple times in the list and it takes two arguments: the first one is the new value being inserted at that key and the second one is the value accumulated so far at that key. Examples:

```
>>> fromListWithL (++) [("A", [1]), ("A", [2]), ("B", [2]), ("B", [1]), ("A", [3])]
↳ [3]]
fromList [("A", [3, 2, 1]), ("B", [1, 2])]
>>> fromListWithL (++) [] == (empty : Map Text [Int])
True
```

`fromListWithR` : `Ord k => (v -> v -> v) -> [(k, v)] -> Map k v`

Create a map from a list of key/value pairs like `fromListWithL` with the combining function flipped. Examples:

```
>>> fromListWithR (++) [("A", [1]), ("A", [2]), ("B", [2]), ("B", [1]), ("A", [3])]
↳ [3]]
fromList [("A", [1, 2, 3]), ("B", [2, 1])]
>>> fromListWithR (++) [] == (empty : Map Text [Int])
True
```

`fromListWith` : `Ord k => (v -> v -> v) -> [(k, v)] -> Map k v`

keys : `Map k v -> [k]`

Get the list of keys in the map. Keys are sorted according to the built-in order for the type `k`, which matches the `Ord k` instance when using `deriving Ord`.

```
>>> keys (fromList [("A", 1), ("C", 3), ("B", 2)])
["A", "B", "C"]
```

values : `Map k v -> [v]`

Get the list of values in the map. These will be in the same order as their respective keys from `M.keys`.

```
>>> values (fromList [("A", 1), ("B", 2)])
[1, 2]
```

toList : `Map k v -> [(k, v)]`

Convert the map to a list of key/value pairs. These will be ordered by key, as in `M.keys`.

empty : `Map k v`

The empty map.

size : `Map k v -> Int`

Number of elements in the map.

null : `Map k v -> Bool`

Is the map empty?

lookup : `Ord k => k -> Map k v -> Optional v`

Lookup the value at a key in the map.

member : `Ord k => k -> Map k v -> Bool`

Is the key a member of the map?

filter : `Ord k => (v -> Bool) -> Map k v -> Map k v`

Filter the `Map` using a predicate: keep only the entries where the value satisfies the predicate.

filterWithKey : `Ord k => (k -> v -> Bool) -> Map k v -> Map k v`

Filter the `Map` using a predicate: keep only the entries which satisfy the predicate.

delete : `Ord k => k -> Map k v -> Map k v`

Delete a key and its value from the map. When the key is not a member of the map, the original map is returned.

insert : `Ord k => k -> v -> Map k v -> Map k v`

Insert a new key/value pair in the map. If the key is already present in the map, the associated value is replaced with the supplied value.

insertWith : `Ord k => (v -> v -> v) -> k -> v -> Map k v -> Map k v`

Insert a new key/value pair in the map. If the key is already present in the map, it is combined with the previous value using the given function `f new_value old_value`.

alter : `Ord k => (Optional v -> Optional v) -> k -> Map k v -> Map k v`

Update the value in `m` at `k` with `f`, inserting or deleting as required. `f` will be called with either the value at `k`, or `None` if absent; `f` can return `Some` with a new value to be inserted in `m` (replacing the old value if there was one), or `None` to remove any `k` association `m` may have.

Some implications of this behavior:

`alter identity k = identity alter g k`. `alter f k = alter (g . f) k` `alter (λ _ -> Some v) k = insert k v` `alter (λ _ -> None) = delete`

union : *Ord* k => *Map* k v -> *Map* k v -> *Map* k v

The union of two maps, preferring the first map when equal keys are encountered.

unionWith : *Ord* k => (v -> v -> v) -> *Map* k v -> *Map* k v -> *Map* k v

The union of two maps using the combining function to merge values that exist in both maps.

merge : *Ord* k => (k -> a -> *Optional* c) -> (k -> b -> *Optional* c) -> (k -> a -> b -> *Optional* c) -> *Map* k a -> *Map* k b -> *Map* k c

Combine two maps, using separate functions based on whether a key appears only in the first map, only in the second map, or appears in both maps.

45.3.20 DA.Math

Math - Utility Math functions for `Decimal` The this library is designed to give good precision, typically giving 9 correct decimal places. The numerical algorithms run with many iterations to achieve that precision and are interpreted by the Daml runtime so they are not performant. Their use is not advised in performance critical contexts.

45.3.20.1 Functions

()** : *Decimal* -> *Decimal* -> *Decimal*

Take a power of a number Example: `2.0 ** 3.0 == 8.0`.

sqrt : *Decimal* -> *Decimal*

Calculate the square root of a `Decimal`.

```
>>> sqrt 1.44
1.2
```

exp : *Decimal* -> *Decimal*

The exponential function. Example: `exp 0.0 == 1.0`

log : *Decimal* -> *Decimal*

The natural logarithm. Example: `log 10.0 == 2.30258509299`

logBase : *Decimal* -> *Decimal* -> *Decimal*

The logarithm of a number to a given base. Example: `log 10.0 100.0 == 2.0`

sin : *Decimal* -> *Decimal*

`sin` is the sine function

cos : *Decimal* -> *Decimal*

`cos` is the cosine function

tan : *Decimal* -> *Decimal*

`tan` is the tangent function

45.3.21 DA.Monoid

45.3.21.1 Data Types

data *All*

Boolean monoid under conjunction (&&)

All

Field	Type	Description
getAll	<i>Bool</i>	

instance *Monoid All*

instance *Semigroup All*

instance *Eq All*

instance *Ord All*

instance *Show All*

data *Any*

Boolean Monoid under disjunction (||)

Any

Field	Type	Description
getAny	<i>Bool</i>	

instance *Monoid Any*

instance *Semigroup Any*

instance *Eq Any*

instance *Ord Any*

instance *Show Any*

data *Endo* a

The monoid of endomorphisms under composition.

Endo

Field	Type	Description
appEndo	<i>a -> a</i>	

instance *Monoid (Endo a)*

instance *Semigroup (Endo a)*

data *Product* a

Monoid under (*)

```
> Product 2 <> Product 3
Product 6
```

Product a

instance *Multiplicative* a => *Monoid* (*Product* a)

instance *Multiplicative* a => *Semigroup* (*Product* a)

instance *Additive* a => *Additive* (*Sum* a)

instance *Multiplicative* a => *Multiplicative* (*Sum* a)

instance *Show* a => *Show* (*Sum* a)

45.3.22 DA.NonEmpty

Type and functions for non-empty lists. This module re-exports many functions with the same name as prelude list functions, so it is expected to import the module qualified. For example, with the following import list you will have access to the `NonEmpty` type and any functions on non-empty lists will be qualified, for example as `NE.append`, `NE.map`, `NE.foldl`:

```
import DA.NonEmpty (NonEmpty)
import qualified DA.NonEmpty as NE
```

45.3.22.1 Functions

cons : $a \rightarrow \text{NonEmpty } a \rightarrow \text{NonEmpty } a$

Prepend an element to a non-empty list.

append : $\text{NonEmpty } a \rightarrow \text{NonEmpty } a \rightarrow \text{NonEmpty } a$

Append or concatenate two non-empty lists.

map : $(a \rightarrow b) \rightarrow \text{NonEmpty } a \rightarrow \text{NonEmpty } b$

Apply a function over each element in the non-empty list.

nonEmpty : $[a] \rightarrow \text{Optional } (\text{NonEmpty } a)$

Turn a list into a non-empty list, if possible. Returns `None` if the input list is empty, and `Some` otherwise.

singleton : $a \rightarrow \text{NonEmpty } a$

A non-empty list with a single element.

toList : $\text{NonEmpty } a \rightarrow [a]$

Turn a non-empty list into a list (by forgetting that it is not empty).

reverse : $\text{NonEmpty } a \rightarrow \text{NonEmpty } a$

Reverse a non-empty list.

find : $(a \rightarrow \text{Bool}) \rightarrow \text{NonEmpty } a \rightarrow \text{Optional } a$

Find an element in a non-empty list.

deleteBy : $(a \rightarrow a \rightarrow \text{Bool}) \rightarrow a \rightarrow \text{NonEmpty } a \rightarrow [a]$

The ‘deleteBy’ function behaves like ‘delete’, but takes a user-supplied equality predicate.

delete : $\text{Eq } a \Rightarrow a \rightarrow \text{NonEmpty } a \rightarrow [a]$

Remove the first occurrence of `x` from the non-empty list, potentially removing all elements.

foldl1 : $(a \rightarrow a \rightarrow a) \rightarrow \text{NonEmpty } a \rightarrow a$

Apply a function repeatedly to pairs of elements from a non-empty list, from the left. For example, `foldl1 (+) (NonEmpty 1 [2,3,4]) = ((1 + 2) + 3) + 4`.

foldr1 : $(a \rightarrow a \rightarrow a) \rightarrow \text{NonEmpty } a \rightarrow a$

Apply a function repeatedly to pairs of elements from a non-empty list, from the right. For example, `foldr1 (+) (NonEmpty 1 [2,3,4]) = 1 + (2 + (3 + 4))`.

foldr : $(a \rightarrow b \rightarrow b) \rightarrow b \rightarrow \text{NonEmpty } a \rightarrow b$

Apply a function repeatedly to pairs of elements from a non-empty list, from the right, with a given initial value. For example, `foldr (+) 0 (NonEmpty 1 [2,3,4]) = 1 + (2 + (3 + (4 + 0)))`.

foldrA : $\text{Action } m \Rightarrow (a \rightarrow b \rightarrow m b) \rightarrow b \rightarrow \text{NonEmpty } a \rightarrow m b$

The same as `foldr` but running an action each time.

foldr1A : $\text{Action } m \Rightarrow (a \rightarrow a \rightarrow m a) \rightarrow \text{NonEmpty } a \rightarrow m a$

The same as `foldr1` but running an action each time.

foldl : $(b \rightarrow a \rightarrow b) \rightarrow b \rightarrow \text{NonEmpty } a \rightarrow b$

Apply a function repeatedly to pairs of elements from a non-empty list, from the left, with a given initial value. For example, `foldl (+) 0 (NonEmpty 1 [2,3,4]) = (((0 + 1) + 2) + 3) + 4`.

foldlA : $\text{Action } m \Rightarrow (b \rightarrow a \rightarrow m b) \rightarrow b \rightarrow \text{NonEmpty } a \rightarrow m b$

The same as `foldl` but running an action each time.

foldl1A : *Action* m => (a -> a -> m a) -> *NonEmpty* a -> m a
The same as `foldl1` but running an action each time.

45.3.23 DA.NonEmpty.Types

This module contains the type for non-empty lists so we can give it a stable package id. This is reexported from `DA.NonEmpty` so you should never need to import this module.

45.3.23.1 Data Types

data *NonEmpty* a

`NonEmpty` is the type of non-empty lists. In other words, it is the type of lists that always contain at least one element. If `x` is a non-empty list, you can obtain the first element with `x.hd` and the rest of the list with `x.tl`.

NonEmpty

Field	Type	Description
hd	a	
tl	[a]	

instance *Foldable NonEmpty*

instance *Action NonEmpty*

instance *Applicative NonEmpty*

instance *Semigroup* (*NonEmpty* a)

instance *IsParties* (*NonEmpty Party*)

instance *Traversable NonEmpty*

instance *Functor NonEmpty*

instance *Eq* a => *Eq* (*NonEmpty* a)

instance *Ord* a => *Ord* (*NonEmpty* a)

instance *Show* a => *Show* (*NonEmpty* a)

45.3.24 DA.Numeric

45.3.24.1 Functions

mul : *NumericScale* n3 => *Numeric* n1 -> *Numeric* n2 -> *Numeric* n3

Multiply two numerics. Both inputs and the output may have different scales, unlike `(*)` which forces all numeric scales to be the same. Raises an error on overflow, rounds to chosen scale otherwise.

div : *NumericScale* n3 => *Numeric* n1 -> *Numeric* n2 -> *Numeric* n3

Divide two numerics. Both inputs and the output may have different scales, unlike `(/)` which forces all numeric scales to be the same. Raises an error on overflow, rounds to chosen scale otherwise.

cast : *NumericScale* n2 => *Numeric* n1 -> *Numeric* n2

Cast a Numeric. Raises an error on overflow or loss of precision.

castAndRound : *NumericScale* n2 => *Numeric* n1 -> *Numeric* n2

Cast a Numeric. Raises an error on overflow, rounds to chosen scale otherwise.

shift : *NumericScale* n2 => *Numeric* n1 -> *Numeric* n2

Move the decimal point left or right by multiplying the numeric value by $10^{(n1 - n2)}$. Does not overflow or underflow.

pi : *NumericScale* n => *Numeric* n

The number pi.

roundNumeric : *NumericScale* n => *Int* -> *RoundingMode* -> *Numeric* n -> *Numeric* n

Round a Numeric number. The value of `round n r a` is the value of `a` rounded to `n` decimal places (i.e. scale), according to the rounding mode `r`.

This will fail when using the `RoundingUnnecessary` mode for a number that cannot be represented exactly with at most `n` decimal places.

45.3.25 DA.Optional

The `Optional` type encapsulates an optional value. A value of type `Optional a` either contains a value of type `a` (represented as `Some a`), or it is empty (represented as `None`). Using `Optional` is a good way to deal with errors or exceptional cases without resorting to drastic measures such as error.

The `Optional` type is also an action. It is a simple kind of error action, where all errors are represented by `None`. A richer error action can be built using the `Either` type.

45.3.25.1 Functions

fromSome : *Optional* a -> a

The `fromSome` function extracts the element out of a `Some` and throws an error if its argument is `None`.

Note that in most cases you should prefer using `fromSomeNote` to get a better error on failures.

fromSomeNote : *Text* -> *Optional* a -> a

Like `fromSome` but with a custom error message.

catOptionals : [*Optional* a] -> [a]

The `catOptionals` function takes a list of `Optionals` and returns a list of all the `Some` values.

listToOptional : [a] -> *Optional* a

The `listToOptional` function returns `None` on an empty list or `Some a` where `a` is the first element of the list.

optionalToList : *Optional* a -> [a]

The `optionalToList` function returns an empty list when given `None` or a singleton list when not given `None`.

fromOptional : *a* -> *Optional a* -> *a*

The `fromOptional` function takes a default value and a `Optional` value. If the `Optional` is `None`, it returns the default values otherwise, it returns the value contained in the `Optional`.

isSome : *Optional a* -> *Bool*

The `isSome` function returns `True` iff its argument is of the form `Some _`.

isNone : *Optional a* -> *Bool*

The `isNone` function returns `True` iff its argument is `None`.

mapOptional : (*a* -> *Optional b*) -> [*a*] -> [*b*]

The `mapOptional` function is a version of `map` which can throw out elements. In particular, the functional argument returns something of type `Optional b`. If this is `None`, no element is added on to the result list. If it is `Some b`, then `b` is included in the result list.

whenSome : *Applicative m* => *Optional a* -> (*a* -> *m ()*) -> *m ()*

Perform some operation on `Some`, given the field inside the `Some`.

findOptional : (*a* -> *Optional b*) -> [*a*] -> *Optional b*

The `findOptional` returns the value of the predicate at the first element where it returns `Some`. `findOptional` is similar to `find` but it allows you to return a value from the predicate. This is useful both as a more type safe version if the predicate corresponds to a pattern match and for performance to avoid duplicating work performed in the predicate.

45.3.26 DA.Record

Exports the record machinery necessary to allow one to annotate code that is polymorphic in the underlying record type.

45.3.26.1 Typeclasses

class *HasField* *x r a* **where**

`HasField` gives you getter and setter functions for each record field automatically.

In the vast majority of use-cases, plain Record syntax should be preferred:

```
daml> let a = MyRecord 1 "hello"
daml> a.foo
1
daml> a.bar
"hello"
daml> a { bar = "bye" }
MyRecord {foo = 1, bar = "bye"}
daml> a with foo = 3
MyRecord {foo = 3, bar = "hello"}
daml>
```

For more on Record syntax, see https://docs.daml.com/daml/intro/3_Data.html#record.

`HasField x r a` is a typeclass that takes three parameters. The first parameter `x` is the field name, the second parameter `r` is the record type, and the last parameter `a` is the type of the field in this record. For example, if we define a type:

```
data MyRecord = MyRecord with
  foo : Int
  bar : Text
```

Then we get, for free, the following HasField instances:

```
HasField "foo" MyRecord Int
HasField "bar" MyRecord Text
```

If we want to get a value using HasField, we can use the `getField` function:

```
getFoo : MyRecord -> Int
getFoo r = getField @"foo" r

getBar : MyRecord -> Text
getBar r = getField @"bar" r
```

Note that this uses the `type application` syntax (`f @t`) to specify the field name.

Likewise, if we want to set the value in the field, we can use the `setField` function:

```
setFoo : Int -> MyRecord -> MyRecord
setFoo a r = setField @"foo" a r

setBar : Text -> MyRecord -> MyRecord
setBar a r = setField @"bar" a r
```

`getField` : `r -> a`

`setField` : `a -> r -> r`

45.3.27 DA.Semigroup

45.3.27.1 Data Types

data `Max` `a`

Semigroup under `max`

```
> Max 23 <> Max 42
Max 42
```

`Max` `a`

instance `Ord` `a` => `Semigroup` (`Max` `a`)

instance `Eq` `a` => `Eq` (`Max` `a`)

instance `Ord` `a` => `Ord` (`Max` `a`)

instance `Show` `a` => `Show` (`Max` `a`)

data `Min` `a`

Semigroup under `min`

```
> Min 23 <> Min 42
Min 23
```

Min a

instance *Ord* a => *Semigroup* (*Min* a)

instance *Eq* a => *Eq* (*Min* a)

instance *Ord* a => *Ord* (*Min* a)

instance *Show* a => *Show* (*Min* a)

45.3.28 DA.Set

Note: This is only supported in Daml-LF 1.11 or later.

This module exports the generic set type `Set k` and associated functions. This module should be imported qualified, for example:

```
import DA.Set (Set)
import DA.Set qualified as S
```

This will give access to the `Set` type, and the various operations as `S.lookup`, `S.insert`, `S.fromList`, etc.

`Set k` internally uses the built-in order for the type `k`. This means that keys that contain functions are not comparable and will result in runtime errors. To prevent this, the `Ord k` instance is required for most set operations. It is recommended to only use `Set k` for key types that have an `Ord k` instance that is derived automatically using `deriving`:

```
data K = ...
  deriving (Eq, Ord)
```

This includes all built-in types that aren't function types, such as `Int`, `Text`, `Bool`, `(a, b)` assuming `a` and `b` have default `Ord` instances, `Optional t` and `[t]` assuming `t` has a default `Ord` instance, `Map k v` assuming `k` and `v` have default `Ord` instances, and `Set k` assuming `k` has a default `Ord` instance.

45.3.28.1 Data Types

data `Set k`

The type of a set. This is a wrapper over the `Map` type.

`Set`

Field	Type	Description
map	<code>Map k ()</code>	

instance *Foldable* *Set*

instance *Ord* k => *Monoid* (*Set* k)

```

instance Ord k => Semigroup (Set k)
instance IsParties (Set Party)
instance Ord k => Eq (Set k)
instance Ord k => Ord (Set k)
instance (Ord k, Show k) => Show (Set k)

```

45.3.28.2 Functions

```

empty : Set k
  The empty set.

size : Set k -> Int
  The number of elements in the set.

toList : Set k -> [k]
  Convert the set to a list of elements.

fromList : Ord k => [k] -> Set k
  Create a set from a list of elements.

toMap : Set k -> Map k ()
  Convert a Set into a Map.

fromMap : Map k () -> Set k
  Create a Set from a Map.

member : Ord k => k -> Set k -> Bool
  Is the element in the set?

notMember : Ord k => k -> Set k -> Bool
  Is the element not in the set? notMember k s is equivalent to not (member k s).

null : Set k -> Bool
  Is this the empty set?

insert : Ord k => k -> Set k -> Set k
  Insert an element in a set. If the set already contains the element, this returns the set unchanged.

filter : Ord k => (k -> Bool) -> Set k -> Set k
  Filter all elements that satisfy the predicate.

delete : Ord k => k -> Set k -> Set k
  Delete an element from a set.

singleton : Ord k => k -> Set k
  Create a singleton set.

union : Ord k => Set k -> Set k -> Set k
  The union of two sets.

intersection : Ord k => Set k -> Set k -> Set k
  The intersection of two sets.

difference : Ord k => Set k -> Set k -> Set k
  difference x y returns the set consisting of all elements in x that are not in y.

```

>>> fromList [1, 2, 3] difference fromList [1, 4] >>> fromList [2, 3]

isSubsetOf : Ord k => Set k -> Set k -> Bool

isSubsetOf a b returns true if a is a subset of b, that is, if every element of a is in b.

isProperSubsetOf : Ord k => Set k -> Set k -> Bool

isProperSubsetOf a b returns true if a is a proper subset of b. That is, if a is a subset of b but not equal to b.

45.3.29 DA.Stack

45.3.29.1 Data Types

data SrcLoc

Location in the source code.

Line and column are 0-based.

SrcLoc

Field	Type	Description
srcLocPackage	Text	
srcLocModule	Text	
srcLocFile	Text	
srcLocStartLine	Int	
srcLocStartCol	Int	
srcLocEndLine	Int	
srcLocEndCol	Int	

data CallStack

Type of callstacks constructed automatically from HasCallStack constraints.

Use callStack to get the current callstack, and use getCallStack to deconstruct the CallStack.

type HasCallStack = IP "callStack" CallStack

Request a CallStack. Use this as a constraint in type signatures in order to get nicer callstacks for error and debug messages.

For example, instead of declaring the following type signature:

```
myFunction : Int -> Update ()
```

You can declare a type signature with the HasCallStack constraint:

```
myFunction : HasCallStack => Int -> Update ()
```

The function myFunction will still be called the same way, but it will also show up as an entry in the current callstack, which you can obtain with callStack.

Note that only functions with the HasCallStack constraint will be added to the current callstack, and if any function does not have the HasCallStack constraint, the callstack will be reset within that function.

45.3.29.2 Functions

prettyCallStack : *CallStack* -> *Text*

Pretty-print a *CallStack*.

getCallStack : *CallStack* -> [(*Text*, *SrcLoc*)]

Extract the list of call sites from the *CallStack*.

The most recent call comes first.

callStack : *HasCallStack* => *CallStack*

Access to the current *CallStack*.

45.3.30 DA.Text

Functions for working with *Text*.

45.3.30.1 Functions

explode : *Text* -> [*Text*]

implode : [*Text*] -> *Text*

isEmpty : *Text* -> *Bool*

Test for emptiness.

length : *Text* -> *Int*

Compute the number of symbols in the text.

trim : *Text* -> *Text*

Remove spaces from either side of the given text.

replace : *Text* -> *Text* -> *Text* -> *Text*

Replace a subsequence everywhere it occurs. The first argument must not be empty.

lines : *Text* -> [*Text*]

Breaks a *Text* value up into a list of *Text*'s at newline symbols. The resulting texts do not contain newline symbols.

unlines : [*Text*] -> *Text*

Joins lines, after appending a terminating newline to each.

words : *Text* -> [*Text*]

Breaks a 'Text' up into a list of words, delimited by symbols representing white space.

unwords : [*Text*] -> *Text*

Joins words using single space symbols.

linesBy : (*Text* -> *Bool*) -> *Text* -> [*Text*]

A variant of *lines* with a custom test. In particular, if there is a trailing separator it will be discarded.

wordsBy : (*Text* -> *Bool*) -> *Text* -> [*Text*]

A variant of *words* with a custom test. In particular, adjacent separators are discarded, as are leading or trailing separators.

intercalate : `Text -> [Text] -> Text`

`intercalate` inserts the text argument `t` in between the items in `ts` and concatenates the result.

dropPrefix : `Text -> Text -> Text`

`dropPrefix` drops the given prefix from the argument. It returns the original text if the text doesn't start with the given prefix.

dropSuffix : `Text -> Text -> Text`

Drops the given suffix from the argument. It returns the original text if the text doesn't end with the given suffix. Examples:

```
dropSuffix "!" "Hello World!" == "Hello World"
dropSuffix "!" "Hello World!!" == "Hello World!"
dropSuffix "!" "Hello World." == "Hello World."
```

stripSuffix : `Text -> Text -> Optional Text`

Return the prefix of the second text if its suffix matches the entire first text. Examples:

```
stripSuffix "bar" "foobar" == Some "foo"
stripSuffix "" "baz" == Some "baz"
stripSuffix "foo" "quux" == None
```

stripPrefix : `Text -> Text -> Optional Text`

The `stripPrefix` function drops the given prefix from the argument text. It returns `None` if the text did not start with the prefix.

isPrefixOf : `Text -> Text -> Bool`

The `isPrefixOf` function takes two text arguments and returns `True` if and only if the first is a prefix of the second.

isSuffixOf : `Text -> Text -> Bool`

The `isSuffixOf` function takes two text arguments and returns `True` if and only if the first is a suffix of the second.

isInfixOf : `Text -> Text -> Bool`

The `isInfixOf` function takes two text arguments and returns `True` if and only if the first is contained, wholly and intact, anywhere within the second.

takeWhile : `(Text -> Bool) -> Text -> Text`

The function `takeWhile`, applied to a predicate `p` and a text, returns the longest prefix (possibly empty) of symbols that satisfy `p`.

takeWhileEnd : `(Text -> Bool) -> Text -> Text`

The function 'takeWhileEnd', applied to a predicate `p` and a 'Text', returns the longest suffix (possibly empty) of elements that satisfy `p`.

dropWhile : `(Text -> Bool) -> Text -> Text`

`dropWhile p t` returns the suffix remaining after `takeWhile p t`.

dropWhileEnd : `(Text -> Bool) -> Text -> Text`

`dropWhileEnd p t` returns the prefix remaining after dropping symbols that satisfy the predicate `p` from the end of `t`.

splitOn : `Text -> Text -> [Text]`

Break a text into pieces separated by the first text argument (which cannot be empty), consuming the delimiter.

splitAt : *Int* -> *Text* -> (*Text*, *Text*)

Split a text before a given position so that for $0 \leq n \leq \text{length } t$, $\text{length } (\text{fst } (\text{splitAt } n \ t)) == n$.

take : *Int* -> *Text* -> *Text*

take *n*, applied to a text *t*, returns the prefix of *t* of length *n*, or *t* itself if *n* is greater than the length of *t*.

drop : *Int* -> *Text* -> *Text*

drop *n*, applied to a text *t*, returns the suffix of *t* after the first *n* characters, or the empty *Text* if *n* is greater than the length of *t*.

substring : *Int* -> *Int* -> *Text* -> *Text*

Compute the sequence of symbols of length *l* in the argument text starting at *s*.

isPred : (*Text* -> *Bool*) -> *Text* -> *Bool*

isPred *f t* returns *True* if *t* is not empty and *f* is *True* for all symbols in *t*.

isSpace : *Text* -> *Bool*

isSpace *t* is *True* if *t* is not empty and consists only of spaces.

isNewLine : *Text* -> *Bool*

isSpace *t* is *True* if *t* is not empty and consists only of newlines.

isUpper : *Text* -> *Bool*

isUpper *t* is *True* if *t* is not empty and consists only of uppercase symbols.

isLower : *Text* -> *Bool*

isLower *t* is *True* if *t* is not empty and consists only of lowercase symbols.

isDigit : *Text* -> *Bool*

isDigit *t* is *True* if *t* is not empty and consists only of digit symbols.

isAlpha : *Text* -> *Bool*

isAlpha *t* is *True* if *t* is not empty and consists only of alphabet symbols.

isAlphaNum : *Text* -> *Bool*

isAlphaNum *t* is *True* if *t* is not empty and consists only of alphanumeric symbols.

parseInt : *Text* -> *Optional Int*

Attempt to parse an *Int* value from a given *Text*.

parseNumeric : *NumericScale n* => *Text* -> *Optional (Numeric n)*

Attempt to parse a *Numeric* value from a given *Text*. To get *Some* value, the text must follow the regex $(-|\backslash+)?[0-9]+(\backslash.[0-9]+)?$. In particular, the shorthands *".12"* and *"12."* do not work, but the value can be prefixed with *+*. Leading and trailing zeros are fine, however spaces are not. Examples:

```
parseNumeric "3.14" == Some 3.14
parseNumeric "+12.0" == Some 12
```

parseDecimal : *Text* -> *Optional Decimal*

Attempt to parse a *Decimal* value from a given *Text*. To get *Some* value, the text must follow the regex $(-|\backslash+)?[0-9]+(\backslash.[0-9]+)?$. In particular, the shorthands *".12"* and *"12."* do not work, but the value can be prefixed with *+*. Leading and trailing zeros are fine, however spaces are not. Examples:

```
parseDecimal "3.14" == Some 3.14
parseDecimal "+12.0" == Some 12
```

sha256 : `Text` -> `Text`

Computes the SHA256 hash of the UTF8 bytes of the `Text`, and returns it in its hex-encoded form. The hex encoding uses lowercase letters.

This function will crash at runtime if you compile Daml to Daml-LF < 1.2.

reverse : `Text` -> `Text`

Reverse some `Text`.

```
reverse "Daml" == "lmaD"
```

toCodePoints : `Text` -> `[Int]`

Convert a `Text` into a sequence of unicode code points.

fromCodePoints : `[Int]` -> `Text`

Convert a sequence of unicode code points into a `Text`. Raises an exception if any of the code points is invalid.

asciiToLower : `Text` -> `Text`

Convert the uppercase ASCII characters of a `Text` to lowercase; all other characters remain unchanged.

asciiToUpper : `Text` -> `Text`

Convert the lowercase ASCII characters of a `Text` to uppercase; all other characters remain unchanged.

45.3.31 DA.TextMap

TextMap - A map is an associative array data type composed of a collection of key/value pairs such that, each possible key appears at most once in the collection.

45.3.31.1 Functions

fromList : `[(Text, a)]` -> `TextMap a`

Create a map from a list of key/value pairs.

fromListWithL : `(a -> a -> a) -> [(Text, a)] -> TextMap a`

Create a map from a list of key/value pairs with a combining function. The combining function is only used when a key appears multiple times in the list and it takes two arguments: the first one is the new value being inserted at that key and the second one is the value accumulated so far at that key. Examples:

```
>>> fromListWithL (++) [("A", [1]), ("A", [2]), ("B", [2]), ("B", [1]), ("A", [3])]
↪ [3])
fromList [("A", [3, 2, 1]), ("B", [1, 2])]
>>> fromListWithL (++) [] == (empty : TextMap [Int])
True
```

fromListWithR : `(a -> a -> a) -> [(Text, a)] -> TextMap a`

Create a map from a list of key/value pairs like `fromListWithL` with the combining function flipped. Examples:

```
>>> fromListWithR (++) [("A", [1]), ("A", [2]), ("B", [2]), ("B", [1]), ("A", [3])]
↪[3]])
fromList [("A", [1, 2, 3]), ("B", [2, 1])]
>>> fromListWithR (++) [] == (empty : TextMap [Int])
True
```

fromListWith : (a -> a -> a) -> [(Text, a)] -> TextMap a

toList : TextMap a -> [(Text, a)]

Convert the map to a list of key/value pairs where the keys are in ascending order.

empty : TextMap a

The empty map.

size : TextMap a -> Int

Number of elements in the map.

null : TextMap v -> Bool

Is the map empty?

lookup : Text -> TextMap a -> Optional a

Lookup the value at a key in the map.

member : Text -> TextMap v -> Bool

Is the key a member of the map?

filter : (v -> Bool) -> TextMap v -> TextMap v

Filter the TextMap using a predicate: keep only the entries where the value satisfies the predicate.

filterWithKey : (Text -> v -> Bool) -> TextMap v -> TextMap v

Filter the TextMap using a predicate: keep only the entries which satisfy the predicate.

delete : Text -> TextMap a -> TextMap a

Delete a key and its value from the map. When the key is not a member of the map, the original map is returned.

insert : Text -> a -> TextMap a -> TextMap a

Insert a new key/value pair in the map. If the key is already present in the map, the associated value is replaced with the supplied value.

insertWith : (v -> v -> v) -> Text -> v -> TextMap v -> TextMap v

Insert a new key/value pair in the map. If the key is already present in the map, it is combined with the previous value using the given function `f new_value old_value`.

union : TextMap a -> TextMap a -> TextMap a

The union of two maps, preferring the first map when equal keys are encountered.

merge : (Text -> a -> Optional c) -> (Text -> b -> Optional c) -> (Text -> a -> b -> Optional c) -> TextMap a -> TextMap b -> TextMap c

Merge two maps. `merge f g h x y` applies `f` to all key/value pairs whose key only appears in `x`, `g` to all pairs whose key only appears in `y` and `h` to all pairs whose key appears in both `x` and `y`. In the end, all pairs yielding `Some` are collected as the result.

45.3.32 DA.Time

45.3.32.1 Data Types

data *RelTime*

The *RelTime* type describes a time offset, i.e. relative time.

instance *Eq RelTime*

instance *Ord RelTime*

instance *Additive RelTime*

instance *Signed RelTime*

instance *Show RelTime*

45.3.32.2 Functions

time : *Date* -> *Int* -> *Int* -> *Int* -> *Time*

time *d h m s* turns given UTC date *d* and the UTC time (given in hours, minutes, seconds) into a UTC timestamp (*Time*). Does not handle leap seconds.

pass : *RelTime* -> *Scenario Time*

Pass simulated scenario time by argument

addRelTime : *Time* -> *RelTime* -> *Time*

Adjusts *Time* with given time offset.

subTime : *Time* -> *Time* -> *RelTime*

Returns time offset between two given instants.

wholeDays : *RelTime* -> *Int*

Returns the number of whole days in a time offset. Fraction of time is rounded towards zero.

days : *Int* -> *RelTime*

A number of days in relative time.

hours : *Int* -> *RelTime*

A number of hours in relative time.

minutes : *Int* -> *RelTime*

A number of minutes in relative time.

seconds : *Int* -> *RelTime*

A number of seconds in relative time.

milliseconds : *Int* -> *RelTime*

A number of milliseconds in relative time.

microseconds : *Int* -> *RelTime*

A number of microseconds in relative time.

convertRelTimeToMicroseconds : *RelTime* -> *Int*

Convert *RelTime* to microseconds Use higher level functions instead of the internal microseconds

`convertMicrosecondsToRelTime` : *Int* -> *RelTime*

Convert microseconds to RelTime Use higher level functions instead of the internal microseconds

45.3.33 DA.Traversable

Class of data structures that can be traversed from left to right, performing an action on each element. You typically would want to import this module qualified to avoid clashes with functions defined in `Prelude`. Ie.:

```
import DA.Traversable qualified as F
```

45.3.33.1 Typeclasses

class (*Functor* t, *Foldable* t) => *Traversable* t **where**

Functors representing data structures that can be traversed from left to right.

mapA : *Applicative* f => (a -> f b) -> t a -> f (t b)

Map each element of a structure to an action, evaluate these actions from left to right, and collect the results.

sequence : *Applicative* f => t (f a) -> f (t a)

Evaluate each action in the structure from left to right, and collect the results.

instance *Ord* k => *Traversable* (Map k)

instance *Traversable* TextMap

instance *Traversable* Optional

instance *Traversable* NonEmpty

instance *Traversable* (Validation err)

instance *Traversable* (Either a)

instance *Traversable* []

instance *Traversable* a

45.3.33.2 Functions

forA : (*Traversable* t, *Applicative* f) => t a -> (a -> f b) -> f (t b)

`forA` is `mapA` with its arguments flipped.

45.3.34 DA.Tuple

Tuple - Ubiquitous functions of tuples.

45.3.34.1 Functions

first : $(a \rightarrow a') \rightarrow (a, b) \rightarrow (a', b)$

The pair obtained from a pair by application of a programmer supplied function to the argument pair's first field.

second : $(b \rightarrow b') \rightarrow (a, b) \rightarrow (a, b')$

The pair obtained from a pair by application of a programmer supplied function to the argument pair's second field.

both : $(a \rightarrow b) \rightarrow (a, a) \rightarrow (b, b)$

The pair obtained from a pair by application of a programmer supplied function to both the argument pair's first and second fields.

swap : $(a, b) \rightarrow (b, a)$

The pair obtained from a pair by permuting the order of the argument pair's first and second fields.

dupe : $a \rightarrow (a, a)$

Duplicate a single value into a pair.

> dupe 12 == (12, 12)

fst3 : $(a, b, c) \rightarrow a$

Extract the 'fst' of a triple.

snd3 : $(a, b, c) \rightarrow b$

Extract the 'snd' of a triple.

thd3 : $(a, b, c) \rightarrow c$

Extract the final element of a triple.

curry3 : $((a, b, c) \rightarrow d) \rightarrow a \rightarrow b \rightarrow c \rightarrow d$

Converts an uncurried function to a curried function.

uncurry3 : $(a \rightarrow b \rightarrow c \rightarrow d) \rightarrow (a, b, c) \rightarrow d$

Converts a curried function to a function on a triple.

45.3.35 DA.Validation

Validation type and associated functions.

45.3.35.1 Data Types

data `Validation err a`

A `Validation` represents either a non-empty list of errors, or a successful value. This generalizes `Either` to allow more than one error to be collected.

`Errors (NonEmpty err)`

`Success a`

instance `Foldable (Validation err)`

instance `Applicative (Validation err)`

instance `Semigroup (Validation err a)`

instance `Traversable (Validation err)`

instance `Functor (Validation err)`

instance `(Eq err, Eq a) => Eq (Validation err a)`

instance `(Show err, Show a) => Show (Validation err a)`

45.3.35.2 Functions

invalid : `err -> Validation err a`
Fail for the given reason.

ok : `a -> Validation err a`
Succeed with the given value.

validate : `Either err a -> Validation err a`
Turn an `Either` into a `Validation`.

run : `Validation err a -> Either (NonEmpty err) a`
Convert a `Validation err a` value into an `Either`, taking the non-empty list of errors as the left value.

run1 : `Validation err a -> Either err a`
Convert a `Validation err a` value into an `Either`, taking just the first error as the left value.

runWithDefault : `a -> Validation err a -> a`
Run a `Validation err a` with a default value in case of errors.

(<?>) : `Optional b -> err -> Validation err b`
Convert an `Optional t` into a `Validation err t`, or more generally into an `m t` for any `ActionFail` type `m`.

45.3.36 GHC.Show.Text

45.3.36.1 Functions

showsPrecText : *Int* -> *Text* -> ShowS

45.3.37 GHC.Tuple.Check

45.3.37.1 Functions

userWrittenTuple : *a* -> *a*

45.4 Daml Script Library

The Daml Script library defines the API used to implement Daml scripts. See [React to Off-Ledger Events: Daml Script](#) for more information on Daml script.

45.4.1 Daml.Script

45.4.1.1 Data Types

data *Commands* *a*

This is used to build up the commands send as part of submit. If you enable the `ApplicativeDo` extension by adding `{-# LANGUAGE ApplicativeDo #-}` at the top of your file, you can use `do`-notation but the individual commands must not depend on each other and the last statement in a `do` block must be of the form `return expr` or `pure expr`.

instance *Functor Commands*

instance *HasSubmit Script Commands*

instance *Applicative Commands*

instance *HasField* "commands" (SubmitCmd *a*) (*Commands a*)

instance *HasField* "commands" (SubmitMustFailCmd *a*) (*Commands a*)

instance *HasField* "commands" (SubmitTreePayload *a*) (*Commands ()*)

data *Disclosure*

instance *Eq Disclosure*

instance *Ord Disclosure*

instance *HasField* "blob" *Disclosure Text*

instance *HasField* "contractId" *Disclosure (ContractId ())*

instance *HasField* "disclosures" (SubmitCmd *a*) [*Disclosure*]

instance *HasField* "disclosures" (SubmitMustFailCmd *a*) [*Disclosure*]

instance [HasField](#) "disclosures" (SubmitTreePayload a) [[Disclosure](#)]

instance [HasField](#) "templateId" [Disclosure TemplateTypeRep](#)

data [InvalidUserId](#)

Thrown if text for a user identifier does not conform to the format restriction.

[InvalidUserId](#)

Field	Type	Description
m	Text	

instance [Eq](#) [InvalidUserId](#)

instance [Show](#) [InvalidUserId](#)

instance [HasFromAnyException](#) [InvalidUserId](#)

instance [HasMessage](#) [InvalidUserId](#)

instance [HasThrow](#) [InvalidUserId](#)

instance [HasToAnyException](#) [InvalidUserId](#)

instance [HasField](#) "m" [InvalidUserId](#) [Text](#)

data [ParticipantName](#)

[ParticipantName](#)

Field	Type	Description
participantName	Text	

instance [HasField](#) "participantName" [ParticipantName](#) [Text](#)

data [PartyDetails](#)

The party details returned by the party management service.

[PartyDetails](#)

Field	Type	Description
party	Party	Party id
displayName	Optional Text	Optional display name
isLocal	Bool	True if party is hosted by the backing participant.

instance [Eq](#) [PartyDetails](#)

instance [Ord](#) [PartyDetails](#)

instance [Show](#) [PartyDetails](#)

instance [HasField](#) "continue" (ListKnownPartiesPayload a) ([[PartyDetails](#)] -> a)

instance [HasField](#) "displayName" [PartyDetails](#) (Optional [Text](#))

instance [HasField](#) "isLocal" [PartyDetails](#) [Bool](#)

instance [HasField](#) "party" [PartyDetails](#) [Party](#)

data [PartyIdHint](#)

A hint to the backing participant what party id to allocate. Must be a valid [PartyIdString](#) (as described in [@value.proto@](#)).

[PartyIdHint](#)

Field	Type	Description
partyIdHint	Text	

instance [HasField](#) "partyIdHint" [PartyIdHint](#) [Text](#)

data [Script](#) a

This is the type of A Daml script. [Script](#) is an instance of [Action](#), so you can use [do](#) notation.

instance [Functor](#) [Script](#)

instance [CanAssert](#) [Script](#)

instance [ActionCatch](#) [Script](#)

instance [ActionThrow](#) [Script](#)

instance [CanAbort](#) [Script](#)

instance [HasSubmit](#) [Script](#) [Commands](#)

instance [HasTime](#) [Script](#)

instance [Action](#) [Script](#)

instance [ActionFail](#) [Script](#)

instance [Applicative](#) [Script](#)

instance [HasField](#) "dummy" ([Script](#) a) ()

instance [HasField](#) "runScript" ([Script](#) a) (() -> Free [ScriptF](#) (a, ()))

data [User](#)

User-info record for a user in the user management service.

[User](#)

Field	Type	Description
userId	UserId	
primaryParty	Optional Party	

instance [Eq](#) [User](#)

instance [Ord](#) [User](#)

instance [Show](#) [User](#)

instance [HasField](#) "continue" (GetUserPayload a) ([Optional](#) [User](#) -> a)

instance [HasField](#) "continue" (ListAllUsersPayload a) ([\[User\]](#) -> a)

instance [HasField](#) "primaryParty" [User](#) ([Optional](#) [Party](#))

instance [HasField](#) "user" (CreateUserPayload a) [User](#)

instance [HasField](#) "userId" [User](#) [UserId](#)

data [UserAlreadyExists](#)

Thrown if a user to be created already exists.

[UserAlreadyExists](#)

Field	Type	Description
userId	UserId	

instance [Eq](#) [UserAlreadyExists](#)

instance [Show](#) [UserAlreadyExists](#)

45.4.1.2 Functions

query : (*Template* t, *HasAgreement* t, *IsParties* p) => p -> *Script* [(*ContractId* t, t)]

Query the set of active contracts of the template that are visible to the given party.

queryFilter : (*Template* c, *HasAgreement* c, *IsParties* p) => p -> (c -> *Bool*) -> *Script* [(*ContractId* c, c)]

Query the set of active contracts of the template that are visible to the given party and match the given predicate.

queryContractId : (Template t, HasAgreement t, IsParties p, HasCallStack) => p -> ContractId t -> Script (Optional t)

Query for the contract with the given contract id.

Returns `None` if there is no active contract the party is a stakeholder on.

WARNING: Over the gRPC and with the JSON API in-memory backend this performs a linear search so only use this if the number of active contracts is small.

This is semantically equivalent to calling `query` and filtering on the client side.

queryInterface : (Template i, HasInterfaceView i v, IsParties p) => p -> Script [(ContractId i, Optional v)]

Query the set of active contract views for an interface that are visible to the given party. If the view function fails for a given contract id, The `Optional v` will be `None`.

WARNING: Information about instances with failed-views is not currently returned over the JSON API: the `Optional v` will be `Some _` for every element in the returned list.

queryInterfaceContractId : (Template i, HasInterfaceView i v, IsParties p, HasCallStack) => p -> ContractId i -> Script (Optional v)

Query for the contract view with the given contract id.

Returns `None` if there is no active contract the party is a stakeholder on.

Returns `None` if the view function fails for the given contract id.

WARNING: Over the gRPC and with the JSON API in-memory backend this performs a linear search so only use this if the number of active contracts is small.

This is semantically equivalent to calling `queryInterface` and filtering on the client side.

queryDisclosure : (Template t, HasAgreement t, IsParties p, HasCallStack) => p -> ContractId t -> Script (Optional Disclosure)

like by `queryContractId` but return the contract as a explicit disclosure blob

WARNING: Over the gRPC this performs a linear search so only use this if the number of active contracts is small. Not supported by JSON API

queryContractKey : (HasCallStack, TemplateKey t k, IsParties p) => p -> k -> Script (Optional (ContractId t, t))

Returns `None` if there is no active contract with the given key that the party is a stakeholder on.

WARNING: Over the gRPC and with the JSON API in-memory backend this performs a linear search so only use this if the number of active contracts is small.

This is semantically equivalent to calling `query` and filtering on the client side.

setTime : HasCallStack => Time -> Script ()

Set the time via the time service.

This is only supported in Daml Studio and `daml test` as well as when running over the gRPC API against a ledger in static time mode.

Note that the ledger time service does not support going backwards in time. However, you can go back in time in Daml Studio.

passTime : RelTime -> Script ()

Advance ledger time by the given interval.

This is only supported in Daml Studio and `daml test` as well as when running over the gRPC API against a ledger in static time mode. Note that this is not an atomic operation over the gRPC API so no other clients should try to change time while this is running.

Note that the ledger time service does not support going backwards in time. However, you can go back in time in Daml Studio.

allocateParty : HasCallStack => Text -> Script Party

Allocate a party with the given display name using the party management service.

allocatePartyWithHint : HasCallStack => Text -> PartyIdHint -> Script Party

Allocate a party with the given display name and id hint using the party management service.

allocatePartyOn : *Text* -> *ParticipantName* -> *Script Party*

Allocate a party with the given display name on the specified participant using the party management service.

allocatePartyWithHintOn : *Text* -> *PartyIdHint* -> *ParticipantName* -> *Script Party*

Allocate a party with the given display name and id hint on the specified participant using the party management service.

listKnownParties : *HasCallStack* => *Script [PartyDetails]*

List the parties known to the default participant.

listKnownPartiesOn : *HasCallStack* => *ParticipantName* -> *Script [PartyDetails]*

List the parties known to the given participant.

sleep : *HasCallStack* => *RelTime* -> *Script ()*

Sleep for the given duration.

This is primarily useful in tests where you repeatedly call `query` until a certain state is reached. Note that this will sleep for the same duration in both wall clock and static time mode.

submitWithDisclosures : *HasCallStack* => *Party* -> *[Disclosure]* -> *Commands a* -> *Script a*

`submitWithDisclosures p disc cmds` submits the commands `cmds` as a single transaction from party `p` with the explicit disclosures `disc` and returns the value returned by `cmds`. If the transaction fails, `submit` also fails.

submitWithDisclosuresMustFail : *HasCallStack* => *Party* -> *[Disclosure]* -> *Commands a* -> *Script ()*

`submitWithDisclosures p disc cmds` submits the commands `cmds` as a single transaction from party `p` with the explicit disclosures `disc`. It only succeeds if the submitting the transaction fails.

submitMulti : *HasCallStack* => *[Party]* -> *[Party]* -> *Commands a* -> *Script a*

`submitMulti actAs readAs cmds` submits `cmds` as a single transaction authorized by `actAs`. Fetched contracts must be visible to at least one party in the union of `actAs` and `readAs`.

submitMultiMustFail : *HasCallStack* => *[Party]* -> *[Party]* -> *Commands a* -> *Script ()*

`submitMultiMustFail actAs readAs cmds` behaves like `submitMulti actAs readAs cmds` but fails when `submitMulti` succeeds and the other way around.

submitMultiWithDisclosures : *HasCallStack* => *[Party]* -> *[Party]* -> *[Disclosure]* -> *Commands a* -> *Script a*

`submitMultiWithDisclosures actAs readAs disc cmds` submits `cmds` as a single transaction authorized by `actAs` with explicit disclosures `disc`. Fetched contracts, except explicit disclosed ones, must be visible to at least one party in the union of `actAs` and `readAs`.

submitMultiWithDisclosuresMustFail : *HasCallStack* => *[Party]* -> *[Party]* -> *[Disclosure]* -> *Commands a* -> *Script ()*

`submitMultiWithDisclosuresMustFail actAs readAs disc cmds` behaves like `submitMultiWithDisclosures actAs readAs disc cmds` but fails when `submitMulti` succeeds and the other way around.

createCmd : (*Template t*, *HasAgreement t*) => *t* -> *Commands (ContractId t)*

Create a contract of the given template.

exerciseCmd : *Choice t c r* => *ContractId t* -> *c* -> *Commands r*

Exercise a choice on the given contract.

exerciseByKeyCmd : (*TemplateKey t k*, *Choice t c r*) => *k* -> *c* -> *Commands r*

Exercise a choice on the contract with the given key.

createAndExerciseCmd : (Template t, Choice t c r, HasAgreement t) => t -> c -> Commands r
Create a contract and exercise a choice on it in the same transaction.

archiveCmd : Choice t Archive () => ContractId t -> Commands ()
Archive the given contract.
archiveCmd cid is equivalent to exerciseCmd cid Archive.

script : Script a -> Script a
Convenience helper to declare you are writing a Script.
This is only useful for readability and to improve type inference. Any expression of type Script a is a valid script regardless of whether it is implemented using script or not.

userIdToText : UserId -> Text
Extract the name-text from a user identifier.

validateUserId : HasCallStack => Text -> Script UserId
Construct a user identifier from text. May throw InvalidUserId.

createUser : HasCallStack => User -> [UserRight] -> Script ()
Create a user with the given rights. May throw UserAlreadyExists.

createUserOn : HasCallStack => User -> [UserRight] -> ParticipantName -> Script ()
Create a user with the given rights on the given participant. May throw UserAlreadyExists.

getUser : HasCallStack => UserId -> Script User
Fetch a user record by user id. May throw UserNotFound.

getUserOn : HasCallStack => UserId -> ParticipantName -> Script User
Fetch a user record by user id from the given participant. May throw UserNotFound.

listAllUsers : Script [User]
List all users. This function may make multiple calls to underlying paginated ledger API.

listAllUsersOn : ParticipantName -> Script [User]
List all users on the given participant. This function may make multiple calls to underlying paginated ledger API.

grantUserRights : HasCallStack => UserId -> [UserRight] -> Script [UserRight]
Grant rights to a user. Returns the rights that have been newly granted. May throw UserNotFound.

grantUserRightsOn : HasCallStack => UserId -> [UserRight] -> ParticipantName -> Script [UserRight]
Grant rights to a user on the given participant. Returns the rights that have been newly granted. May throw UserNotFound.

revokeUserRights : HasCallStack => UserId -> [UserRight] -> Script [UserRight]
Revoke rights for a user. Returns the revoked rights. May throw UserNotFound.

revokeUserRightsOn : HasCallStack => UserId -> [UserRight] -> ParticipantName -> Script [UserRight]
Revoke rights for a user on the given participant. Returns the revoked rights. May throw UserNotFound.

deleteUser : HasCallStack => UserId -> Script ()
Delete a user. May throw UserNotFound.

deleteUserOn : HasCallStack => UserId -> ParticipantName -> Script ()
Delete a user on the given participant. May throw UserNotFound.

listUserRights : *HasCallStack* => *UserId* -> *Script* [*UserRight*]

List the rights of a user. May throw *UserNotFound*.

listUserRightsOn : *HasCallStack* => *UserId* -> *ParticipantName* -> *Script* [*UserRight*]

List the rights of a user on the given participant. May throw *UserNotFound*.

submitUser : *HasCallStack* => *UserId* -> *Commands* a -> *Script* a

Submit the commands with the *actAs* and *readAs* claims granted to a user. May throw *UserNotFound*.

submitUserOn : *HasCallStack* => *UserId* -> *ParticipantName* -> *Commands* a -> *Script* a

Submit the commands with the *actAs* and *readAs* claims granted to the user on the given participant. May throw *UserNotFound*.

45.5 Daml Trigger Library

The Daml Trigger library defines the API used to declare a Daml trigger. See [React to On-Ledger Events: Daml Triggers \(Deprecated\)](#) for more information on Daml triggers.

45.5.1 Daml.Trigger

45.5.1.1 Typeclasses

class *ActionTriggerAny* m **where**

Features possible in *initialize*, *updateState*, and *rule*.

queryContractId : *Template* a => *ContractId* a -> m (*Optional* a)

Find the contract with the given *id* in the ACS, if present.

getReadAs : m [*Party*]

getActAs : m *Party*

instance *ActionTriggerAny* (*TriggerA* s)

instance *ActionTriggerAny* *TriggerInitializeA*

instance *ActionTriggerAny* (*TriggerUpdateA* s)

class *ActionTriggerAny* m => *ActionTriggerUpdate* m **where**

Features possible in *updateState* and *rule*.

getCommandsInFlight : m (*Map* *CommandId* [*Command*])

Retrieve command submissions made by this trigger that have not yet completed. If the trigger has restarted, it will not contain commands from before the restart; therefore, this should be treated as an optimization rather than an absolute authority on ledger state.

instance *ActionTriggerUpdate* (*TriggerA* s)

instance *ActionTriggerUpdate* (*TriggerUpdateA* s)

45.5.1.2 Data Types

data `Trigger s`

This is the type of your trigger. `s` is the user-defined state type which you can often leave at `()`.

`Trigger`

Field	Type	Description
<code>initialize</code>	<code>TriggerInitializeA s</code>	Initialize the user-defined state based on the ACS.
<code>updateState</code>	<code>Message -> TriggerUpdateA s ()</code>	Update the user-defined state based on a transaction or completion message. It can manipulate the state with <code>get</code> , <code>put</code> , and <code>modify</code> , or query the ACS with <code>query</code> .
<code>rule</code>	<code>Party -> TriggerA s ()</code>	The rule defines the main logic of your trigger. It can send commands to the ledger using <code>emitCommands</code> to change the ACS. The rule depends on the following arguments: * The party your trigger is running as. * The user-defined state. and can retrieve other data with functions in <code>TriggerA</code> : * The current state of the ACS. * The current time (UTC in wall-clock mode, Unix epoch in static mode) * The commands in flight.
<code>registeredTemplates</code>	<code>RegisteredTemplates</code>	The templates the trigger will receive events for.
<code>heartbeat</code>	<code>Optional RelTime</code>	Send a heartbeat message at the given interval.

instance `HasField` "heartbeat" (`Trigger s`) (`Optional RelTime`)

instance `HasField` "initialize" (`Trigger s`) (`TriggerInitializeA s`)

instance `HasField` "registeredTemplates" (`Trigger s`) `RegisteredTemplates`

instance `HasField` "rule" (`Trigger s`) (`Party -> TriggerA s ()`)

instance `HasField` "updateState" (`Trigger s`) (`Message -> TriggerUpdateA s ()`)

data `TriggerA s a`

`TriggerA` is the type used in the `rule` of a Daml trigger. Its main feature is that you can call `emitCommands` to send commands to the ledger.

instance `ActionTriggerAny` (`TriggerA s`)

instance `ActionTriggerUpdate` (`TriggerA s`)

instance `Functor` (`TriggerA s`)

instance `ActionState s` (`TriggerA s`)

```
instance HasTime (TriggerA s)
instance Action (TriggerA s)
instance Applicative (TriggerA s)
instance HasField "rule" (Trigger s) (Party -> TriggerA s ())
instance HasField "runTriggerA" (TriggerA s a) (ACS -> TriggerRule (TriggerAState s) a)
```

data *TriggerInitializeA* a

TriggerInitializeA is the type used in the `initialize` of a Daml trigger. It can query, but not emit commands or update the state.

```
instance ActionTriggerAny TriggerInitializeA
instance Functor TriggerInitializeA
instance Action TriggerInitializeA
instance Applicative TriggerInitializeA
instance HasField "initialize" (Trigger s) (TriggerInitializeA s)
instance HasField "runTriggerInitializeA" (TriggerInitializeA a) (TriggerInitState -> a)
```

data *TriggerUpdateA* s a

TriggerUpdateA is the type used in the `updateState` of a Daml trigger. It has similar actions in common with *TriggerA*, but cannot use `emitCommands` or `getTime`.

```
instance ActionTriggerAny (TriggerUpdateA s)
instance ActionTriggerUpdate (TriggerUpdateA s)
instance Functor (TriggerUpdateA s)
instance ActionState s (TriggerUpdateA s)
instance Action (TriggerUpdateA s)
instance Applicative (TriggerUpdateA s)
instance HasField "runTriggerUpdateA" (TriggerUpdateA s a) (TriggerUpdateState -> State s a)
instance HasField "updateState" (Trigger s) (Message -> TriggerUpdateA s ())
```

45.5.1.3 Functions

query : (Template a, ActionTriggerAny m) => m [(ContractId a, a)]

Extract the contracts of a given template from the ACS.

queryFilter : (Functor m, Template a, ActionTriggerAny m) => (a -> Bool) -> m [(ContractId a, a)]

Extract the contracts of a given template from the ACS and filter to those that match the predicate.

queryContractKey : (Template a, HasKey a k, Eq k, ActionTriggerAny m, Functor m) => k -> m (Optional (ContractId a, a))

Find the contract with the given `key` in the ACS, if present.

emitCommands : [Command] -> [AnyContractId] -> TriggerA s CommandId

Send a transaction consisting of the given commands to the ledger. The second argument can be used to mark a list of contract ids as pending. These contracts will automatically be filtered from getContracts until we either get the corresponding transaction event for this command or a failing completion.

emitCommandsV2 : [Command] -> [AnyContractId] -> TriggerA s (Optional CommandId)

dedupCreate : (Eq t, Template t, HasAgreement t) => t -> TriggerA s ()

Create the template if it's not already in the list of commands in flight (it will still be created if it is in the ACS).

Note that this will send the create as a single-command transaction. If you need to send multiple commands in one transaction, use emitCommands with createCmd and handle filtering yourself.

dedupCreateAndExercise : (Eq t, Eq c, Template t, Choice t c r) => t -> c -> TriggerA s ()

Create the template and exercise a choice on it if it's not already in the list of commands in flight (it will still be created if it is in the ACS).

Note that this will send the create and exercise as a single-command transaction. If you need to send multiple commands in one transaction, use emitCommands with createAndExerciseCmd and handle filtering yourself.

dedupExercise : (Eq c, Choice t c r) => ContractId t -> c -> TriggerA s ()

Exercise the choice on the given contract if it is not already in flight.

Note that this will send the exercise as a single-command transaction. If you need to send multiple commands in one transaction, use emitCommands with exerciseCmd and handle filtering yourself.

If you are calling a consuming choice, you might be better off by using emitCommands and adding the contract id to the pending set.

dedupExerciseByKey : (Eq c, Eq k, Choice t c r, TemplateKey t k) => k -> c -> TriggerA s ()

Exercise the choice on the given contract if it is not already in flight.

Note that this will send the exercise as a single-command transaction. If you need to send multiple commands in one transaction, use emitCommands with exerciseCmd and handle filtering yourself.

runTrigger : Trigger s -> BatchTrigger (TriggerState s)

Transform the high-level trigger type into the batching trigger from Daml.Trigger.LowLevel.

45.5.2 Daml.Trigger.Assert

45.5.2.1 Data Types

data ACSBuilder

Used to construct an 'ACS' for 'testRule'.

instance Monoid ACSBuilder

instance Semigroup ACSBuilder

45.5.2.2 Functions

toACS : (Template t, HasAgreement t) => ContractId t -> ACSBuilder

Include the given contract in the 'ACS'. Note that the `ContractId` must point to an active contract.

testRule : Trigger s -> Party -> [Party] -> ACSBuilder -> Map CommandId [Command] -> s -> Script (s, [Commands])

Execute a trigger's rule once in a scenario.

flattenCommands : [Commands] -> [Command]

Drop 'CommandId's and extract all 'Command's.

assertCreateCmd : (Template t, HasAgreement t, CanAbort m) => [Command] -> (t -> Either Text ()) -> m ()

Check that at least one command is a create command whose payload fulfills the given assertions.

assertExerciseCmd : (Template t, HasAgreement t, Choice t c r, CanAbort m) => [Command] -> ((ContractId t, c) -> Either Text ()) -> m ()

Check that at least one command is an exercise command whose contract id and choice argument fulfill the given assertions.

assertExerciseByKeyCmd : (TemplateKey t k, Choice t c r, CanAbort m) => [Command] -> ((k, c) -> Either Text ()) -> m ()

Check that at least one command is an exercise by key command whose key and choice argument fulfill the given assertions.

45.5.3 Daml.Trigger.LowLevel

45.5.3.1 Typeclasses

class HasTime m => ActionTrigger m **where**

Low-level trigger actions.

liftTF : TriggerF a -> m a

instance ActionTrigger (TriggerRule s)

instance ActionTrigger TriggerSetup

45.5.3.2 Data Types

data ActiveContracts

ActiveContracts

Field	Type	Description
activeContracts	[Created]	

instance HasField "acs" TriggerSetupArguments ActiveContracts

instance HasField "activeContracts" ActiveContracts [Created]

```
instance HasField "initialState" (Trigger s) (Party -> [Party] -> ActiveContracts -> TriggerSetup s)
```

data [AnyContractId](#)

This type represents the contract id of an unknown template. You can use `fromAnyContractId` to check which template it corresponds to.

```
instance Eq AnyContractId
```

```
instance Ord AnyContractId
```

```
instance Show AnyContractId
```

```
instance HasField "activeContracts" ACS (Map TemplateTypeRep (Map AnyContractId AnyTemplate))
```

```
instance HasField "contractId" AnyContractId (ContractId ())
```

```
instance HasField "contractId" Archived AnyContractId
```

```
instance HasField "contractId" Command AnyContractId
```

```
instance HasField "contractId" Created AnyContractId
```

```
instance HasField "pendingContracts" ACS (Map CommandId [AnyContractId])
```

```
instance HasField "pendingContracts" (TriggerAState s) (Map CommandId [AnyContractId])
```

```
instance HasField "templateId" AnyContractId TemplateTypeRep
```

data [Archived](#)

The data in an `Archived` event.

[Archived](#)

Field	Type	Description
<code>eventId</code>	EventId	
<code>contractId</code>	AnyContractId	

```
instance Eq Archived
```

```
instance Show Archived
```

```
instance HasField "contractId" Archived AnyContractId
```

```
instance HasField "eventId" Archived EventId
```

data [BatchTrigger](#) s

Batching trigger is (approximately) a left-fold over `Message` with an accumulator of type `s`.

[BatchTrigger](#)

Field	Type	Description
initialState	TriggerSetupArguments -> TriggerSetup s	
update	[Message] -> TriggerRule s ()	
registeredTemplates	RegisteredTemplates	
heartbeat	Optional RelTime	

instance [HasField](#) "heartbeat" ([BatchTrigger s](#)) ([Optional RelTime](#))

instance [HasField](#) "initialState" ([BatchTrigger s](#)) ([TriggerSetupArguments](#) -> [TriggerSetup s](#))

instance [HasField](#) "registeredTemplates" ([BatchTrigger s](#)) [RegisteredTemplates](#)

instance [HasField](#) "update" ([BatchTrigger s](#)) ([\[Message\]](#) -> [TriggerRule s](#) ())

data [Command](#)

A ledger API command. To construct a command use `createCmd` and `exerciseCmd`.

[CreateCommand](#)

Field	Type	Description
templateArg	AnyTemplate	

[ExerciseCommand](#)

Field	Type	Description
contractId	AnyContractId	
choiceArg	AnyChoice	

[CreateAndExerciseCommand](#)

Field	Type	Description
templateArg	AnyTemplate	
choiceArg	AnyChoice	

[ExerciseByKeyCommand](#)

Field	Type	Description
tplTypeRep	Template-TypeRep	
contractKey	AnyContractKey	
choiceArg	AnyChoice	

instance [HasField](#) "choiceArg" [Command](#) [AnyChoice](#)

instance [HasField](#) "commands" [Commands](#) [[Command](#)]

instance [HasField](#) "commandsInFlight" (TriggerAState s) ([Map](#) [CommandId](#) [[Command](#)])

instance [HasField](#) "commandsInFlight" (TriggerState s) ([Map](#) [CommandId](#) [[Command](#)])

instance [HasField](#) "commandsInFlight" TriggerUpdateState ([Map](#) [CommandId](#) [[Command](#)])

instance [HasField](#) "commandId" [Transaction](#) ([Optional](#) [CommandId](#))

instance [HasField](#) "commandsInFlight" (TriggerAState s) ([Map](#) [CommandId](#) [[Command](#)])

instance [HasField](#) "commandsInFlight" (TriggerState s) ([Map](#) [CommandId](#) [[Command](#)])

instance [HasField](#) "commandsInFlight" TriggerUpdateState ([Map](#) [CommandId](#) [[Command](#)])

instance [HasField](#) "pendingContracts" ACS ([Map](#) [CommandId](#) [[AnyContractId](#)])

instance [HasField](#) "pendingContracts" (TriggerAState s) ([Map](#) [CommandId](#) [[AnyContractId](#)])

data [Commands](#)

A set of commands that are submitted as a single transaction.

[Commands](#)

Field	Type	Description
commandId	CommandId	
commands	[Command]	

instance [HasField](#) "commandId" [Commands](#) [CommandId](#)

instance [HasField](#) "commands" [Commands](#) [[Command](#)]

data [Completion](#)

A completion message. Note that you will only get completions for commands emitted from the trigger. Contrary to the ledger API completion stream, this also includes synchronous failures.

[Completion](#)

Field	Type	Description
commandId	CommandId	
status	Completion-Status	

instance [Show Completion](#)

instance [HasField](#) "commandId" [Completion](#) [CommandId](#)

instance [HasField](#) "status" [Completion](#) [CompletionStatus](#)

data [CompletionStatus](#)

[Failed](#)

Field	Type	Description
status	Int	
message	Text

45.5.3.3 Functions

toAnyContractId : [Template](#) t => [ContractId](#) t -> [AnyContractId](#)

Wrap a [ContractId](#) t in [AnyContractId](#).

fromAnyContractId : [Template](#) t => [AnyContractId](#) -> [Optional](#) ([ContractId](#) t)

Check if a [AnyContractId](#) corresponds to the given template or return [None](#) otherwise.

fromCreated : [Template](#) t => [Created](#) -> [Optional](#) ([EventId](#), [ContractId](#) t, t)

Check if a [Created](#) event corresponds to the given template.

fromArchived : [Template](#) t => [Archived](#) -> [Optional](#) ([EventId](#), [ContractId](#) t)

Check if an [Archived](#) event corresponds to the given template.

registeredTemplate : [Template](#) t => [RegisteredTemplate](#)

createCmd : ([Template](#) t, [HasAgreement](#) t) => t -> [Command](#)

Create a contract of the given template.

exerciseCmd : [Choice](#) t c r => [ContractId](#) t -> c -> [Command](#)

Exercise the given choice.

createAndExerciseCmd : ([Template](#) t, [Choice](#) t c r) => t -> c -> [Command](#)

Create a contract of the given template and immediately exercise the given choice on it.

exerciseByKeyCmd : ([Choice](#) t c r, [TemplateKey](#) t k) => k -> c -> [Command](#)

fromCreate : [Template](#) t => [Command](#) -> [Optional](#) t

Check if the command corresponds to a create command for the given template.

fromCreateAndExercise : ([Template](#) t, [Choice](#) t c r) => [Command](#) -> [Optional](#) (t, c)

Check if the command corresponds to a create and exercise command for the given template.

fromExercise : [Choice](#) t c r => [Command](#) -> [Optional](#) ([ContractId](#) t, c)

Check if the command corresponds to an exercise command for the given template.

fromExerciseByKey : ([Choice](#) t c r, [TemplateKey](#) t k) => [Command](#) -> [Optional](#) (k, c)

Check if the command corresponds to an exercise by key command for the given template.

execStateT : *Functor* m => StateT s m a -> s -> m s

zoom : *Functor* m => (t -> s) -> (t -> s -> t) -> StateT s m a -> StateT t m a

simulateRule : *TriggerRule* s a -> *Time* -> s -> (s, [*Commands*], a)

Run a rule without running it. May lose information from the rule; meant for testing purposes only.

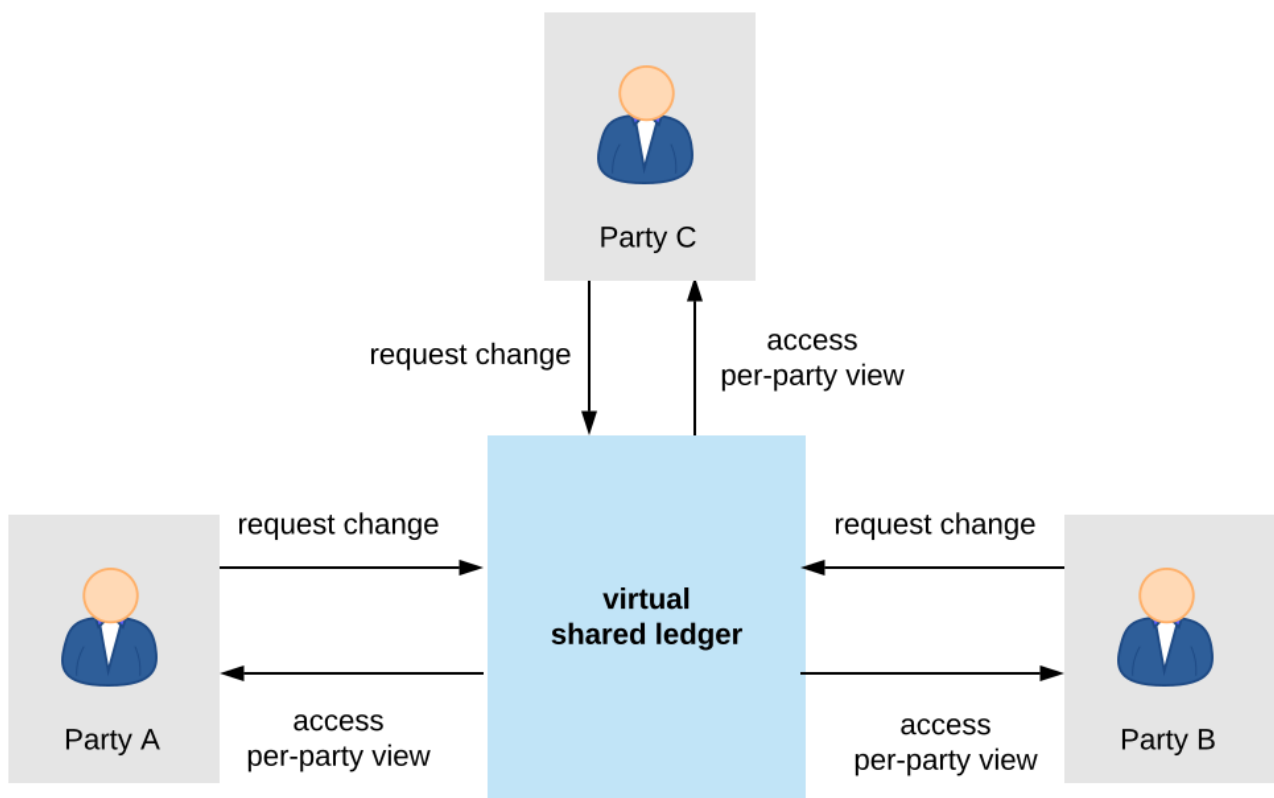

submitCommands : *ActionTrigger* m => [*Command*] -> m *CommandId*

Chapter 46

Daml Ledger References

46.1 Daml Ledger Model Concepts

Daml Ledgers enable multi-party workflows by providing parties with a virtual *shared ledger*, which encodes the current state of their shared contracts, written in Daml. At a high level, the interactions are visualized as follows:

The Daml ledger model defines:

1. what the ledger looks like - the structure of Daml ledgers
2. who can request which changes - the integrity model for Daml ledgers
3. who sees which changes and data - the privacy model for Daml ledgers

The below sections review these concepts of the ledger model in turn. They also briefly describe the

link between Daml and the model.

46.1.1 Structure

This section looks at the structure of a Daml ledger and the associated ledger changes. The basic building blocks of changes are *actions*, which get grouped into *transactions*.

46.1.1.1 Actions and Transactions

One of the main features of the Daml ledger model is a *hierarchical action structure*.

This structure is illustrated below on a toy example of a multi-party interaction. Alice (A) gets some digital cash, in the form of an I-Owe-You (IOU for short) from a bank, and she needs her house painted. She gets an offer from a painter (P) with reference number P123 to paint her house in exchange for this IOU. Lastly, A accepts the offer, transferring the money and signing a contract with P, whereby he is promising to paint her house.

This acceptance can be viewed as A *exercising* her right to accept the offer. Her acceptance has two consequences. First, A transfers her IOU, that is, *exercises* her right to transfer the IOU, after which a new IOU for P is created. Second, a new contract is *created* that requires P to paint A's house.

Thus, the acceptance in this example is reduced to two types of actions: (1) creating contracts, and (2) exercising rights on them. These are also the two main kinds of actions in the Daml ledger model. The visual notation below records the relations between the actions during the above acceptance.

Formally, an **action** is one of the following:

1. a **Create** action on a contract, which records the creation of the contract
2. an **Exercise** action on a contract, which records that one or more parties have exercised a right they have on the contract, and which also contains:
 1. An associated set of parties called **actors**. These are the parties who perform the action.
 2. An exercise **kind**, which is either **consuming** or **non-consuming**. Once consumed, a contract cannot be used again (for example, Alice should not be able to accept the painter's offer twice). Contracts exercised in a non-consuming fashion can be reused.
 3. A list of **consequences**, which are themselves actions. Note that the consequences, as well as the kind and the actors, are considered a part of the exercise action itself. This nesting of actions within other actions through consequences of exercises gives rise to the hierarchical structure. The exercise action is the **parent action** of its consequences.

3. a **Fetch** action on a contract, which demonstrates that the contract exists and is active at the time of fetching. The action also contains **actors**, the parties who fetch the contract. A **Fetch** behaves like a non-consuming exercise with no consequences, and can be repeated.
4. a **Key assertion**, which records the assertion that the given [contract key](#) is **not** assigned to any unconsumed contract on the ledger.

An **Exercise** or a **Fetch** action on a contract is said to **use** the contract. Moreover, a consuming **Exercise** is said to **consume** (or **archive**) its contract.

The following EBNF-like grammar summarizes the structure of actions and transactions. Here, $s \mid t$ represents the choice between s and t , st represents s followed by t , and s^* represents the repetition of s zero or more times. The terminal ‘contract’ denotes the underlying type of contracts, and the terminal ‘party’ the underlying type of parties.

```

Action      ::= 'Create' contract
              | 'Exercise' party* contract Kind Transaction
              | 'Fetch' party* contract
              | 'NoSuchKey' key
Transaction ::= Action*
Kind         ::= 'Consuming' | 'NonConsuming'

```

The visual notation presented earlier captures actions precisely with conventions that:

1. **Exercise** denotes consuming, **ExerciseN** non-consuming exercises, and **Fetch** a fetch.
2. double arrows connect exercises to their consequences, if any.
3. the consequences are ordered left-to-right.
4. to aid intuitions, exercise actions are annotated with suggestive names like `accept` or `transfer`. Intuitively, these correspond to names of Daml choices, but they have no semantic meaning.

An alternative shorthand notation, shown below uses the abbreviations **Exe** and **ExeN** for exercises, and omits the **Create** labels on create actions.

To show an example of a non-consuming exercise, consider a different offer example with an easily replenishable subject. For example, if P was a car manufacturer, and A a car dealer, P could make an offer that could be accepted multiple times.

To see an example of a fetch, we can extend this example to the case where *P* produces exclusive cars and allows only certified dealers to sell them. Thus, when accepting the offer, *A* has to additionally show a valid quality certificate issued by some standards body *S*.

In the paint offer example, the underlying type of contracts consists of three sorts of contracts:

PaintOffer houseOwner painter obligor refNo Intuitively an offer (with a reference number) by which the painter proposes to the house owner to paint her house, in exchange for a single IOU token issued by the specified obligor.

PaintAgree painter houseOwner refNo Intuitively a contract whereby the painter agrees to paint the owner's house

Iou obligor owner An IOU token from an obligor to an owner (for simplicity, the token is of unit amount).

In practice, multiple IOU contracts can exist between the same *obligor* and *owner*, in which case each contract should have a unique identifier. However, in this section, each contract only appears once, allowing us to drop the notion of identifiers for simplicity reasons.

A **transaction** is a list of actions. Thus, the consequences of an exercise form a transaction. In the example, the consequences of Alice's exercise form the following transaction, where actions are again ordered left-to-right.

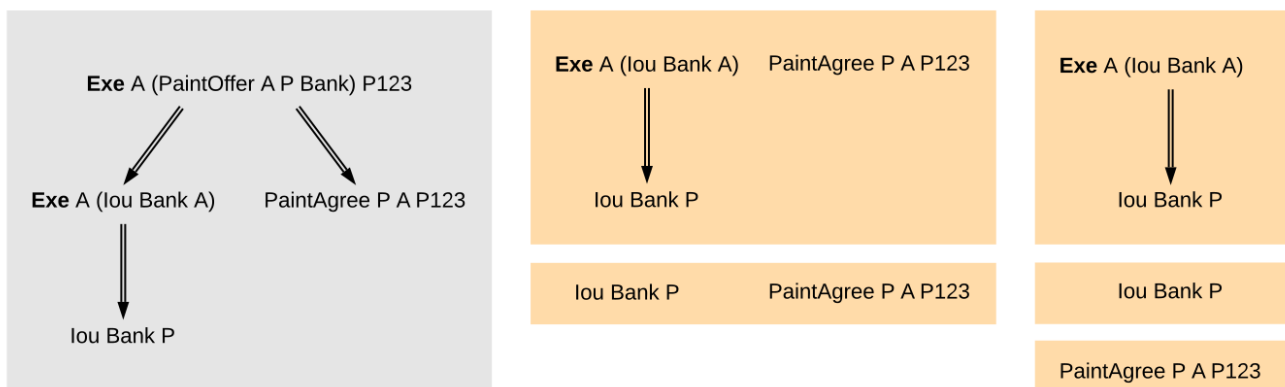

For an action act, its **proper subactions** are all actions in the consequences of act, together with all of their proper subactions. Additionally, act is a (non-proper) **subaction** of itself.

The subaction relation is visualized below. Both the green and yellow boxes are proper subactions of Alice's exercise on the paint offer. Additionally, the creation of *lou Bank P* (yellow box) is also a proper subaction of the exercise on the *lou Bank A*.

Similarly, a **subtransaction** of a transaction is either the transaction itself, or a **proper subtransaction**: a transaction obtained by removing at least one action, or replacing it by a subtransaction of its consequences. For example, given the transaction consisting of just one action, the paint offer acceptance, the image below shows all its proper non-empty subtransactions on the right (yellow boxes).

To illustrate [contract keys](#), suppose that the contract key for a *PaintOffer* consists of the reference number and the painter. So Alice can refer to the *PaintOffer* by its key (*P*, *P123*). To make this explicit, we use the notation *PaintOffer @P A &P123* for contracts, where @ and & mark the parts that belong to a key. (The difference between @ and & will be explained in the [integrity section](#).) The ledger integrity

constraints in the next section ensure that there is always at most one active *PaintOffer* for a given key. So if the painter retracts its *PaintOffer* and later Alice tries to accept it, she can then record the absence with a *NoSuchKey* (*P*, *P123*) key assertion.

46.1.1.2 Ledgers

The transaction structure records the contents of the changes, but not *who requested them*. This information is added by the notion of a **commit**: a transaction paired with the parties that requested it, called the **requesters** of the commit. A commit may have one or more requesters. Given a commit (*p*, *tx*) with transaction $tx = act_1, \dots, act_n$, every act_i is called a **top-level action** of the commit. A **ledger** is a sequence of commits. A top-level action of any ledger commit is also a top-level action of the ledger.

The following EBNF grammar summarizes the structure of commits and ledgers:

```
Commit    ::= party+ Transaction
Ledger    ::= Commit*
```

A Daml ledger thus represents the full history of all actions taken by parties.¹ Since the ledger is a sequence (of dependent actions), it induces an *order* on the commits in the ledger. Visually, a ledger can be represented as a sequence growing from left to right as time progresses. Below, dashed vertical lines mark the boundaries of commits, and each commit is annotated with its requester(s). Arrows link the create and exercise actions on the same contracts. These additional arrows highlight that the ledger forms a **transaction graph**. For example, the aforementioned house painting scenario is visually represented as follows.

The definitions presented here are all the ingredients required to *record* the interaction between parties in a Daml ledger. That is, they address the first question: what do changes and ledgers look like? . To answer the next question, who can request which changes , a precise definition is needed of which ledgers are permissible, and which are not. For example, the above paint offer ledger is intuitively permissible, while all of the following ledgers are not.

The next section discusses the criteria that rule out the above examples as invalid ledgers.

¹ Calling such a complete record *ledger* is standard in the distributed ledger technology community. In accounting terminology, this record is closer to a *journal* than to a *ledger*.

Fig. 1: Alice spending her IOU twice (double spend), once transferring it to *B* and once to *P*.

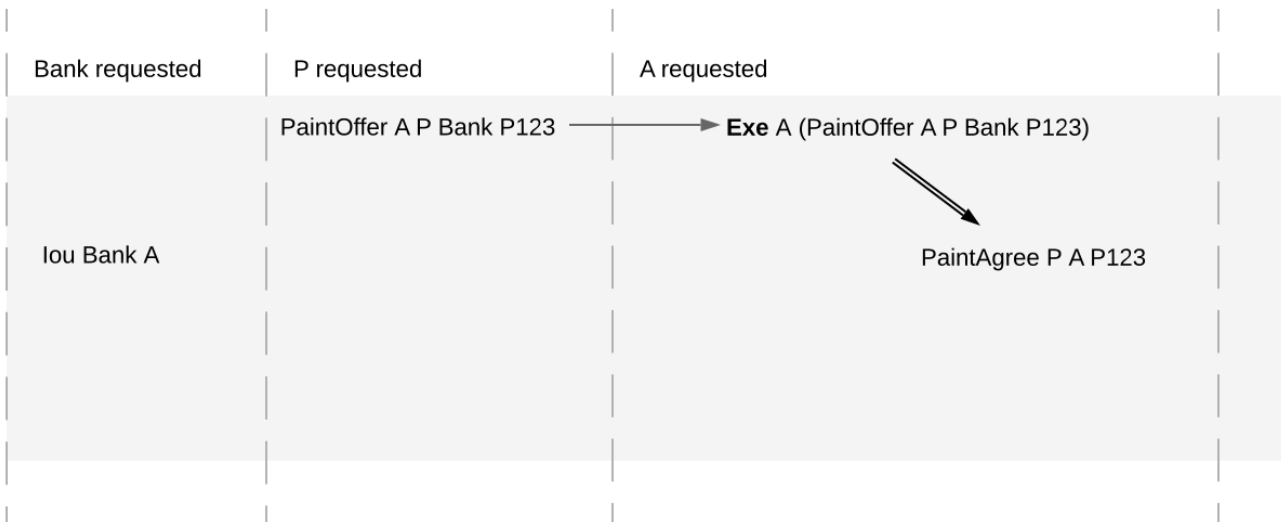

Fig. 2: Alice changing the offer's outcome by removing the transfer of the *Iou*.

Fig. 3: An obligation imposed on the painter without his consent.

Fig. 4: Painter stealing Alice’s IOU. Note that the ledger would be intuitively permissible if it was Alice performing the last commit.

Fig. 5: Painter falsely claiming that there is no offer.

Fig. 6: Painter trying to create two different paint offers with the same reference number.

46.1.2 Integrity

This section addresses the question of who can request which changes.

46.1.2.1 Valid Ledgers

At the core is the concept of a *valid ledger*; changes are permissible if adding the corresponding commit to the ledger results in a valid ledger. **Valid ledgers** are those that fulfill three conditions:

Consistency Exercises and fetches on inactive contracts are not allowed, i.e. contracts that have not yet been created or have already been consumed by an exercise. A contract with a contract key can be created only if the key is not associated to another unconsumed contract, and all key assertions hold.

Conformance Only a restricted set of actions is allowed on a given contract.

Authorization The parties who may request a particular change are restricted.

Only the last of these conditions depends on the party (or parties) requesting the change; the other two are general.

46.1.2.2 Consistency

Consistency consists of two parts:

1. **Contract consistency**: Contracts must be created before they are used, and they cannot be used once they are consumed.
2. **Key consistency**: Keys are unique and key assertions are satisfied.

To define this precisely, notions of *before* and *after* are needed. These are given by putting all actions in a sequence. Technically, the sequence is obtained by a pre-order traversal of the ledger's actions, noting that these actions form an (ordered) forest. Intuitively, it is obtained by always picking parent actions before their proper subactions, and otherwise always picking the actions on the left before the actions on the right. The image below depicts the resulting order on the paint offer example:

In the image, an action *act* happens before action *act'* if there is a (non-empty) path from *act* to *act'*. Then, *act'* happens after *act*.

Contract Consistency

Contract consistency ensures that contracts are used after they have been created and before they are consumed.

Definition contract consistency A ledger is **consistent for a contract c** if all of the following holds for all actions act on c :

1. either act is itself **Create c** or a **Create c** happens before act
2. act does not happen before any **Create c** action
3. act does not happen after any **Exercise** action consuming c .

The consistency condition rules out the double spend example. As the red path below indicates, the second exercise in the example happens after a consuming exercise on the same contract, violating the contract consistency criteria.

In addition to the consistency notions, the before-after relation on actions can also be used to define the notion of **contract state** at any point in a given transaction. The contract state is changed by creating the contract and by exercising it consumingly. At any point in a transaction, we can then define the latest state change in the obvious way. Then, given a point in a transaction, the contract state of c is:

1. **active**, if the latest state change of c was a create;
2. **archived**, if the latest state change of c was a consuming exercise;
3. **inexistent**, if c never changed state.

A ledger is consistent for c exactly if **Exercise** and **Fetch** actions on c happen only when c is active, and **Create** actions only when c is inexistent. The figures below visualize the state of different contracts at all points in the example ledger.

The notion of order can be defined on all the different ledger structures: actions, transactions, lists of transactions, and ledgers. Thus, the notions of consistency, inputs and outputs, and contract state can also all be defined on all these structures. The **active contract set** of a ledger is the set of all contracts that are active on the ledger. For the example above, it consists of contracts *lou Bank P* and *PaintAgree P A*.

Fig. 7: Activeness of the *PaintOffer* contract

Fig. 8: Activeness of the *lou Bank A* contract

Key Consistency

Contract keys introduce a key uniqueness constraint for the ledger. To capture this notion, the contract model must specify for every contract in the system whether the contract has a key and, if so, the key. Every contract can have at most one key.

Like contracts, every key has a state. An action *act* is an **action on a key** *k* if

act is a **Create**, **Exercise**, or a **Fetch** action on a contract *c* with key *k*, or
act is the key assertion **NoSuchKey** *k*.

Definition key state The **key state** of a key on a ledger is determined by the last action *act* on the key:

If *act* is a **Create**, non-consuming **Exercise**, or **Fetch** action on a contract *c*, then the key state is **assigned** to *c*.

If *act* is a consuming **Exercise** action or a **NoSuchKey** assertion, then the key state is **free**.

If there is no such action *act*, then the key state is **unknown**.

A key is **unassigned** if its key state is either **free** or **unknown**.

Key consistency ensures that there is at most one active contract for each key and that all key assertions are satisfied.

Definition key consistency A ledger is **consistent for a key** *k* if for every action *act* on *k*, the key state *s* before *act* satisfies

If *act* is a **Create** action or **NoSuchKey** assertion, then *s* is **free** or **unknown**.

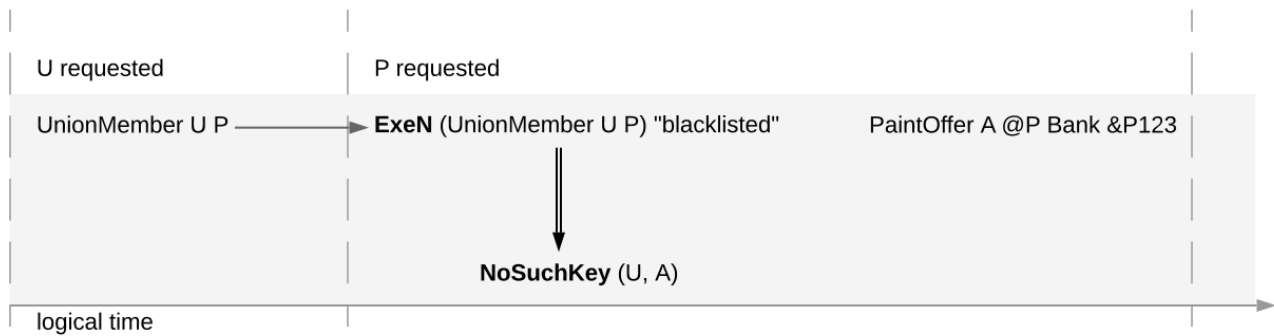

If *act* is an **Exercise** or **Fetch** action on some contract *c*, then *s* is **assigned** to *c* or **unknown**.

Key consistency rules out the problematic examples around key consistency. For example, suppose that the painter *P* has made a paint offer to *A* with reference number *P123*, but *A* has not yet accepted it. When *P* tries to create another paint offer to *David* with the same reference number *P123*, then this creation action would violate key uniqueness. The following ledger violates key uniqueness for the key (*P*, *P123*).

P requested	P requested
PaintOffer A @P Bank &P123	PaintOffer David @P Bank &P123

Key assertions can be used in workflows to evidence the inexistence of a certain kind of contract. For example, suppose that the painter *P* is a member of the union of painters *U*. This union maintains a blacklist of potential customers that its members must not do business with. A customer *A* is considered to be on the blacklist if there is an active contract *Blacklist* @*U* &*A*. To make sure that the painter *P* does not make a paint offer if *A* is blacklisted, the painter combines its commit with a **No-SuchKey** assertion on the key (*U*, *A*). The following ledger shows the transaction, where *UnionMember U P* represents *P*'s membership in the union *U*. It grants *P* the choice to perform such an assertion, which is needed for [authorization](#).

Key consistency extends to actions, transactions and lists of transactions just like the other consistency notions.

Ledger Consistency

Definition ledger consistency A ledger is **consistent** if it is consistent for all contracts and for all keys.

Internal Consistency

The above consistency requirement is too strong for actions and transactions in isolation. For example, the acceptance transaction from the paint offer example is not consistent as a ledger, because *PaintOffer A P Bank* and the *lou Bank A* contracts are used without being created before:

However, the transaction can still be appended to a ledger that creates these contracts and yields a consistent ledger. Such transactions are said to be internally consistent, and contracts such as the *PaintOffer A P Bank P123* and *lou Bank A* are called input contracts of the transaction. Dually, output contracts of a transaction are the contracts that a transaction creates and does not archive.

Definition internal consistency for a contract A transaction is **internally consistent for a contract c** if the following holds for all of its subactions act on the contract c

1. act does not happen before any **Create c** action
2. act does not happen after any exercise consuming c.

A transaction is **internally consistent** if it is internally consistent for all contracts and consistent for all keys.

Definition input contract For an internally consistent transaction, a contract c is an **input contract** of the transaction if the transaction contains an **Exercise** or a **Fetch** action on c but not a **Create c** action.

Definition output contract For an internally consistent transaction, a contract *c* is an **output contract** of the transaction if the transaction contains a **Create c** action, but not a consuming **Exercise** action on *c*.

Note that the input and output contracts are undefined for transactions that are not internally consistent. The image below shows some examples of internally consistent and inconsistent transactions.

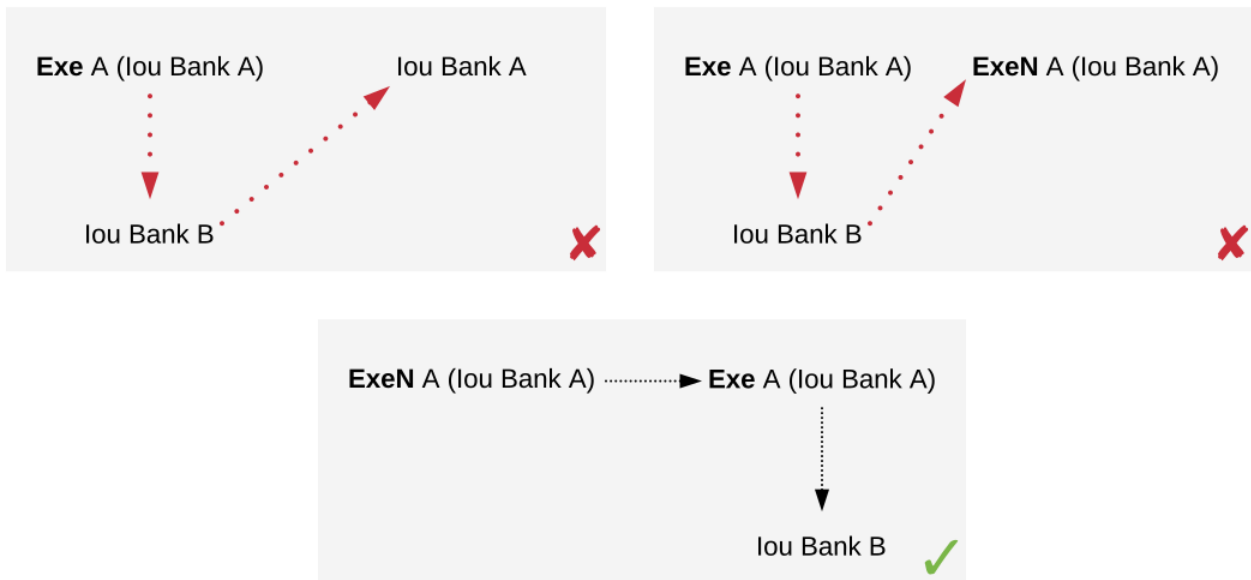

Fig. 9: The first two transactions violate the conditions of internal consistency. The first transaction creates the *lou* after exercising it consumingly, violating both conditions. The second transaction contains a (non-consuming) exercise on the *lou* after a consuming one, violating the second condition. The last transaction is internally consistent.

Similar to input contracts, we define the input keys as the set that must be unassigned at the beginning of a transaction.

Definition input key A key *k* is an **input key** to an internally consistent transaction if the first action act on *k* is either a **Create** action or a **NoSuchKey** assertion.

In the *blacklisting example*, *P*'s transaction has two input keys: (*U*, *A*) due to the **NoSuchKey** action and (*P*, *P123*) as it creates a *PaintOffer* contract.

46.1.2.3 Conformance

The *conformance* condition constrains the actions that may occur on the ledger. This is done by considering a **contract model** *M* (or a **model** for short), which specifies the set of all possible actions. A ledger is **conformant to M** (or conforms to *M*) if all top-level actions on the ledger are members of *M*. Like consistency, the notion of conformance does not depend on the requesters of a commit, so it can also be applied to transactions and lists of transactions.

For example, the set of allowed actions on IOU contracts could be described as follows.

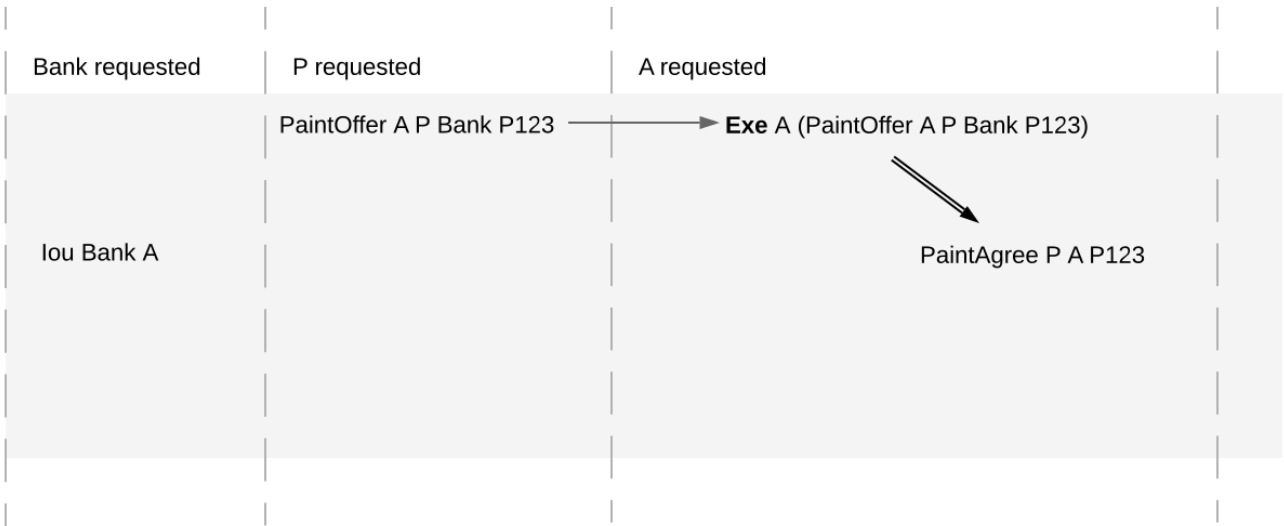

The boxes in the image are templates in the sense that the contract parameters in a box (such as obligor or owner) can be instantiated by arbitrary values of the appropriate type. To facilitate understanding, each box includes a label describing the intuitive purpose of the corresponding set of actions. As the image suggests, the transfer box imposes the constraint that the bank must remain the same both in the exercised IOU contract, and in the newly created IOU contract. However, the owner can change arbitrarily. In contrast, in the settle actions, both the bank and the owner must remain the same. Furthermore, to be conformant, the actor of a transfer action must be the same as the owner of the contract.

Of course, the constraints on the relationship between the parameters can be arbitrarily complex, and cannot conveniently be reproduced in this graphical representation. This is the role of Daml – it provides a much more convenient way of representing contract models. The link between Daml and contract models is explained in more detail in a [later section](#).

To see the conformance criterion in action, assume that the contract model allows only the following actions on *PaintOffer* and *PaintAgree* contracts.

The problem with the example where Alice changes the offer's outcome to avoid transferring the money now becomes apparent.

A’s commit is not conformant to the contract model, as the model does not contain the top-level action she is trying to commit.

46.1.2.4 Authorization

The last criterion rules out the last two problematic examples, *an obligation imposed on a painter*, and *the painter stealing Alice’s money*. The first of those is visualized below.

The reason why the example is intuitively impermissible is that the *PaintAgree* contract is supposed to express that the painter has an obligation to paint Alice’s house, but he never agreed to that obligation. On paper contracts, obligations are expressed in the body of the contract, and imposed on the contract’s *signatories*.

Signatories, Agreements, and Maintainers

To capture these elements of real-world contracts, the **contract model** additionally specifies, for each contract in the system:

- 1. A non-empty set of **signatories**, the parties bound by the contract.
- 2. An optional **agreement text** associated with the contract, specifying the off-ledger, real-world obligations of the signatories.
- 3. If the contract is associated with a key, a non-empty set of **maintainers**, the parties that make sure that at most one unconsumed contract exists for the key. The maintainers must be a subset of the signatories and depend only on the key. This dependence is captured by the function *maintainers* that takes a key and returns the key’s maintainers.

In the example, the contract model specifies that

1. an *lou obligor owner* contract has only the *obligor* as a signatory, and no agreement text.
2. a *MustPay obligor owner* contract has both the *obligor* and the *owner* as signatories, with an agreement text requiring the obligor to pay the owner a certain amount, off the ledger.
3. a *PaintOffer houseOwner painter obligor refNo* contract has only the painter as the signatory, with no agreement text. Its associated key consists of the painter and the reference number. The painter is the maintainer.
4. a *PaintAgree houseOwner painter refNo* contract has both the house owner and the painter as signatories, with an agreement text requiring the painter to paint the house. The key consists of the painter and the reference number. The painter is the only maintainer.

In the graphical representation below, signatories of a contract are indicated with a dollar sign (as a mnemonic for an obligation) and use a bold font. Maintainers are marked with @ (as a mnemonic who enforces uniqueness). Since maintainers are always signatories, parties marked with @ are implicitly signatories. For example, annotating the paint offer acceptance action with signatories yields the image below.

Authorization Rules

Signatories allow one to precisely state that the painter has an obligation. The imposed obligation is intuitively invalid because the painter did not agree to this obligation. In other words, the painter did not **authorize** the creation of the obligation.

In a Daml ledger, a party can **authorize** a subaction of a commit in either of the following ways:

Every top-level action of the commit is authorized by all requesters of the commit.

Every consequence of an exercise action act on a contract *c* is authorized by all signatories of *c* and all actors of act.

The second authorization rule encodes the offer-acceptance pattern, which is a prerequisite for contract formation in contract law. The contract *c* is effectively an offer by its signatories who act as offerers. The exercise is an acceptance of the offer by the actors who are the offerees. The consequences of the exercise can be interpreted as the contract body so the authorization rules of Daml ledgers closely model the rules for contract formation in contract law.

A commit is **well-authorized** if every subaction act of the commit is authorized by at least all of the **required authorizers** of act, where:

1. the required authorizers of a **Create** action on a contract *c* are the signatories of *c*.
2. the required authorizers of an **Exercise** or a **Fetch** action are its actors.
3. the required authorizers of a **NoSuchKey** assertion are the maintainers of the key.

We lift this notion to ledgers, whereby a ledger is well-authorized exactly when all of its commits are.

Examples

An intuition for how the authorization definitions work is most easily developed by looking at some examples. The main example, the paint offer ledger, is intuitively legitimate. It should therefore also be well-authorized according to our definitions, which it is indeed.

In the visualizations below, ✓ act denotes that the parties authorize the action act. The resulting authorizations are shown below.

In the first commit, the bank authorizes the creation of the IOU by requesting that commit. As the bank is the sole signatory on the IOU contract, this commit is well-authorized. Similarly, in the second commit, the painter authorizes the creation of the paint offer contract, and painter is the only signatory on that contract, making this commit also well-authorized.

The third commit is more complicated. First, Alice authorizes the exercise on the paint offer by requesting it. She is the only actor on this exercise, so this complies with the authorization requirement. Since the painter is the signatory of the paint offer, and Alice the actor of the exercise, they jointly authorize all consequences of the exercise. The first consequence is an exercise on the IOU, with Alice as the actor, so this is permissible. The second consequence is the creation of the new IOU (for P) by exercising the old IOU (for A). As the IOU was formerly signed by the bank, with Alice as the actor of the exercise, they jointly authorize this creation. This action is permissible as the bank is the sole signatory. The final consequence is creating the paint agreement with Alice and the painter as signatories. Since they both authorize the action, this is also permissible. Thus, the entire third commit is also well-authorized, and so is the ledger.

Similarly, the intuitively problematic examples are prohibited by our authorization criterion. In the first example, Alice forced the painter to paint her house. The authorizations for the example are shown below.

Alice authorizes the **Create** action on the *PaintAgree* contract by requesting it. However, the painter is also a signatory on the *PaintAgree* contract, but he did not authorize the **Create** action. Thus, this ledger is indeed not well-authorized.

In the second example, the painter steals money from Alice.

The bank authorizes the creation of the IOU by requesting this action. Similarly, the painter authorizes the exercise that transfers the IOU to him. However, the actor of this exercise is Alice, who has not authorized the exercise. Thus, this ledger is not well-authorized.

The rationale for making the maintainers required authorizers for a **NoSuchKey** assertion is discussed in the next section about [privacy](#).

46.1.2.5 Valid Ledgers, Obligations, Offers and Rights

Daml ledgers are designed to mimic real-world interactions between parties, which are governed by contract law. The validity conditions on the ledgers, and the information contained in contract models have several subtle links to the concepts of the contract law that are worth pointing out.

First, in addition to the explicit off-ledger obligations specified in the agreement text, contracts also specify implicit **on-ledger obligations**, which result from consequences of the exercises on contracts. For example, the *PaintOffer* contains an on-ledger obligation for A to transfer her IOU in case she accepts the offer. Agreement texts are therefore only necessary to specify obligations that are not already modeled as permissible actions on the ledger. For example, P's obligation to paint the house cannot be sensibly modeled on the ledger, and must thus be specified by the agreement text.

Second, every contract on a Daml ledger can simultaneously model both:

- a real-world offer, whose consequences (both on- and off-ledger) are specified by the **Exercise** actions on the contract allowed by the contract model, and
- a real-world contract proper, specified through the contract's (optional) agreement text.

Third, in Daml ledgers, as in the real world, one person's rights are another person's obligations. For example, A's right to accept the *PaintOffer* is P's obligation to paint her house in case she accepts. In Daml ledgers, a party's rights according to a contract model are the exercise actions the party can perform according to the authorization and conformance rules.

Finally, validity conditions ensure three important properties of the Daml ledger model, that mimic the contract law.

1. **Obligations need consent.** Daml ledgers follow the offer-acceptance pattern of the contract law, and thus ensures that all ledger contracts are formed voluntarily. For example, the following ledger is not valid.

2. **Consent is needed to take away on-ledger rights.** As only **Exercise** actions consume contracts, the rights cannot be taken away from the actors; the contract model specifies exactly who the actors are, and the authorization rules require them to approve the contract consumption. In the examples, Alice had the right to transfer her IOUs; painter's attempt to take that right away from her, by performing a transfer himself, was not valid.

Parties can still **delegate** their rights to other parties. For example, assume that Alice, instead of accepting painter's offer, decides to make him a counteroffer instead. The painter can then accept this counteroffer, with the consequences as before:

Here, by creating the *CounterOffer* contract, Alice delegates her right to transfer the IOU contract to the painter. In case of delegation, prior to submission, the requester must get informed about the contracts that are part of the requested transaction, but where the requester is not a signatory. In the example above, the painter must learn about the existence of the IOU for Alice before he can request the acceptance of the *CounterOffer*. The concepts of observers and divulgence, introduced in the next section, enable such scenarios.

3. **On-ledger obligations cannot be unilaterally escaped.** Once an obligation is recorded on a Daml ledger, it can only be removed in accordance with the contract model. For example, assuming the IOU contract model shown earlier, if the ledger records the creation of a *MustPay* contract, the bank cannot later simply record an action that consumes this contract:

...	Bank commits
...	Exe Bank (MustPay Bank A)
MustPay Bank A	

That is, this ledger is invalid, as the action above is not conformant to the contract model.

46.1.3 Causality and Local Daml Ledgers

Daml ledgers do not totally order all transactions. So different parties may observe two transactions on different Participant Nodes in different orders via the [Ledger API](#). Moreover, different Participant Nodes may output two transactions for the same party in different orders. This document explains the ordering guarantees that Daml ledgers do provide, by [example](#) and formally via the concept of [causality graphs](#) and [local ledgers](#).

The presentation assumes that you are familiar with the following concepts:

The [Ledger API](#)

The [Daml Ledger Model](#)

46.1.3.1 Causality Examples

A Daml Ledger need not totally order all transaction, unlike ledgers in the Daml Ledger Model. The following examples illustrate these ordering guarantees of the Ledger API. They are based on the paint counteroffer workflow from the Daml Ledger Model's [privacy section](#), ignoring the total ordering coming from the Daml Ledger Model. Recall that the *party projections* are as follows.

Stakeholders of a Contract See Creation and Archival in the Same Order

Every Daml Ledger orders the creation of the *CounterOffer A P Bank* before the painter exercising the consuming choice on the *CounterOffer*. (If the **Create** was ordered after the **Exercise**, the resulting shared ledger would be inconsistent, which violates the validity guarantee of Daml ledgers.) Accordingly, Alice will see the creation before the archival on her transaction stream and so will the painter. This does not depend on whether they are hosted on the same Participant Node.

Signatories of a Contract and Stakeholder Actors See Usages After the Creation and Before the Archival

The *Fetch A (lou Bank A)* action comes after the creation of the *lou Bank A* and before its archival, for both Alice and the Bank, because the Bank is a signatory of the *lou Bank A* contract and Alice is a stakeholder of the *lou Bank A* contract and an actor on the **Fetch** action.

Commits Are Atomic

Alice sees the **Create** of her *lou* before the creation of the *CounterOffer*, because the *CounterOffer* is created in the same commit as the **Fetch** of the *lou* and the **Fetch** commit comes after the **Create** of the *lou*.

Non-Consuming Usages in Different Commits May Appear in Different Orders

Suppose that the Bank exercises a non-consuming choice on the *lou Bank A* without consequences while Alice creates the *CounterOffer*. In the ledger shown below, the Bank's commit comes before Alice's commit.

The Bank's projection contains the nonconsuming **Exercise** and the **Fetch** action on the *lou*. Yet, the **Fetch** may come before the non-consuming **Exercise** in the Bank's transaction tree stream.

Out-of-Band Causality Is Not Respected

The following examples assume that Alice splits up her commit into two as follows:

Fig. 10: Counteroffer workflow with four commits.

Alice can specify in the *CounterOffer* the *lou* that she wants to pay the painter with. In a deployed implementation, Alice's application first observes the created *lou* contract via the transaction service or active contract service before she requests to create the *CounterOffer*. Such application logic does not induce an ordering between commits. So the creation of the *CounterOffer* need not come after the creation of the *lou*.

If Alice is hosted on several Participant Nodes, the Participant Nodes can therefore output the two creations in either order.

The rationale for this behaviour is that Alice could have learnt about the contract ID out of band or made it up. The Participant Nodes therefore cannot know whether there will ever be a **Create** event for the contract. So if Participant Nodes delayed outputting the **Create** action for the *CounterOffer* until a **Create** event for the *lou* contract was published, this delay might last forever and liveness is lost. Daml ledgers therefore do not capture data flow through applications.

Divulged Actions Do Not Induce Order

The painter witnesses the fetching of Alice's *lou* when the *Showlou* contract is consumed. The painter also witnesses the **Exercise** of the *lou* when Alice exercises the transfer choice as a consequence of the painter accepting the *CounterOffer*. However, as the painter is not a stakeholder of Alice's *lou* contract, he may observe Alice's *Showlou* commit after the archival of the *lou* as part of accepting the *CounterOffer*.

In practice, this can happen in a setup where two Participant Nodes N_1 and N_2 host the painter. He sees the divulged *lou* and the created *CounterOffer* through N_1 's transaction tree stream and then submits the acceptance through N_1 . Like in the previous example, N_2 does not know about the dependence of the two commits. Accordingly, N_2 may output the accepting transaction *before* the *Showlou* contract on the transaction stream.

Even though this may seem unexpected, it is in line with stakeholder-based ledgers: Since the painter is not a stakeholder of the *lou* contract, he should not care about the archival or creates of the contract. In fact, the divulged *lou* contract shows up neither in the painter's active contract service nor in the flat transaction stream. Such witnessed events are included in the transaction tree

stream as a convenience: They relieve the painter from computing the consequences of the choice and enable him to check that the action conforms to the Daml model.

Similarly, being an actor of an **Exercise** action induces order with respect to other uses of the contract only if the actor is a contract stakeholder. This is because non-stakeholder actors of an **Exercise** action merely authorize the action, but they do not track whether the contract is active; this is what signatories and contract observers are for. Analogously, choice observers of an **Exercise** action benefit from the ordering guarantees only if they are contract stakeholders.

The Ordering Guarantees Depend on the Party

By the previous example, for the painter, fetching the *lou* is not ordered before transferring the *lou*. For Alice, however, the **Fetch** must appear before the **Exercise** because Alice is a stakeholder on the *lou* contract. This shows that the ordering guarantees depend on the party.

46.1.3.2 Causality Graphs

The above examples indicate that Daml ledgers order transactions only partially. Daml ledgers can be represented as finite directed acyclic graphs (DAG) of transactions.

Definition causality graph A **causality graph** is a finite directed acyclic graph G of transactions that is transitively closed. Transitively closed means that whenever $v_1 \rightarrow v_2$ and $v_2 \rightarrow v_3$ are edges in G , then there is also an edge $v_1 \rightarrow v_3$ in G .

Definition action order For a causality graph G , the induced **action order** on the actions in the transactions combines the graph-induced order between transactions with the execution order of actions inside each transaction. It is the least partial order that includes the following ordering relations between two actions act_1 and act_2 :

- act_1 and act_2 belong to the same transaction and act_1 precedes act_2 in the transaction.
- act_1 and act_2 belong to different transactions in vertices tx_1 and tx_2 and there is a path in G from tx_1 to tx_2 .

Note: Checking for an edge instead of a path in G from tx_1 to tx_2 is equivalent because causality graphs are transitively closed. The definition uses *path* because the figures below omit transitive edges for readability.

The action order is a partial order on the actions in a causality graph. For example, the following diagram shows such a causality graph for the ledger in the above [Out-of-band causality example](#). Each grey box represents one transaction and the graph edges are the solid arrows between the boxes. Diagrams omit transitive edges for readability; in this graph the edge from $tx1$ to $tx4$ is not shown. The **Create** action of Alice's *lou* is ordered before the **Create** action of the *Showlou* contract because there is an edge from the transaction $tx1$ with the *lou* **Create** to the transaction $tx3$ with the *Showlou* **Create**. Moreover, the *Showlou* **Create** action is ordered before the **Fetch** of Alice's *lou* because the **Create** action precedes the **Fetch** action in the transaction. In contrast, the **Create** actions of the *CounterOffer* and Alice's *lou* are unordered: neither precedes the other because they belong to different transaction and there is no directed path between them.

Fig. 11: Causality graph for the [counteroffer workflow with four commits](#).

Consistency

Consistency ensures that a causality graph sufficiently orders all the transactions. It generalizes [ledger consistency](#) from the Daml Ledger Model as [explained below](#).

Definition Causal consistency for a contract Let G be a causality graph and X be a set of actions on a contract c that belong to transactions in G . The graph G is **causally consistent for the contract c** on X if all of the following hold:

If X is not empty, then X contains exactly one **Create** action. This action precedes all other actions in X in G 's action order.

If X contains a consuming **Exercise** action act , then act follows all actions in X other than act in G 's action order.

Definition Causal consistency for a key Let G be a causality graph and X be a set of actions on a key k that belong to transactions in G . The graph G is **causally consistent for the key k** on X if all of the following hold:

All **Create** and consuming **Exercise** actions in X are totally ordered in G 's action order and **Creates** and consuming **Exercises** alternate, starting with **Create**. Every consecutive **Create-Exercise** pair acts on the same contract.

All **NoSuchKey** actions in X are action-ordered with respect to all **Create** and consuming **Exercise** actions in X . No **NoSuchKey** action is action-ordered between a **Create** action and its subsequent consuming **Exercise** action in X .

Definition Consistency for a causality graph Let X be a subset of the actions in a causality graph G . Then G is **consistent** on X (or **X-consistent**) if G is causally consistent for all contracts c on the set of actions on c in X and for all keys k on the set of actions on k in X . G is **consistent** if G is consistent on all the actions in G .

When edges are added to an X -consistent causality graph such that it remains acyclic and transitively closed, the resulting graph is again X -consistent. So it makes sense to consider minimal consistent causality graphs.

Definition Minimal consistent causality graph An X -consistent causality graph G is **X-minimal** if no strict subgraph of G (same vertices, fewer edges) is an X -consistent causality graph. If X is the set of all actions in G , then X is omitted.

For example, the [above causality graph for the split counteroffer workflow](#) is consistent. This causality graph is minimal, as the following analysis shows:

Edge	Justification
tx1 -> tx3	Alice's <i>lou</i> Create action of must precede the Fetch action.
tx2 -> tx4	The <i>CounterOffer</i> Create action of must precede the Exercise action.
tx3 -> tx4	The consuming Exercise action on Alice's <i>lou</i> must follow the Fetch action.

We can focus on parts of the causality graph by restricting the set X . If X consists of the actions on *lou* contracts, this causality graph is X -consistent. Yet, it is not X -minimal since the edge tx2 -> tx4 can be removed without violating X -consistency: the edge is required only because of the *CounterOffer* actions, which are excluded from X . The X -minimal consistent causality graph looks as follows, where the actions in X are highlighted in red.

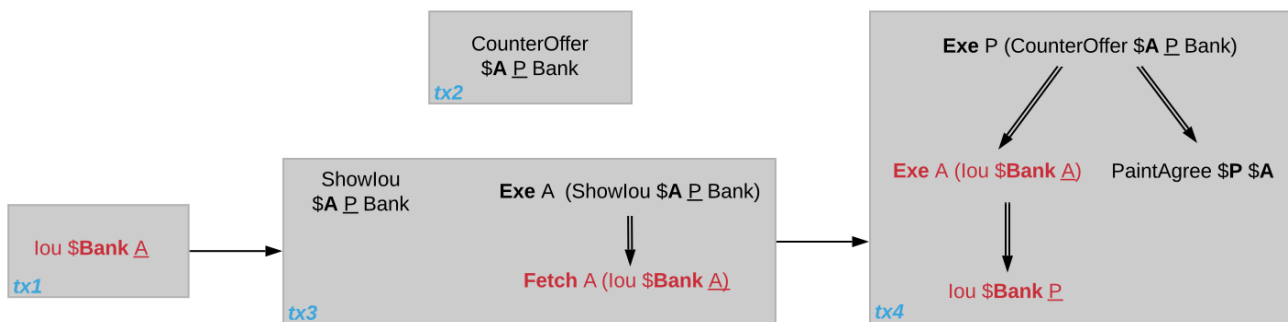

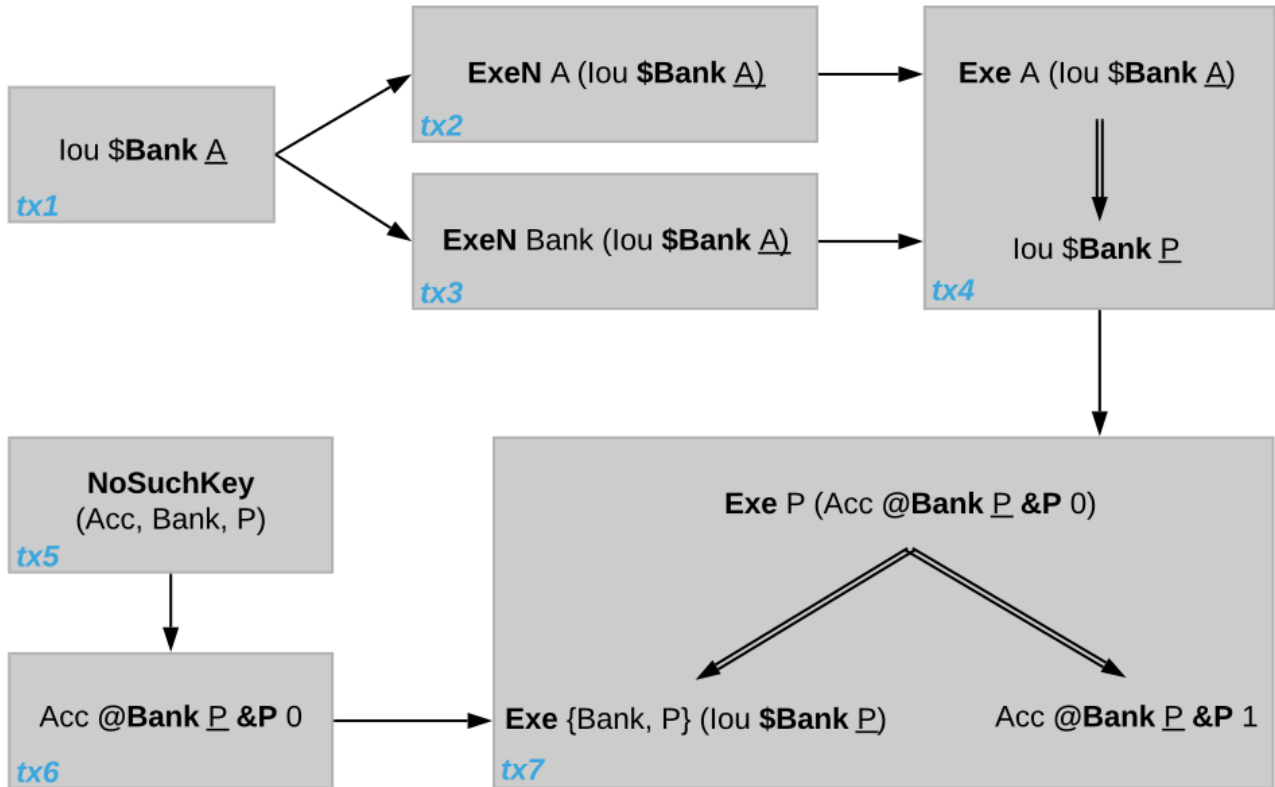

Fig. 12: Minimal consistent causality graph for the highlighted actions.

Another example of a minimal causality graph is shown below. At the top, the transactions tx1 to tx4 create an *lou* for Alice, exercise two non-consuming choices on it, and transfer the *lou* to the painter. At the bottom, tx5 asserts that there is no key for an Account contract for the painter. Then, tx6 creates an such account with balance 0 and tx7 deposits the painter's *lou* from tx4 into the account, updating the balance to 1.

Unlike in a linearly ordered ledger, the causality graph relates the transactions of the *lou* transfer workflow with the Account creation workflow only at the end, when the *lou* is deposited into the account. As will be formalized below, the Bank, Alice, and the painter therefore need not observe the transactions tx1 to tx7 in the same order.

Moreover, transaction tx2 and tx3 are unordered in this causality graph even though they act on the same *lou* contract. However, as both actions are non-consuming, they do not interfere with each other and could therefore be parallelized, too. Alice and the Bank accordingly may observe them in different orders.

The **NoSuchKey** action in tx5 must be ordered with respect to the two Account **Create** actions in tx6 and tx7 and the consuming **Exercise** on the Account contract in tx7, by the key consistency conditions. For this set of transactions, consistency allows only one such order: tx5 comes before tx6 because tx7 is atomic: tx5 cannot be interleaved with tx7, e.g., between the consuming **Exercise** of the *Acc Bank P P 0* and the **Create** of the updated account *Acc Bank P P 1*.

NoSuchKey actions are similar to non-consuming **Exercises** and **Fetches** of contracts when it comes to causal ordering: If there were another transaction tx5' with a **NoSuchKey** (Acc, Bank, P) action, then tx5 and tx5' need not be ordered, just like tx2 and tx3 are unordered.

From Causality Graphs to Ledgers

Since causality graphs are acyclic, their vertices can be sorted topologically and the resulting list is again a causality graph, where every vertex has an outgoing edge to all later vertices. If the original causality graph is X-consistent, then so is the topological sort, as topological sorting merely adds edges. For example, the transactions on the [ledger](#) in the [out-of-band causality example](#) are a topological sort of the [corresponding causality graph](#).

Conversely, we can reduce an X-consistent causality graph to only the causal dependencies that X-consistency imposes. This gives a minimal X-consistent causality graph.

Definition Reduction of a consistent causality graph For an X-consistent causality graph G , there exists a unique minimal X-consistent causality graph $\text{reduce}_X(G)$ with the same vertices and the edges being a subset of G . The graph $\text{reduce}_X(G)$ is called the X-**reduction** of G . As before, X is omitted if it contains all actions in G .

The causality graph for the split `CounterOffer` workflow is minimal and therefore its own reduction. It is also the reduction of the topological sort, i.e., the [ledger](#) in the [out-of-band causality example](#).

Note: The reduction $\text{reduce}_X(G)$ of an X-consistent causality graph G can be computed as follows:

1. Set the vertices of G' to the vertices of G .
 2. The causal consistency conditions for contracts and keys demand that certain pairs of actions act_1 and act_2 in X must be action-ordered. For each such pair, determine the actions' ordering in G and add an edge to G' from the earlier action's transaction to the later action's transaction.
 3. $\text{reduce}_X(G)$ is the transitive closure of G' .
-

Topological sort and reduction link causality graphs G to the ledgers L from the Daml Ledger Model. Topological sort transforms a causality graph G into a sequence of transactions; extending them with the requesters gives a sequence of commits, i.e., a ledger in the Daml Ledger Model. Conversely, a sequence of commits L yields a causality graph G_L by taking the transactions as vertices and adding an edge from tx_1 to tx_2 whenever tx_1 's commit precedes tx_2 's commit in the sequence.

There are now two consistency definitions:

[Ledger Consistency](#) according to Daml Ledger Model
[Consistency of causality graph](#)

Fortunately, the two definitions are equivalent: If G is a consistent causality graph, then the topological sort is ledger consistent. Conversely, if the sequence of commits L is ledger consistent, G_L is a consistent causality graph, and so is the reduction $\text{reduce}(G_L)$.

46.1.3.3 Local Ledgers

As explained in the Daml Ledger Model, parties see only a [projection](#) of the shared ledger for privacy reasons. Like consistency, projection extends to causality graphs as follows.

Definition Stakeholder informee A party P is a **stakeholder informee** of an action act if all of the following holds:

- P is an informee of act .
- If act is an action on a contract then P is a stakeholder of the contract.

An **Exercise** and **Fetch** action acts on the input contract, a **Create** action on the created contract, and a **NoSuchKey** action does not act on a contract. So for a **NoSuchKey** action, the stakeholder informees are the key maintainers.

Definition Causal consistency for a party A causality graph G is **consistent for a party** P (P -consistent) if G is consistent on all the actions that P is a stakeholder informee of.

The notions of X -minimality and X -reduction extend to parties accordingly.

For example, the [split counteroffer causality graph without the edge \$tx2 \rightarrow tx4\$](#) is consistent for the Bank because the Bank is a stakeholder informee of exactly the highlighted actions. It is also minimal Bank-consistent and the Bank-reduction of the [original split counteroffer causality graph](#).

Definition Projection of a consistent causality graph The **projection** $proj_P(G)$ of a consistent causality graph G to a party P is the P -reduction of the following causality graph G' :

The vertices of G' are the vertices of G projected to P , excluding empty projections.

There is an edge between two vertices v_1 and v_2 in G' if there is an edge from the G -vertex corresponding to v_1 to the G -vertex corresponding to v_2 .

For the [split counteroffer causality graph](#), the projections to Alice, the Bank, and the painter are as follows.

Fig. 13: Projections of the [split counteroffer causality graph](#).

Alice's projection is the same as the original minimal causality graph. The Bank sees only actions on *lou* contracts, so the causality graph projection does not contain *tx2* any more. Similarly, the painter is not aware of *tx1*, where Alice's *lou* is created. Moreover, there is no longer an edge from *tx3* to *tx4* in

the painter's local ledger. This is because the edge is induced by the **Fetch** of Alice's *lou* preceding the consuming **Exercise**. However, the painter is not an informee of those two actions; he merely witnesses the **Fetch** and **Exercise** actions as part of divulgence. Therefore no ordering is required from the painter's point of view. This difference explains the [divulgence causality example](#).

Ledger API Ordering Guarantees

The [Transaction Service](#) provides the updates as a stream of Daml transactions and the [Active Contract Service](#) summarizes all the updates up to a given point by the contracts that are active at this point. Conceptually, both services are derived from the local ledger that the Participant Node manages for each hosted party. That is, the transaction tree stream for a party is a topological sort of the party's local ledger. The flat transaction stream contains precisely the `CreatedEvents` and `ArchivedEvents` that correspond to **Create** and consuming **Exercise** actions in transaction trees on the transaction tree stream where the party is a stakeholder of the affected contract.

Note: The transaction trees of the [Transaction Service](#) omit **Fetch** and **NoSuchKey** actions that are part of the transactions in the local ledger. The **Fetch** and **NoSuchKey** actions are thus removed before the [Transaction Service](#) outputs the transaction trees.

Similarly, the active contract service provides the set of contracts that are active at the returned offset according to the Transaction Service streams. That is, the contract state changes of all events from the transaction event stream are taken into account in the provided set of contracts. In particular, an application can process all subsequent events from the flat transaction stream or the transaction tree stream without having to take events before the snapshot into account.

Since the topological sort of a local ledger is not unique, different Participant Nodes may pick different orders for the transaction streams of the same party. Similarly, the transaction streams for different parties may order common transactions differently, as the party's local ledgers impose different ordering constraints. Nevertheless, Daml ledgers ensure that all local ledgers are projections of a virtual shared causality graph that connects to the Daml Ledger Model as described above. The ledger validity guarantees therefore extend via the local ledgers to the Ledger API. These guarantees are subject to the deployed Daml ledger's trust assumptions.

Note: The virtual shared causality graph exists only as a concept, to reason about Daml ledger guarantees. A deployed Daml ledger in general does not store or even construct such a shared causality graph. The Participant Nodes merely maintain the local ledgers for their parties. They synchronize these local ledgers to the extent that they remain consistent. That is, all the local ledgers can in theory be combined into a consistent single causality graph of which they are projections.

Explaining the Causality Examples

The *causality examples* can be explained in terms of causality graphs and local ledgers as follows:

1. *Stakeholders of a Contract See Creation and Archival in the Same Order* Causal consistency for the contract requires that the **Create** comes before the consuming **Exercise** action on the contract. As all stakeholders are informees on **Create** and consuming **Exercise** actions of their contracts, the stakeholder's local ledgers impose this order on the actions.
2. *Signatories of a Contract and Stakeholder Actors See Usages After the Creation and Before the Archival* Causal consistency for the contract requires that the **Create** comes before the non-consuming **Exercise** and **Fetch** actions of a contract and that consuming **Exercises** follow them. Since signatories and stakeholder actors are informees of **Create**, **Exercise**, and **Fetch** actions, the stakeholder's local ledgers impose this order on the actions.
3. *Commits Are Atomic* Local ledgers are DAGs of (projected) transactions. Topologically sorting such a DAG cannot interleave one transaction with another, even if the transaction consists of several top-level actions.
4. *Non-Consuming Usages in Different Commits May Appear in Different Orders* Causal consistency does not require ordering between non-consuming usages of a contract. As there is no other action in the transaction that would prescribe an ordering, the Participant Nodes can output them in any order.
5. *Out-of-Band Causality Is Not Respected* Out-of-band data flow is not captured by causal consistency and therefore does not induce ordering.
6. *Divulged Actions Do Not Induce Order* The painter is not an informee of the **Fetch** and **Exercise** actions on Alice's *lou*; he merely witnesses them. The *painter's local ledger* therefore does not order tx3 before tx4. So the painter's transaction stream can output tx4 before tx3.
7. *The Ordering Guarantees Depend on the Party* Alice is an informee of the **Fetch** and **Exercise** actions on her *lou*. Unlike for the painter, *her local ledger* does order tx3 before tx4, so Alice is guaranteed to observe tx3 before tx4 on all Participant Nodes through which she is connect to the Daml ledger.

46.1.4 Privacy

The previous sections have addressed two out of three questions posed in the introduction: what the ledger looks like , and who may request which changes . This section addresses the last one, who sees which changes and data . That is, it explains the privacy model for Daml ledgers.

The privacy model of Daml Ledgers is based on a **need-to-know basis**, and provides privacy **on the level of subtransactions**. Namely, a party learns only those parts of ledger changes that affect contracts in which the party has a stake, and the consequences of those changes. And maintainers see all changes to the contract keys they maintain.

To make this more precise, a stakeholder concept is needed.

46.1.4.1 Contract Observers and Stakeholders

Intuitively, as signatories are bound by a contract, they have a stake in it. Actors might not be bound by the contract, but they still have a stake in their actions, as these are the actor's rights. Generalizing this, **observers** are parties who might not be bound by the contract, but still have the right to see the contract. For example, Alice should be an observer of the *PaintOffer*, such that she is made aware that the offer exists.

Signatories are already determined by the contract model discussed so far. The full **contract model** additionally specifies the **contract observers** on each contract. A **stakeholder** of a contract (according to a given contract model) is then either a signatory or a contract observer on the contract. Note that in Daml, as detailed [later](#), controllers specified using simple syntax are automatically made contract observers whenever possible.

In the graphical representation of the paint offer acceptance below, contract observers who are not signatories are indicated by an underline.

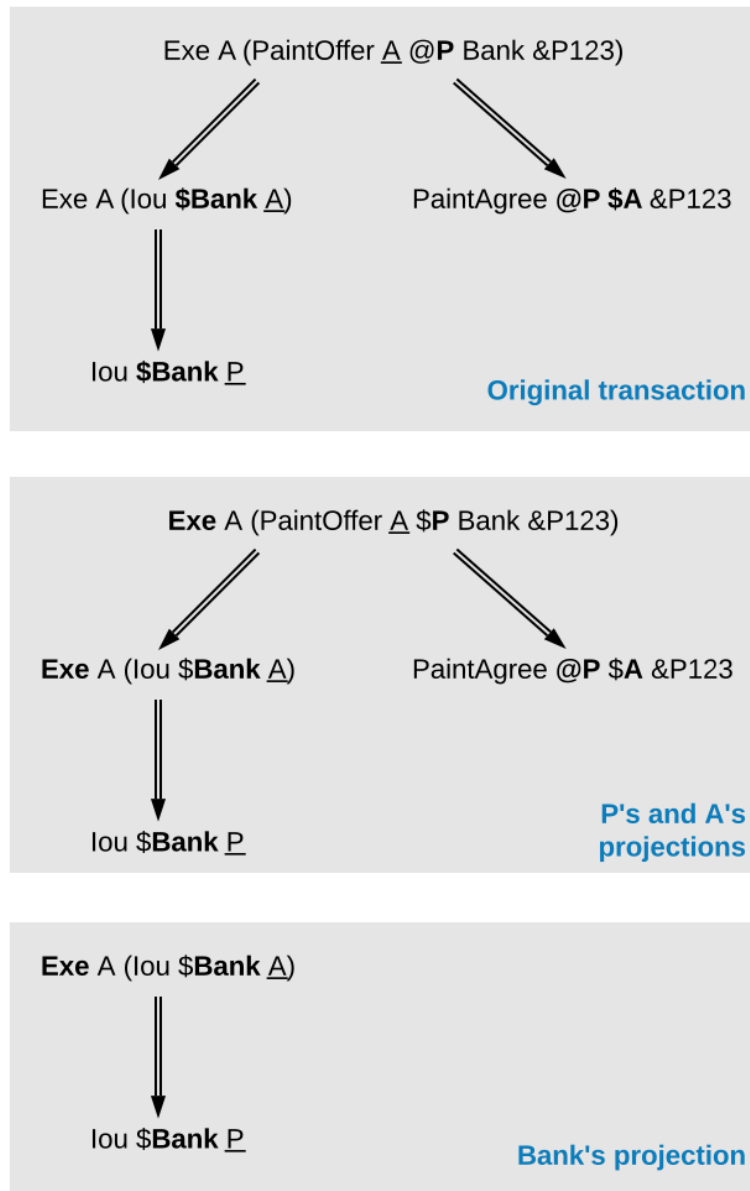

46.1.4.2 Choice Observers

In addition to contract observers, the contract model can also specify **choice observers** on individual **Exercise** actions. Choice observers get to see a specific exercise on a contract, and to view its consequences. Choice observers are not considered stakeholders of the contract, they only affect the set of informees on an action, for the purposes of projection (see below).

46.1.4.3 Projections

Stakeholders should see changes to contracts they hold a stake in, but that does not mean that they have to see the entirety of any transaction that their contract is involved in. This is made precise through *projections* of a transaction, which define the view that each party gets on a transaction. Intuitively, given a transaction within a commit, a party will see only the subtransaction consisting of all actions on contracts where the party is a stakeholder. Thus, privacy is obtained on the subtransaction level.

An example is given below. The transaction that consists only of Alice's acceptance of the *PaintOffer* is projected for each of the three parties in the example: the painter, Alice, and the bank.

Since both the painter and Alice are stakeholders of the *PaintOffer* contract, the exercise on this contract is kept in the projection of both parties. Recall that consequences of an exercise action are a part of the action. Thus, both parties also see the exercise on the *lou Bank A* contract, and the creations of the *lou Bank P* and *PaintAgree* contracts.

The bank is *not* a stakeholder on the *PaintOffer* contract (even though it is mentioned in the contract). Thus, the projection for the bank is obtained by projecting the consequences of the exercise on the *PaintOffer*. The bank is a stakeholder in the contract *lou Bank A*, so the exercise on this contract is kept in the bank's projection. Lastly, as the bank is not a stakeholder of the *PaintAgree* contract, the corresponding **Create** action is dropped from the bank's projection.

Note the privacy implications of the bank's projection. While the bank learns that a transfer has occurred from A to P, the bank does *not* learn anything about *why* the transfer occurred. In practice, this means that the bank does not learn what A is paying for, providing privacy to A and P with respect to the bank.

As a design choice, Daml Ledgers show to contract observers only the *state changing* actions on the contract. More precisely, **Fetch** and non-consuming **Exercise** actions are not shown to contract ob-

servers - except when they are also actors or choice observers of these actions. This motivates the following definition: a party p is an **informee** of an action A if one of the following holds:

- A is a **Create** on a contract c and p is a stakeholder of c .
- A is a consuming **Exercise** on a contract c , and p is a stakeholder of c or an actor on A . Note that a Daml choice controller *can be an exercise actor without being a contract stakeholder*.
- A is a non-consuming **Exercise** on a contract c , and p is a signatory of c or an actor on A .
- A is an **Exercise** action and p is a choice observer on A .
- A is a **Fetch** on a contract c , and p is a signatory of c or an actor on A .
- A is a **NoSuchKey** k assertion and p is a maintainer of k .

Then, we can formally define the **projection** of a transaction $tx = act_1, \dots, act_n$ for a party p is the sub-transaction obtained by doing the following for each action act_i :

1. If p is an informee of act_i , keep act_i as-is.
2. Else, if act_i has consequences, replace act_i by the projection (for p) of its consequences, which might be empty.
3. Else, drop act_i .

Finally, the **projection of a ledger** l for a party p is a list of transactions obtained by first projecting the transaction of each commit in l for p , and then removing all empty transactions from the result. Note that the projection of a ledger is not a ledger, but a list of transactions. Projecting the ledger of our complete paint offer example yields the following projections for each party:

Examine each party's projection in turn:

1. The painter does not see any part of the first commit, as he is not a stakeholder of the *lou Bank A* contract. Thus, this transaction is not present in the projection for the painter at all. However, the painter is a stakeholder in the *PaintOffer*, so he sees both the creation and the exercise of this contract (again, recall that all consequences of an exercise action are a part of the action

itself).

2. Alice is a stakeholder in both the *lou Bank A* and *PaintOffer A B Bank* contracts. As all top-level actions in the ledger are performed on one of these two contracts, Alice's projection includes all the transactions from the ledger intact.
3. The Bank is only a stakeholder of the IOU contracts. Thus, the bank sees the first commit's transaction as-is. The second commit's transaction is, however dropped from the bank's projection. The projection of the last commit's transaction is as described above.

Ledger projections do not always satisfy the definition of consistency, even if the ledger does. For example, in *P*'s view, *lou Bank A* is exercised without ever being created, and thus without being made active. Furthermore, projections can in general be non-conformant. However, the projection for a party *p* is always

internally consistent for all contracts,
consistent for all contracts on which *p* is a stakeholder, and
consistent for the keys that *p* is a maintainer of.

In other words, *p* is never a stakeholder on any input contracts of its projection. Furthermore, if the contract model is **subaction-closed**, which means that for every action *act* in the model, all subactions of *act* are also in the model, then the projection is guaranteed to be conformant. As we will see shortly, Daml-based contract models are conformant. Lastly, as projections carry no information about the requesters, we cannot talk about authorization on the level of projections.

46.1.4.4 Privacy Through Authorization

Setting the maintainers as required authorizers for a **NoSuchKey** assertion ensures that parties cannot learn about the existence of a contract without having a right to know about their existence. So we use authorization to impose *access controls* that ensure confidentiality about the existence of contracts. For example, suppose now that for a *PaintAgreement* contract, both signatories are key maintainers, not only the painter. That is, we consider *PaintAgreement @A @P &P123* instead of *PaintAgreement \$A @P &P123*. Then, when the painter's competitor *Q* passes by *A*'s house and sees that the house desperately needs painting, *Q* would like to know whether there is any point in spending marketing efforts and making a paint offer to *A*. Without key authorization, *Q* could test whether a ledger implementation accepts the action **NoSuchKey** (*A*, *P*, *refNo*) for different guesses of the reference number *refNo*. In particular, if the ledger does not accept the transaction for some *refNo*, then *Q* knows that *P* has some business with *A* and his chances of *A* accepting his offer are lower. Key authorization prevents this flow of information because the ledger always rejects *Q*'s action for violating the authorization rules.

For these access controls, it suffices if one maintainer authorizes a **NoSuchKey** assertion. However, we demand that *all* maintainers must authorize it. This is to prevent spam in the projection of the maintainers. If only one maintainer sufficed to authorize a key assertion, then a valid ledger could contain **NoSuchKey** *k* assertions where the maintainers of *k* include, apart from the requester, arbitrary other parties. Unlike **Create** actions to contract observers, such assertions are of no value to the other parties. Since processing such assertions may be expensive, they can be considered spam. Requiring all maintainers to authorize a **NoSuchKey** assertion avoids the problem.

46.1.4.5 Divulgence: When Non-Stakeholders See Contracts

The guiding principle for the privacy model of Daml ledgers is that contracts should only be shown to their stakeholders. However, ledger projections can cause contracts to become visible to other parties as well.

In the example of *ledger projections of the paint offer*, the exercise on the *PaintOffer* is visible to both the painter and Alice. As a consequence, the exercise on the *lou Bank A* is visible to the painter, and the creation of *lou Bank P* is visible to Alice. As actions also contain the contracts they act on, *lou Bank A* was thus shown to the painter and *lou Bank P* was shown to Alice.

Showing contracts to non-stakeholders through ledger projections is called **divulgence**. Divulgence is a deliberate choice in the design of Daml ledgers. In the paint offer example, the only proper way to accept the offer is to transfer the money from Alice to the painter. Conceptually, at the instant where the offer is accepted, its stakeholders also gain a temporary stake in the actions on the two *lou* contracts, even though they are never recorded as stakeholders in the contract model. Thus, they are allowed to see these actions through the projections.

More precisely, every action *act* on *c* is shown to all informees of all ancestor actions of *act*. These informees are called the **witnesses** of *act*. If one of the witnesses *W* is not a stakeholder on *c*, then *act* and *c* are said to be **divulged** to *W*. Note that only **Exercise** actions can be ancestors of other actions.

Divulgence can be used to enable delegation. For example, consider the scenario where Alice makes a counteroffer to the painter. Painter's acceptance entails transferring the IOU to him. To be able to construct the acceptance transaction, the painter first needs to learn about the details of the IOU that will be transferred to him. To give him these details, Alice can fetch the IOU in a context visible to the painter:

In the example, the context is provided by consuming a *Showlou* contract on which the painter is a stakeholder. This now requires an additional contract type, compared to the original paint offer example. An alternative approach to enable this workflow, without increasing the number of contracts required, is to replace the original *lou* contract by one on which the painter is a contract observer. This would require extending the contract model with a (consuming) exercise action on the *lou* that creates a new *lou*, with observers of Alice's choice. In addition to the different number of commits, the two approaches differ in one more aspect. Unlike stakeholders, parties who see contracts only through divulgence have no guarantees about the state of the contracts in question. For example, consider what happens if we extend our (original) paint offer example such that the painter immediately settles the IOU.

While Alice sees the creation of the *lou Bank P* contract, she does not see the settlement action. Thus, she does not know whether the contract is still active at any point after its creation. Similarly, in the previous example with the counteroffer, Alice could spend the IOU that she showed to the painter by the time the painter attempts to accept her counteroffer. In this case, the painter's transaction could not be added to the ledger, as it would result in a double spend and violate validity. But the painter has no way to predict whether his acceptance can be added to the ledger or not.

46.1.5 Daml: Define Contract Models Compactly

As described in preceding sections, both the integrity and privacy notions depend on a contract model, and such a model must specify:

1. a set of allowed actions on the contracts, and
2. the signatories, contract observers, and
3. an optional agreement text associated with each contract, and
4. the optional key associated with each contract and its maintainers.

The sets of allowed actions can in general be infinite. For instance, the actions in the IOU contract model considered earlier can be instantiated for an arbitrary obligor and an arbitrary owner. As enumerating all possible actions from an infinite set is infeasible, a more compact way of representing models is needed.

Daml provides exactly that: a compact representation of a contract model. Intuitively, the allowed actions are:

1. **Create** actions on all instances of templates such that the template arguments satisfy the *ensure* clause of the template
2. **Exercise** actions on a contract corresponding to choices on that template, with given choice arguments, such that:
 1. The actors match the controllers of the choice. That is, the controllers define the *required authorizers* of the choice.
 2. The choice observers match the observers annotated in the choice.
 3. The exercise kind matches.
 4. All assertions in the update block hold for the given choice arguments.
 5. Create, exercise, fetch and key statements in the update block are represented as create, exercise and fetch actions and key assertions in the consequences of the exercise action.
3. **Fetch** actions on a contract corresponding to a *fetch* of that instance inside of an update block. The actors must be a non-empty subset of the contract stakeholders. The actors are determined dynamically as follows: if the fetch appears in an update block of a choice *ch* on a contract *c1*, and the fetched contract ID resolves to a contract *c2*, then the actors are defined as the intersection of (1) the signatories of *c1* union the controllers of *ch* with (2) the stakeholders of *c2*.
A *fetchByKey* statement also produces a **Fetch** action with the actors determined in the same way. A *lookupByKey* statement that finds a contract also translates into a **Fetch** action, but all maintainers of the key are the actors.
4. **NoSuchKey** assertions corresponding to a *lookupByKey* update statement for the given key that does not find a contract.

An instance of a Daml template, that is, a **Daml contract**, is a triple of:

1. a contract identifier
2. the template identifier
3. the template arguments

The signatories of a Daml contract are derived from the template arguments and the explicit signatory annotations on the contract template. The contract observers are those explicitly defined in the template using the `observer` keyword.

For example, the following template exactly describes the contract model of a simple IOU with a unit amount, shown earlier.

```
template MustPay with
  obligor : Party
  owner : Party
where
  signatory obligor, owner
  agreement
    show obligor <> " must pay " <>
    show owner <> " one unit of value"

template Iou with
  obligor : Party
  owner : Party
where
  signatory obligor
  observer owner

  choice Transfer
    : ContractId Iou
    with newOwner : Party
    controller owner
    do create Iou with obligor; owner = newOwner

  choice Settle
    : ContractId MustPay
    controller owner
    do create MustPay with obligor; owner
```

In this example, the owner is specified as an observer, since it must be able to see the contract to exercise the `Transfer` and `Settle` choices on it.

The template identifiers of contracts are created through a content-addressing scheme. This means every contract is self-describing in a sense: it constrains its stakeholder annotations and all Daml-conformant actions on itself. As a consequence, one can talk about the Daml contract model, as a single contract model encoding all possible instances of all possible templates. This model is subaction-closed; all exercise and create actions done within an update block are also always permissible as top-level actions.

46.1.6 Exceptions

The introduction of exceptions, a new Daml feature, has many implications for the ledger model. This page describes the changes to the ledger model introduced as part of this new feature.

46.1.6.1 Structure

Under the new feature, Daml programs can raise and catch exceptions. When an exception is caught in a `catch` block, the subtransaction starting at the corresponding `try` block is rolled back.

To support this in our ledger model, we need to modify the transaction structure to indicate which subtransactions were rolled back. We do this by introducing **rollback nodes** in the transaction. Each rollback node contains a rolled back subtransaction. Rollback nodes are not considered ledger actions.

Therefore we define transactions as a list of **nodes**, where each node is either a ledger action or a rollback node. This is reflected in the updated EBNF grammar for the transaction structure:

```

Transaction ::= Node*
Node        ::= Action | Rollback
Rollback    ::= 'Rollback' Transaction
Action      ::= 'Create' contract
              | 'Exercise' party* contract Kind Transaction
              | 'Fetch' party* contract
              | 'NoSuchKey' key
Kind        ::= 'Consuming' | 'NonConsuming'

```

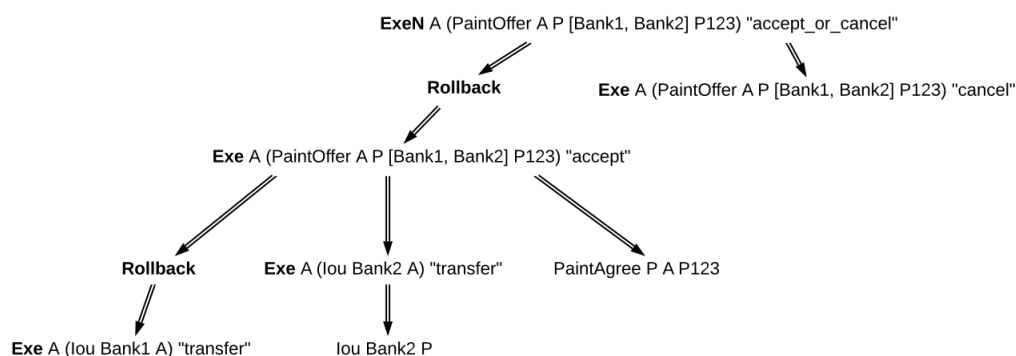

Note that *Action* and *Kind* have the same definition as before, but since *Transaction* may now contain rollback nodes, this means that an *Exercise* action may have a rollback node as one of its consequences.

For example, the following transaction contains a rollback node inside an exercise. It represents a paint offer involving multiple banks. The painter P is offering to paint A's house as long as they receive an lou from Bank1 or, failing that, from Bank2. When A accepts, they confirm that transfer of an lou via Bank1 has failed for some reason, so they roll it back and proceed with a transfer via Bank2:

Note also that rollback nodes may be nested, which represents a situation where multiple exceptions are raised and caught within the same transaction.

For example, the following transaction contains the previous one under a rollback node. It represents a case where the `accept` has failed at the last moment, for some reason, and a `cancel` exercise has been issued in response.

46.1.6.2 Consistency

In the previous section on [consistency](#), we defined a `before-after` relation on ledger actions. This notion needs to be revised in the presence of rollback nodes. It is no longer enough to perform a preorder traversal of the transaction tree, because the actions under a rollback node cannot affect actions that appear later in the transaction tree.

For example, a contract may be consumed by an exercise under a rollback node, and immediately again after the rollback node. This is allowed because the exercise was rolled back, and this does not represent a `double spend` of the same contract. You can see this in the nested example above, where the `PaintOffer` contract is consumed by an `agree` exercise, which is rolled back, and then by a `cancel` exercise.

So, we now define the `before-after` relation as a partial order, rather than a total order, on all the actions of a transaction. This relation is defined as follows: `act1` comes before `act2` (equivalently, `act2` comes after `act1`) if and only if `act1` appears before `act2` in a preorder traversal of the transaction tree, and any rollback nodes that are ancestors of `act1` are also ancestors of `act2`.

With this modified `before-after` relation, the notion of internal consistency remains the same. Meaning that, for example, for any contract `c`, we still forbid the creation of `c` coming after any action on `c`, and we forbid any action on `c` coming after a consuming exercise on `c`.

In the example above, neither consuming exercise comes after the other. They are part of separate continuities, so they don't introduce inconsistency. Here are three continuities implied by the `before-after` relation. The first:

The second:

And the third:

As you can see, in each of these continuities, no contract was consumed twice.

46.1.6.3 Transaction Normalization

The same before-after relation can be represented in more than one way using rollback nodes. For example, the following three transactions have the same before-after relation among their ledger actions (act1, act2, and act3):

Because of this, these three transactions are equivalent. More generally, two transactions are equivalent if:

The transactions are the same when you ignore all rollback nodes. That is, if you remove every rollback node and absorb its children into its parent, then two transactions are the same. Equivalently, the transactions have the same ledger actions with the same preorder traversal and subaction relation.

The transactions have the same before-after relation between their actions.

The transactions have the same set of rollback children. A rollback child is an action whose direct parent is a rollback node.

For all three transactions above, the transaction tree ignoring rollbacks consists only of top-level actions (act1, act2, and act3), the before-after relation only says that act2 comes before act3, and all three actions are rollback children. Thus all three transactions are equivalent.

Transaction normalization is the process by which equivalent transactions are converted into the same transaction. In the case above, all three transactions become the transaction in the middle when normalized.

To normalize a transaction, we apply three rules repeatedly across the whole transaction:

1. If a rollback node is empty, we drop it.
2. If a rollback node starts with another rollback node, for instance:

```
'Rollback' [ 'Rollback' tx , node1, ..., nodeN ]
```

Then we re-associate the rollback nodes, bringing the inner rollback node out:

```
'Rollback' tx, 'Rollback' [ node1, ..., nodeN ]
```

3. If a rollback node ends with another rollback node, for instance:

```
'Rollback' [ node1, ..., nodeN, 'Rollback' [ node1', ..., nodeM' ] ]
```

Then we flatten the inner rollback node into its parent:

```
'Rollback' [ node1, ..., nodeN, node1', ..., nodeM' ]
```

In the example above, using rule 3 we can turn the left transaction into the middle transaction, and using rule 2 we can turn the right transaction into the middle transaction. None of these rules apply to the middle transaction, so it is already normalized.

In the end, a normalized transaction cannot contain any rollback node that starts or ends with another rollback node, nor may it contain any empty rollback nodes. The normalization process minimizes the number of rollback nodes and their depth needed to represent the transaction.

To reduce the potential for information leaks, the ledger model must only contain normalized transactions. This also applies to projected transactions. An unnormalized transaction is always invalid.

46.1.6.4 Authorization

Since they are not ledger actions, rollback nodes do not have authorizers directly. Instead, a ledger is well-authorized exactly when the same ledger with rollback nodes removed (that is, replacing the rollback nodes with their children) is well-authorized, according to [the old definition](#).

This is captured in the following rules:

When a rollback node is authorized by p , then all of its children are authorized by p . In particular:

- Top-level rollback nodes share the authorization of the requestors of the commit with all of its children.
- Rollback nodes that are a consequence of an exercise action act on a contract c share the authorization of the signatories of c and the actors of act with all of its children.
- A nested rollback node shares the authorization it got from its parent with all of its children.

The required authorizers of a rollback node are the union of all the required authorizers of its children.

46.1.6.5 Privacy

Rollback nodes also have an interesting effect on the notion of privacy in the ledger model. When projecting a transaction for a party p , it's necessary to preserve some of the rollback structure of the transaction, even if p does not have the right to observe every action under it. For example, we need p to be able to verify that a rolled back exercise (to which they are an informee) is conformant, but we also need p to know that the exercise was rolled back.

We adjust the definition of projection as follows:

1. For a ledger action, the projection for p is the same as it was before. That is, if p is an informee of the action, then the entire subtree is preserved. Otherwise the action is dropped, and the action's consequences are projected for p .
2. For a rollback node, the projection for p consists of the projection for p of its children, wrapped up in a new rollback node. In other words, projection happens under the rollback node, but the node is preserved.

After applying this process, the transaction must be normalized.

Consider the deeply nested example from before. To calculate the projection for Bank1, we note that the only visible action is the bottom left exercise. Removing the actions that Bank1 isn't an informee of, this results in a transaction containing a rollback node, containing a rollback node, containing an exercise. After normalization, this becomes a simple rollback node containing an exercise. See below:

The privacy section of the ledger model makes a point of saying that a contract model should be **subaction-closed** to support projections. But this requirement is not necessarily true once we in-

roduce rollbacks. Rollback nodes may contain actions that are not valid as standalone actions, since they may have been interrupted prematurely by an exception.

Instead, we require that the contract model be **projection-closed**, i.e. closed under projections for any party 'p'. This is a weaker requirement that matches what we actually need.

46.1.6.6 Relation to Daml Exceptions

Rollback nodes are created when an exception is thrown and caught within the same transaction. In particular, any exception that is caught within a try-catch will generate a rollback node if there are any ledger actions to roll back. For example:

```
try do
  cid <- create MyContract { ... }
  exercise cid MyChoice { ... }
  throw MyException
catch
  MyException ->
    create MyOtherContract { ... }
```

This Daml code will try to create a contract, and exercise a choice on this contract, before throwing an exception. That exception is caught immediately, and then another contract is created.

Thus a rollback node is created, to reset the ledger to the state it had at the start of the `try` block. The rollback node contains the create and exercise nodes. After the rollback node, another contract is created. Thus the final transaction looks like this:

Note that rollback nodes are only created if an exception is *caught*. An uncaught exception will result in an error, not a transaction.

After execution of the Daml code, the generated transaction is normalized.

46.1.7 Identity and Package Management

Since Daml ledgers enable parties to automate the management of their rights and obligations through smart contract code, they also have to provide party and code management functions. Hence, this document addresses:

1. Management of parties' digital identifiers in a Daml ledger.
2. Distribution of smart contract code between the parties connected to the same Daml ledger.

The access to this functionality is usually more restricted compared to the other Ledger API services, as they are part of the administrative API. This document is intended for the users and implementers of this API.

The administrative part of the Ledger API provides both a [party management service](#) and a [package service](#). Any implementation of the party and package services is guaranteed to accept inputs and provide outputs of the format specified by these services. However, the services' *behavior* – the relationship between the inputs and outputs that the various parties observe – is largely implementation dependent. The remainder of the document will present:

1. The minimal behavioral guarantees for identity and package services across all ledger implementations. The service users can rely on these guarantees, and the implementers must ensure that they hold.
2. Guidelines for service users, explaining how different ledgers handle the unspecified part of the behavior.

46.1.7.1 Identity Management

A Daml ledger may freely define its own format of party and participant node identifiers, with some minor constraints on the identifiers' serialized form. For example, a ledger may use human-readable strings as identifiers, such as `Alice` or `Alice's Bank`. A different ledger might use public keys as identifiers, or the keys' fingerprints. The applications should thus not rely on the format of the identifier – even a software upgrade of a Daml ledger may introduce a new format.

By definition, identifiers identify parties, and are thus unique for a ledger. They do not, however, have to be unique across different ledgers. That is, two identical identifiers in two different ledgers do not necessarily identify the same real-world party. Moreover, a real-world entity can have multiple identifiers (and thus parties) within the same ledger.

Since the identifiers might be difficult to interpret and manage for humans, the ledger may also accompany each identifier with a user-friendly **display name**. Unlike the identifier, the display name is not guaranteed to be unique, and two different participant nodes might return different display names for the same party identifier. Furthermore, a display name is in general not guaranteed to have any link to real world identities. For example, a party with a display name `Attorney of Nigerian Prince` might well be controlled by a real-world entity without a bar exam. However, particular ledger deployments might make stronger guarantees about this link. Finally, the association of identifiers to display names may change over time. For example, a party might change its display name from `Bruce` to `Caitlyn` – as long as the identifier remains the same, so does the party.

Provisioning Identifiers

The set of parties of any Daml ledger is dynamic: new parties may always be added to the system. The first step in adding a new party to the ledger is to provision a new identifier for the party. The Ledger API provides an [AllocateParty](#) method for this purpose. The method, if successful, returns a new party identifier. The `AllocateParty` call can take the desired identifier and display name as optional parameters, but these are merely hints and the ledger implementation may completely ignore them.

If the call returns a new identifier, the participant node serving this call is ready to host the party with this identifier. For some ledgers (Daml for VMware Blockchain in particular), the returned identifier is guaranteed to be **unique** in the ledger; namely, no other call of the `AllocateParty` method at this or any other ledger participant may return the same identifier. On Canton ledgers, the identifier is also unique as long as the participant node is configured correctly (in particular, it does not share its private key with other participant nodes).

After an identifier is returned, the ledger is set up in such a way that the participant node serving the call is allowed to issue commands and receive transactions on behalf of the party. However, the newly provisioned identifier need not be visible to the other participant nodes. For example, consider the setup with two participants P1 and P2, where the party `Alice_123` is hosted on P1. Assume that a new party `Bob_456` is next successfully allocated on P2. As long as P1 and P2 are connected to the same Canton sync domain or Daml ledger, `Alice_123` can now submit a command with `Bob_456` as an informee.

For diagnostics, the ledger provides a [ListKnownParties](#) method which lists parties known to the participant node. The parties can be local (i.e., hosted by the participant) or not.

Identifiers and Authorization

To issue commands or receive transactions on behalf of a newly provisioned party, an application must provide a proof to the party's hosting participant that they are authorized to represent the party. Before the newly provisioned party can be used, the application will have to obtain a token for this party. The issuance of tokens is specific to each ledger and independent of the Ledger API. The same is true for the policy which the participants use to decide whether to accept a token.

To learn more about Ledger API security model, please read the [Authorization documentation](#).

Identifiers and the Real World

The `substrate` on which Daml workflows are built are the real-world obligations of the parties in the workflow. To give value to these obligations, they must be connected to parties in the real world. However, the process of linking party identifiers to real-world entities is left to the ledger implementation.

In centralized deployments, one can simplify the process by trusting the operator of the writer node(s) with providing the link to the real world. For example, if the operator is a stock exchange, it might guarantee that a real-world exchange participant whose legal name is `Bank Inc.` is represented by a ledger party with the identifier `Bank Inc.`. Alternatively, it might use a random identifier, but guarantee that the display name is `Bank Inc.`. In general, a ledger might not have such a single store of identities. The solutions for linking the identifiers to real-world identities could rely on certificate chains, [verifiable credentials](#), or other mechanisms. The mechanisms can be implemented off-ledger, using Daml workflows (for instance, a `know your customer` workflow), or a combination of these.

46.1.7.2 Package Management

All Daml ledgers implement endpoints that allow for provisioning new Daml code to the ledger. The vetting process for this code, however, depends on the particular ledger implementation and its configuration. The remainder of this section describes the endpoints and general principles behind the vetting process. The details of the process are ledger-dependent.

Package Formats and Identifiers

Any code – i.e., Daml templates – to be uploaded must be compiled down to the Daml-LF language. The unit of packaging for Daml-LF is the `.dalf` file. Each `.dalf` file is uniquely identified by its **package identifier**, which is the hash of its contents. Templates in a `.dalf` file can reference templates from other `.dalf` files, i.e., `.dalf` files can depend on other `.dalf` files. A `.dar` file is a simple archive containing multiple `.dalf` files, and has no identifier of its own. The archive provides a convenient way to package `.dalf` files together with their dependencies. The Ledger API supports only `.dar` file uploads. Internally, the ledger implementation need not (and often will not) store the uploaded `.dar` files, but only the contained `.dalf` files.

Package Management API

The package management API supports two methods:

[`UploadDarFile`](#) for uploading `.dar` files. The ledger implementation is, however, free to reject any and all packages and return an error. Furthermore, even if the method call succeeds, the ledger's vetting process might restrict the usability of the template. For example, assume that Alice successfully uploads a `.dar` file to her participant containing a `NewTemplate` template. It may happen that she can now issue commands that create `NewTemplate` instances with Bob as a stakeholder, but that all commands that create `NewTemplate` instances with Charlie as a stakeholder fail.

[`ListKnownPackages`](#) that lists the `.dalf` package vetted for usage at the participant node. Like with the previous method, the usability of the listed templates depends on the ledger's vetting process.

Package Vetting

Using a Daml package entails running its Daml code. The Daml interpreter ensures that the Daml code cannot interact with the environment of the system on which it is executing. However, the operators of the ledger infrastructure nodes may still wish to review and vet any Daml code before allowing it to execute. One reason for this is that the Daml interpreter currently lacks a notion of reproducible resource limits, and executing a Daml contract might result in high memory or CPU usage.

Thus, Daml ledgers generally allow some form of vetting a package before running its code on a node. Not all nodes in a Daml ledger must vet all packages, as it is possible that some of them will not execute the code. The exact vetting mechanism is ledger-dependent. For example, in the [Daml Sandbox](#), the vetting is implicit: uploading a package through the Ledger API already vets the package, since it's assumed that only the system administrator has access to these API facilities. The vetting process can be manual, where an administrator inspects each package, or it can be automated, for example, by accepting only packages with a digital signature from a trusted package issuer.

In Canton, participant nodes also only need to vet code for the contracts of the parties they host. As only participants execute contract code, only they need to vet it. The vetting results may also differ at different participants. For example, participants `P1` and `P2` might vet a package containing a `NewTemplate` template, whereas `P3` might reject it. In that case, if Alice is hosted at `P1`, she can create `NewTemplate` instances with stakeholder Bob who is hosted at `P2`, but not with stakeholder Charlie if he's hosted at `P3`.

Package Upgrades

The Ledger API does not have any special support for package upgrades. A new version of an existing package is treated the same as a completely new package, and undergoes the same vetting process. Upgrades to active contracts can be done by the Daml code of the new package version, by archiving the old contracts and creating new ones.

46.1.8 Time on Daml Ledgers

The Daml language contains a function `getTime` which returns the `current time`. However, the concept of a `current time` can be challenging in a distributed setting.

This document describes the detailed semantics of time on Daml ledgers, centered around the two timestamps assigned to each transaction: the *ledger time* `lt_TX` and the *record time* `rt_TX`.

46.1.8.1 Ledger Time

The *ledger time* `lt_TX` is a property of a transaction. It is a timestamp that defines the value of all `getTime` calls in the given transaction, and has microsecond resolution. The ledger time is assigned by the submitting participant as part of the Daml command interpretation.

46.1.8.2 Record Time

The *record time* `rt_TX` is another property of a transaction. It is a timestamp with microsecond resolution, and it is assigned by the backing storage mechanism when the transaction is persisted.

The record time should be an intuitive representation of `real time`, but the Daml abstract ledger model does not prescribe exactly how to assign the record time. Each persistence technology might use a different way of representing time in a distributed setting.

46.1.8.3 Guarantees

The ledger time of a valid transaction `TX` must fulfill the following rules:

1. **Causal monotonicity:** for any action (create, exercise, fetch, lookup) in `TX` on a contract `C`, $lt_TX \geq lt_C$, where `lt_C` is the ledger time of the transaction that created `C`.
2. **Bounded skew:** $rt_TX - skew_min \leq lt_TX \leq rt_TX + skew_max$, where `skew_min` and `skew_max` are parameters defined by the ledger.

Apart from that, no other guarantees are given on the ledger time. In particular, neither the ledger time nor the record time need to be monotonically increasing.

Time has therefore to be considered slightly fuzzy in Daml, with the fuzziness depending on the skew parameters. Daml applications should not interpret the value returned by `getTime` as a precise timestamp.

46.1.8.4 Ledger Time Model

The *ledger time model* is the set of parameters used in the assignment and validation of ledger time. It consists of the following:

1. `skew_min` and `skew_max`, the bounds on the difference between `lt_TX` and `rt_TX`.
2. `transaction_latency`, the average duration from the time a transaction is submitted from a participant to the ledger until the transaction is recorded. This value is used by the participant to account for latency when submitting transactions to the ledger: transactions are submitted slightly ahead of their ledger time, with the intention that they arrive at `lt_TX == rt_TX`.

The ledger time model is part of the ledger configuration and can be changed by ledger operators through the `SetTimeModel` config management API.

46.1.8.5 Assign Ledger Time

The ledger time is assigned automatically by the participant. In most cases, Daml applications will not need to worry about ledger time and record time at all.

For reference, this section describes the details of how the ledger time is currently assigned. The algorithm is not part of the definition of time in Daml, and may change in the future.

1. When submitting commands over the ledger API, users can optionally specify a `min_ledger_time_rel` or `min_ledger_time_abs` argument. This defines a lower bound for the ledger time in relative and absolute terms, respectively.
2. The ledger time is set to the highest of the following values:
 1. `max(lt_C_1, ..., lt_C_n)`, the maximum ledger time of all contracts used by the given transaction
 2. `t_p`, the local time on the participant
 3. `t_p + min_ledger_time_rel`, if `min_ledger_time_rel` is given
 4. `min_ledger_time_abs`, if `min_ledger_time_abs` is given
3. Since the set of commands used by a given transaction can depend on the chosen time, the above process might need to be repeated until a suitable ledger time is found.
4. If no suitable ledger time is found after 3 iterations, the submission is rejected. This can happen if there is contention around a contract, or if the transaction uses a very fine-grained control flow based on time.
5. At this point, the ledger time may lie in the future (e.g., if a large value for `min_ledger_time_rel` was given). The participant waits until `lt_TX - transaction_latency` before it submits the transaction to the ledger - the intention is that the transaction is recorded at `lt_TX == rt_TX`.

Use the parameters `min_ledger_time_rel` and `min_ledger_time_abs` if you expect that command interpretation will take a considerable amount of time, such that by the time the resulting transaction is submitted to the ledger, its assigned ledger time is not valid anymore. Note that these parameters can only make sure that the transaction arrives roughly at `rt_TX` at the ledger. If a subsequent validation on the ledger takes longer than `skew_max`, the transaction will still be rejected and you'll have to ask your ledger operator to increase the `skew_max` time model parameter.

46.1.9 The Smart Contract Upgrade Model in Depth

This document describes in detail what rules govern package validation upon upload and how contracts, choice arguments and choice results are upgraded or downgraded at runtime. These topics are for a large part covered in [Smart Contract Upgrade](#). This document acts as a thorough reference.

46.1.9.1 Static Checks

Upgrade static checks are performed once alongside other validity checks when a DAR is uploaded to a participant. DARs deemed invalid for upgrades are rejected.

DAR upgrade checks are broken down into package-level checks, which are in turn broken down into module, template and data type-level checks.

Packages

Definition: A *utility package* is a package with no template definition, no interface definition, no exception definition, and only non-[serializable](#) data type definitions. A utility package typically consists of helper functions and constants, but no type definitions.

In the following validity check, packages whose LF version does not support upgrades (1.15 and earlier) and utility packages are ignored.

A DAR is checked against previously uploaded DARs for upgrade validity on upload to a participant. Specifically, for every package with [name](#) p and [version](#) v present in the uploaded DAR:

1. The participant looks up versions v_{prev} and v_{next} of p in its package database, such that v_{prev} is the greatest version of p smaller than v , and v_{next} is the smallest version of p greater than v . Note that they may not always exist.

2. The participant checks that version v of p is a valid upgrade of version v_{prev} of p , if it exists.
3. The participant checks that version v_{next} of p is a valid upgrade of version v of p , if it exists.

Therefore being a valid upgrade for a DAR is context dependent: it depends on what packages are already uploaded on the participant. It also *modular*: checks are performed at the package level. That is, a new version of a package is rejected as soon as it contains some element which doesn't properly upgrade its counterpart in the old package, even if some other elements do. Similarly, all packages in a DAR must pass the check for the DAR to be accepted. If one of the packages fails the check, the entire DAR is rejected.

Modules

The modules of the new version of a package must form a superset of the modules of the prior version of that package. In other words, it is valid to add new modules but deleting a module leads to a validation error.

Examples

In the file tree below, package v2 is a potentially valid upgrade of package v1, assuming v2/A.daml is a valid upgrade of v1/A.daml.

In the file tree below, package v2 cannot possibly be a valid upgrade of v1 because it doesn't define module B.

Templates

The templates of the new version of a package must form a superset of the templates of the prior version of that package. In other words, it is valid to add new templates but deleting a template leads to a validation error.

Examples

Below, the module on the right is a valid upgrade of the module on the left. But the module on the left is **not** a valid upgrade of the module on the right because it lacks a definition for template T2.

<pre> module M where template T1 with p : Party where signatory p </pre>	<pre> module M where template T1 with p : Party where signatory p template T2 with p : Party where signatory p </pre>
---	---

Template Parameters

The new version of a template may add new optional parameters at the end of the parameter sequence of the prior version of the template. The types of the parameters that the new template has in common with the prior template must be pairwise valid upgrades of the original types.

Deleting a parameter leads to a validation error.

Adding a parameter in the middle of the parameter sequence leads to a validation error.

As a special case of the two points above, renaming a parameter leads to a validation error.

Adding a non-optional parameter at the end of the parameter leads to a validation error.

Examples

Below, the template on the right is a valid upgrade of the template on the left. It adds an optional parameter `x1` at the end of the parameter sequence.

<pre> template T with p : Party where signatory p </pre>	<pre> template T with p : Party x1 : Optional Int where signatory p </pre>
--	--

Below, the template on the right is **not** a valid upgrade of the template on the left because it adds a new parameter `x1` before `p` instead of adding it at the end of the parameter sequence.

<pre> template T with p : Party where signatory p </pre>	<pre> template T with x1 : Optional Int p : Party where signatory p </pre>
--	--

Below, the template on the right is **not** a valid upgrade of the template on the left because it drops parameter `x1`.

<pre>template T with p : Party x1 : Int where signatory p</pre>	<pre>template T with p : Party where signatory p</pre>
---	--

Below, the template on the right is **not** a valid upgrade of the template on the left because it changes the type of `x1` from `Int` to `Text`. `Text` is not a valid upgrade of `Int`.

<pre>template T with p : Party x1 : Int where signatory p</pre>	<pre>template T with p : Party x1 : Text where signatory p</pre>
---	--

Template Keys

The key of the new version of a template must be a valid upgrade of the prior version's key.

Adding or removing a key leads to a validation error.

Changing the key type to one that is not a valid upgrade of the original type leads to a validation error.

Examples

Below, the template on the right is a valid upgrade of the template on the left because the key type of the template on the right is a valid upgrade of the key type of the template on the left:

<pre>data MyKey = MyKey with p : Party template T with p : Party where signatory p key MyKey p : MyKey maintainer key.p</pre>	<pre>data MyKey = MyKey with p : Party i : Optional Int template T with p : Party where signatory p key MyKey p None : MyKey maintainer key.p</pre>
--	--

Below, the template on the right is **not** a valid upgrade of the template on the left because it adds a key.

```
template T
  with
    p : Party
    k : Text
  where
    signatory p
```

```
template T
  with
    p : Party
    k : Text
  where
    signatory p
    key (p, k) : (Party, Text)
    maintainer (fst key)
```

Below, the template on the right is **not** a valid upgrade of the template on the left because it deletes its key.

```
template T
  with
    p : Party
    k : Text
  where
    signatory p
    key (p, k) : (Party, Text)
    maintainer (fst key)
```

```
template T
  with
    p : Party
    k : Text
  where
    signatory p
```

Below, the template on the right is **not** a valid upgrade of the template on the left because it changes the key type for a type that is not a valid upgrade of `(Party, Text)`.

```
template T
  with
    p : Party
    k : Text
  where
    signatory p
    key (p, k) : (Party, Text)
    maintainer (fst key)
```

```
template T
  with
    p : Party
    k : Text
  where
    signatory p
    key (p, 2) : (Party, Int)
    maintainer (fst key)
```

Template Choices

The choices of the new version of a template must form a superset of the choices of the prior version of the template template. In other words, it is valid to add new choices but deleting a choice leads to a validation error.

Examples

Below, the template on the right is a valid upgrade of the template on the left. It adds a choice `C` to the previous version of the template. But the template on the left is **not** a valid upgrade of the template on the right as it deletes a choice.

<pre> template T with p : Party where signatory p </pre>	<pre> template T with p : Party where signatory p choice C : () controller p do return () </pre>
--	---

Template Choices - Parameters

As with template parameters, the new version of a choice may add new optional parameters at the end of the parameter sequence of the prior version of that choice. The types of the parameters that the new choice has in common with the prior choice must be pairwise valid upgrades of the original types.

Deleting a parameter leads to a validation error.

Adding a parameter in the middle of the parameter sequence leads to a validation error.

As a special case of the two points above, renaming a parameter leads to a validation error.

Adding a non-optional parameter at the end of the parameter sequence leads to a validation error.

Example

Below, the choice on the right is a valid upgrade of the choice on the left. It adds an optional parameter `x2` at the end of the parameter sequence.

<pre> choice C : () with x1 : Int controller p do return () </pre>	<pre> choice C : () with x1 : Int x2 : Optional Text controller p do return () </pre>
--	---

Below, the choice on the right is **not** a valid upgrade of the choice on the left because it adds a new parameter `x2` before `x1` instead of adding it at the end of the parameter sequence.

<pre> choice C : () with x1 : Int controller p do return () </pre>	<pre> choice C : () with x2 : Optional Text x1 : Int controller p do return () </pre>
--	---

Below, the choice on the right is **not** a valid upgrade of the choice on the left because it adds a new field `x2` before `x1` instead of adding it at the end of the parameter sequence.

<pre>choice C : () with x1 : Int controller p do return ()</pre>	<pre>choice C : () with x2 : Optional Text x1 : Int controller p do return ()</pre>
--	---

Below, the choice on the right is **not** a valid upgrade of the choice on the left because it drops parameter `x1`.

<pre>choice C : () with x1 : Int controller p do return ()</pre>	<pre>choice C : () with controller p do return ()</pre>
--	---

Below, the choice on the right is **not** a valid upgrade of the choice on the left because it changes the type of `x1` from `Int` to `Text`. `Text` is not a valid upgrade of `Int`.

<pre>choice C : () with x1 : Int controller p do return ()</pre>	<pre>choice C : () with controller p do return ()</pre>
--	---

Template Choices - Return Type

The return type of the new version of a choice must be a valid upgrade of the return type of the prior version of that choice.

Changing the return type of a choice for a non-valid upgrade leads to a validation error.

Examples

Below, the choice on the right is **not** a valid upgrade of the choice on the left because it changes its return type from `()` to `Int`. `Int` is not a valid upgrade of `()`.

```
choice C : ()
  controller p
  do
    return ()
```

```
choice C : Int
  controller p
  do
    return 1
```

Data Types

The serializable data types of the new version of a module must form a superset of the serializable data types of the prior version of that package. In other words, it is valid to add new data types but deleting a data type leads to a validation error.

Changing the variety of a serializable data type leads to a validation error. For instance, one cannot change a record type into a variant type.

Non-serializable data types are inexistent from the point of view of the upgrade validity check. Turning a non-serializable data type into a serializable one amounts to adding a new data type, which is valid. Turning a serializable data type into a non-serializable one amounts to deleting this data type, which is invalid.

Examples

Below, the module on the right is a valid upgrade of the module on the left. It defines an additional serializable data type B.

```
module M where

data A = A
```

```
module M where

data A = A
data B = B
```

Below, the module on the right is a valid upgrade of the module on the left. It turns the non-serializable type A into a serializable one. The non-serializable type is invisible to the upgrade validity check so this amounts to adding a new data type to the module on the right.

```
module M where

data A = A
  with
    x : Int -> Int
```

```
module M where

data A = A
  with
```

Below, the module on the right is **not** a valid upgrade of the module on the left because it changes the variety of A from record type to variant type.

```
module M where

data A = A
  with
```

```
module M where

data A = A | B
```

Below, the module on the right is **not** a valid upgrade of the module on the left because it drops the serializable data type `A`.

<pre>module M where data A = A</pre>	<pre>module M where</pre>
---------------------------------------	---------------------------

Below, the module on the right is **not** a valid upgrade of the module on the left because although it adds an optional field to the record type `A`, it also turns `A` into a non-serializable type, which amounts to deleting `A` from the point of view of the upgrade validity check.

<pre>module M where data A = A with</pre>	<pre>module M where data A = A with x : Optional (Int -> Int)</pre>
--	---

Data Types - Records

The new version of a record may add new optional fields at the end of the field sequence of the prior version of that record. The types of the fields that the new record has in common with the prior record must be pairwise valid upgrades of the original types.

Deleting a field leads to a validation error.

Adding a field in the middle of the field sequence leads to a validation error.

As a special case of the two points above, renaming a field leads to a validation error.

Adding a non-optional field at the end of the field sequence leads to a validation error.

Examples

Below, the record on the right is a valid upgrade of the module on the left. It adds an optional field `x2` at the end of the field sequence.

<pre>data T = T with x1 : Int</pre>	<pre>data T = T with x1 : Int x2 : Optional Text</pre>
---------------------------------------	--

Below, the record on the right is **not** a valid upgrade of the record on the left because it adds a new field `x2` before `x1` instead of adding it at the end of the field sequence.

<pre>data T = T with x1 : Int</pre>	<pre>data T = T with x2 : Optional Text x1 : Int</pre>
---------------------------------------	--

Below, the record on the right is **not** a valid upgrade of the record on the left because it drops field `x2`.

<pre>data T = T with x1 : Int x2 : Text</pre>	<pre>data T = T with x1 : Int</pre>
---	---------------------------------------

Below, the record on the right is **not** a valid upgrade of the record on the left because it changes the type of `x1` from `Int` to `Text`. `Text` is not a valid upgrade of `Int`.

<pre>data T = T with x1 : Int</pre>	<pre>data T = T with x1 : Text</pre>
---------------------------------------	--

Data Types - Variants

The new version of a variant may add new constructors at the end of the constructor sequence of the old version of that variant. The argument types of the constructors that the new variant has in common with the prior variant must be pairwise valid upgrades of the original types. This last rule also applies to constructors whose arguments are unnamed records, in which case the rules about record upgrade apply.

Adding an argument to a constructor without arguments leads to a validation error. In particular, adding an optional field to a constructor that previously had no arguments is not allowed.

Adding a constructor in the middle of the constructor sequence leads to a validation error.

Changing the order or the name of the constructor sequence leads to a validation error.

Removing a constructor leads to a validation error.

Enums cannot get upgraded to variants: adding a constructor with an argument at the end of the constructor sequence of an enum leads to a validation error.

Examples

Below, the variant on the right is a valid upgrade of the variant on the left. It adds a new constructor `C` at the end of the constructor sequence.

<pre>data T = A Int B Text</pre>	<pre>data T = A Int B Text C Bool</pre>
--------------------------------------	---

Below, the variant on the right is a valid upgrade of the variant on the left. It adds a new optional field to constructor `B`.

<pre>data T = A B { x : Int }</pre>	<pre>data T = A B { x : Int, y : Optional Text }</pre>
---	--

Below, the variant on the right is **not** a valid upgrade of the variant on the left because it adds a new constructor C before B instead of adding it at the end of the constructor sequence.

<pre>data T = A Int B Text</pre>	<pre>data T = A Int C Bool B Text</pre>
--	---

Below, the variant on the right is **not** a valid upgrade of the variant on the left because it changes the order of its constructors.

<pre>data T = A Int B Text</pre>	<pre>data T = B Text A Int</pre>
--	--

Below, the variant on the right is **not** a valid upgrade of the variant on the left because it drops constructor B.

<pre>data T = A Int B Text</pre>	<pre>data T = A Int</pre>
--	---------------------------------

Below, the variant on the right is **not** a valid upgrade of the variant on the left because it changes the type of B's argument from Text to Bool. Bool is not a valid upgrade of Text.

<pre>data T = A Int B Text</pre>	<pre>data T = A Int B Bool</pre>
--	--

Below, the variant on the right is **not** a valid upgrade of the variant on the left because it adds an argument to constructor B which didn't have one before.

<pre>data T = A Int B</pre>	<pre>data T = A Int B { x : Optional Text }</pre>
-------------------------------------	---

Below, the variant on the right is **not** a valid upgrade of the enum on the left. Enums cannot get upgraded to variants and T as defined on the left is an enum because none of its constructors have arguments.

<pre>data T = A B</pre>	<pre>data T = A B C Int</pre>
---------------------------------	---

Data Types - Enums

For the purpose of upgrade validation, enums can be treated as a special case of variants. The rules of the section on variants apply, only without constructor arguments.

Data Types - Type References

A type reference is an identifier that resolves to a type. For instance, consider the following module definitions, from two different packages:

```
-- In package q
module Dep where

data U = U with x : Int
type A = U
```

```
-- In package p
module M where
import qualified Dep

data T = T with x : Dep.A
```

In the definition of `T`, `Dep.A` is a type reference that resolves to the type with qualified name `Dep.U` in package `q`.

A reference `r2` to a data type upgrades a reference `r1` to a data type if and only if:

- `r2` resolves to a type `t2` with qualified name `q2` in package `p2`;
- `r1` resolves to a type `t1` with qualified name `q1` in package `p1`;
- The qualified names `q2` and `q1` are the same;
- Either the LF versions or `p1` and `p2` both support upgrades and package `p2` is a valid upgrade of package `p1`, or `p2` and `p1` are the exact same package.

It is worth noting that even when `t2` upgrades `t1`, `r2` only upgrades `r1` provided that package `p2` is a valid upgrade of package `p1` as a whole.

Examples

In these examples we assume the existence of packages `q-1.0.0` and `q-2.0.0` with LF version 1.17, and that the latter is a valid upgrade of the former.

In <code>q-1.0.0</code> :	In <code>q-2.0.0</code> :
<pre>module Dep where data U = C1 data V = V</pre>	<pre>module Dep where data U = C1 C2 data V = V</pre>

Then below, the module on the right is a valid upgrade of the module on the left.

<pre>module Main where -- imported from q-1.0.0 import qualified Dep data T = T Dep.U</pre>	<pre>module Main where -- imported from q-2.0.0 import qualified Dep data T = T Dep.U</pre>
---	---

However below, the module on the right is **not** a valid upgrade of the module on the left because `Dep.V` on the right belongs to package `q-1.0.0` which is not a valid upgrade of package `p-2.0.0`, even though the two definitions of `V` are the same.

<pre>module Main where -- imported from q-2.0.0 import qualified Dep data T = T Dep.V</pre>	<pre>module Main where -- imported from q-1.0.0 import qualified Dep data T = T Dep.V</pre>
---	---

Suppose now that `q-1.0.0` and `q-2.0.0` are both compiled to LF version 1.15 (which does not support upgrades). Then below, the module on the right is **not** a valid upgrade of the module on the left because the references to `U` on each side resolve to packages with different IDs.

<pre>module Main where -- imported from q-1.0.0 import qualified Dep data T = T Dep.U</pre>	<pre>module Main where -- imported from q-2.0.0 import qualified Dep data T = T Dep.U</pre>
---	---

Data Types - Builtin Types

Builtin scalar types like `Int`, `Text`, `Party`, etc. only upgrade themselves. In other words, it is never valid to replace them with another type.

Data Types - Parameterized Data Types

The upgrade validation for parameterized data types follows the same rules as non-parameterized data types, but also compares type variables. Type variables may be renamed.

Example

Below, the parameterized data type on the right is a valid upgrade of the parameterized data type on the left. As is valid with any record type, it adds an optional field.

```
data Tree a =
  Tree with
    label : a
    children : [Tree a]
```

```
data Tree b =
  Tree with
    label : b
    children : [Tree b]
    cachedSize : Optional Int
```

Data Types - Applied Parameterized Data Types

A type constructor application $T' \ U1' \ \dots \ Un'$ upgrades $T \ U1 \ \dots \ Un$ if and only if T' upgrades T and each Ui' upgrades the corresponding Ui .

Examples

Below, the module on the right is a valid upgrade of the module on the left. The record type T on the right upgrades the record type T on the left. As a result, the type constructor application $List \ T$ on the right upgrades the type constructor application $List \ T$ on the left. Same goes for $List$ and $Optional$.

```
module M where

data T = T {}

data Demo = Demo with
  field1 : List T
  field2 : Map T T
  field3 : Optional T
```

```
module M where

data T = T { i : Optional Int }

data Demo = Demo with
  field1 : List T
  field2 : Map T T
  field3 : Optional T
```

Below, the module on the right is a valid upgrade of the module on the left. The parameterized type C on the right upgrades the parameterized type C on the left. As a result, the type constructor application $C \ Int$ on the right upgrades the type constructor application $C \ Int$ on the left.

```
module M where

data C a = C { x : a }

data Demo = Demo with
  field1 : C T
```

```
module M where

data C a = C { x : a, y : Optional Int }

data Demo = Demo with
  field1 : C T
```

Interface and Exception Definitions

Neither interface definitions nor exception definitions can be upgraded. We strongly discourage uploading a package that defines interfaces or exceptions alongside templates, as these templates cannot benefit from smart contract upgrade in the future. Instead, we recommend declaring interfaces and exceptions in a package of their own that defines no template.

Interface Instances

Interface instances may be upgraded. Note however that the type signature of their methods and view cannot change between two versions of an instance since they are fixed by the interface definition, which is non-upgradable. Hence, the only thing that can change between two versions of an instance is the bodies of its methods and view.

Adding or deleting an interface leads to a validation error.

Examples

Assume an interface `I` with view type `IView` and a method `m`.

```
data IView = IView { i : Int }

interface I where
  viewtype IView
```

Then, below, the instance of `I` for template `T` on the right is a valid upgrade of the instance on the left. It changes the `view` expression and the body of method `m`.

```
template T
  with
    p : Party
    i : Int
  where
    signatory p

    interface instance I for T where
      view = IView i
      m = i
```

```
template T
  with
    p : Party
    i : Int
    j : Optional Int
  where
    signatory p

    interface instance I for T where
      view = IView (fromOptional i j)
      m = fromOptional i j
```

Below, the template on the right is **not** a valid upgrade of the template on the left because it removes the instance of `I` for template `T2`.

```

template T2
  with
    p : Party
    i : Int
  where
    signatory p

    interface instance I for T2 where
      view = IView i
      m = i

```

```

template T2
  with
    p : Party
    i : Int
  where
    signatory p

```

Below, the template on the right is **not** a valid upgrade of the template on the left because it adds a new instance of `I` for template `T3`.

```

template T3
  with
    p : Party
    i : Int
  where
    signatory p

```

```

template T3
  with
    p : Party
    i : Int
  where
    signatory p

    interface instance I for T3 where
      view = IView i
      m = i

```

46.1.9.2 Data Transformation: Runtime Semantics

A template version is selected whenever a contract is fetched, a choice is exercised, or an interface value is converted to a template value, according to a set of rules detailed below. We call this template the target template.

The contract is then transformed into a value that fits the type of the target template. Then, its metadata (signatories, stakeholders, key, maintainers) is recomputed using the code of the target template and compared against the existing metadata stored on the ledger: it is not allowed to change. The ensure clause of the contract is also re-evaluated: it must evaluate to `True`.

In addition, when a choice is exercised, its arguments are transformed into values that fit the type signature of the choice in the target template. The result of the exercise is then possibly transformed back to some other target type by the client (e.g. the generated java client code).

Below, we detail the rules governing target template selection, then explain how transformations are performed, and finally detail the rules of metadata re-computation.

Static Target Template Selection

In a non-interface fetch or exercise triggered by the body of a choice, the target template is determined by the dependencies of the package that defines the choice. In other words, it is statically known.

Interface fetches and exercises, on the other hand, are subject to dynamic target template selection, as detailed in [the next section](#). However, operations acting on interface values – as opposed to IDs – are static. Their mode of operation is detailed below.

Daml contracts are represented by one of two sorts of values at runtime: template values or interface values.

Template values are those whose concrete template type is statically known. They are obtained by directly constructing a template record, or by a call to `fetch`. Their runtime representation is a simple record.

Interface values are those whose concrete template type is not fully statically known, aside from the fact that it implements a given interface. They are obtained by applying `toInterface` to a template value. At runtime, they are represented by a pair consisting of:

- a record: the contract;
- a template type: the runtime type of that record.

For instance, if `c` is a contract of type `T` and `T` implements the interface `I`, then `toInterface c` evaluates to the pair `(c, T)`.

Note that the type of interface values is opaque: while it is useful to conceptualize interface values as pairs for defining the runtime semantics of the language, their actual implementation may vary and is not exposed to the user.

Let us assume an interface value `iv = (c, T)`. Then `fromInterface @U iv` evaluates as follow.

If `U` upgrades `T`, then it evaluates to `Some c'` where `c'` is the result of transforming `c` into a value of type `U`.

Otherwise, it evaluates to `None`.

Let us assume an interface value `iv = (c, T)` and an interface type `I`. Then `create @I iv` evaluates as follow.

If `T` does not implement `I` then an error is thrown.

Otherwise `create @T c` is evaluated.

Example 1

Assume two versions of a package called `dep`, defining a template `U` and its upgrade.

In <code>dep-1.0.0</code> :	In <code>dep-2.0.0</code> :
<pre> module Dep where template U with p : Party where signatory p </pre>	<pre> module Dep where template U with p : Party t : Optional Text where signatory p </pre>

Assume then some package `q` which depends on version `1.0.0` of `dep`.

```
[...]
name: q
version: 1.0.0
data-dependencies:
- dep-1.0.0.dar
```

Package `q` defines a template `S` with a choice that fetches a contract of type `U`.

```
import qualified Dep

template S
  with
    p : Party
  where
    signatory p

    choice GetU : Dep.U
    with
      cid : ContractId Dep.U
    where
      controller p
      do fetch cid
```

Finally assume a ledger that contains a contract of type `S` written by `q` and a contract of type `U` written by `dep-2.0.0`.

Contract ID	Type	Contract
4321	<code>q:T</code>	<code>T { p = 'Alice' }</code>
8765	<code>dep-2.0.0:U</code>	<code>U { p = 'Bob', t = None }</code>

When exercising choice `GetU 8765` on contract `4321` with package preference `dep-2.0.0`, we trigger a fetch of contract `5678`. Because package `q` depends on version `1.0.0` of `dep`, the target type for `U` is the one defined in package `dep-1.0.0`. Contract `5678` is thus downgraded to `U { p = 'Bob' }` upon retrieval. Note that the command preference for version `2.0.0` of package `dep` bears no incidence here.

Example 2

Assume an interface `I` with view type `IView` and a method `m`.

```
data IView = IView {}

interface I where
  viewtype IView
```

Assume then two versions of a template `T` that implements `I`.

```

template T
  with
    p : Party
  where
    signatory p

    interface instance I for T where
      view = IView {}

```

```

template T
  with
    p : Party
    i : Optional Int
  where
    signatory p

    interface instance I for T where
      view = IView {}

```

Finally, assume that the module defining the first version of `T` is imported as `V1`, and the module defining the second version of `T` is imported as `V2`. The expression `fromInterface @V2.T (toInterface @I (V1.T 'Alice'))` evaluates as follows:

`toInterface @I (@V1.T alice)` evaluates to the interface value `(V1.T { p = 'Alice' }, V1.T)`.

The type `V2.T` upgrades `V1.T` so `fromInterface` proceeds to transform `(V1.T { p = 'Alice' })` into a value of type `V2.T`.

The entire expression thus evaluates to `V2.T { p = 'Alice', i = None }`.

Dynamic Target Template Selection

In a top-level exercise triggered by a Ledger API command, or in an interface fetch or exercise triggered from the body of a choice, the rules of package preference detailed in [dynamic package resolution](#) determine the target template at runtime.

Example 1

Assume a package `p` with two versions. The new version adds an optional text field.

In <code>p-1.0.0</code> :	In <code>p-2.0.0</code> :
<pre> template T with p : Party where signatory p </pre>	<pre> template T with p : Party t : Optional Text where signatory p </pre>

Also assume a ledger that contains a contract of type `T` written by `p-1.0.0`, and another contract of written by `p-2.0.0`.

Contract ID	Type	Contract
1234	<code>p-1.0.0:T</code>	<code>T { p = 'Alice' }</code>
5678	<code>p-2.0.0:T</code>	<code>T { p = 'Bob', t = Some "Hello" }</code>

Then

Fetching contract 1234 with package preference `p-1.0.0` retrieves the contract and leaves it unchanged, returning `T { p = 'Alice' }`.

Fetching contract 1234 with package preference `p-2.0.0` retrieves the contract and successfully transforms it to the target template type, returning `T { p = 'Alice', t = None }`.
 Fetching contract 5678 with package preference `p-1.0.0` retrieves the contract and fails to downgrade it to the target template type, returning an error.
 Fetching contract 5678 with package preference `p-2.0.0` retrieves the contract and leaves it unchanged, returning `T { p = 'Bob', t = Some "Hello" }`.

Example 2

Assume an interface `I` with a choice `GetInt`

```
data IView = IView {}

interface I where
  viewtype IView
  getInt : Int

  choice GetInt : Int
  with
    p : Party
  controller p
  do
    pure (getInt this)
```

Now, assume two versions of a package called `inst`, defining a template `Inst` and its upgrade. The two versions of the template instantiate interface `I`, but their `getInt` method return different values.

In <code>inst-1.0.0</code> :	In <code>inst-2.0.0</code> :
<pre>template Inst with p : Party where signatory p interface instance I for T where view = IView getInt = 1</pre>	<pre>template Inst with p : Party where signatory p interface instance I for T where view = IView getInt = 2</pre>

Assume then some package `client` which defines a template whose choice `Go` exercises choice `GetInt` by interface.

```
template Client
  with
    p : Party
    icid : ContractId I
  where
    signatory p

    choice Go : Int
    controller p
    do
      exercise icid (GetInt p)
```

Finally assume a ledger that contains a contract of type `Inst` written by `inst-1.0.0`, and a contract

of type `Client` written by `client`.

Contract ID	Type	Contract
0123	<code>inst-1.0.0:Inst</code>	<code>Inst { p = 'Alice' }</code>
0456	<code>client:Client</code>	<code>Client { p = 'Alice' }</code>

Then:

When exercising choice `Go` on contract 0456 with package preference `inst-1.0.0`, we trigger an exercise by interface of contract 0123. Because `inst-1.0.0` is preferred, contract 0123 is upgraded to a value of type `inst-1.0.0::Inst` and its `getInt` method is executed. The result of the exercise is thus the value 1.

When exercising choice `Go` on contract 0456 but with package preference `inst-2.0.0` this time, `inst-2.0.0:Inst` is picked as the target template for 0123 and thus the exercise returns the value 2. Note that the fact that the exercise stored on the ledger is of type `inst-1.0.0:Inst` bears no incidence on the `getInt` method that is eventually executed.

Example 3

Assume now a package `r` with two versions. They define a template with a choice, and version `2.0.0` adds an optional field to the parameters of the choice. The return type of the choice is also upgraded.

In <code>r-1.0.0</code> :	In <code>r-2.0.0</code> :
<pre>module M where data Ret = Ret with template V with p : Party where signatory p choice C : Ret with i : Int controller p do return Ret</pre>	<pre>module M where data Ret = Ret with j : Optional Int template V with p : Party where signatory p choice C : Ret with i : Int j : Optional Int controller p do return Ret with j = j</pre>

Also assume a ledger that contains a contract of type `V` written by `r-1.0.0`.

Contract ID	Type	Contract
9101	<code>r-1.0.0:V</code>	<code>V { p = 'Alice' }</code>

Then:

Exercising `C` with `i=1` on contract 9101 with package preference `r-2.0.0` will execute the code of `C` as defined in `r-2.0.0`. The parameter sequence `i=1` is thus transformed into the parameter sequence `i=1, j=None` to match its parameter types. The exercise then returns the value `Ret with j=None`. It is up to the client code (e.g. the caller of the ledger API) to

transform this to a value that fits the return type it expects. For instance, a client which only knows about version 1.0.0 of package `r` would expect a value of type `Ret` and would thus transform the value `Ret with j=None` back to `Ret`.

Exercising `C` with `i=1` on contract 9101 with package preference `r-1.0.0` will execute the code of `C` as defined in `r-1.0.0`. The parameter sequence requires therefore no transformation. The exercise returns the value `Ret`.

Exercising `C` with `i=1 j=Some 2` on contract 9101 with package preference `r-2.0.0` will execute the code of `C` as defined in `r-2.0.0`. Again, the parameter sequence no transformation. The exercise returns the value `Ret with j=Some 2`.

Exercising `C` with `i=1 j=Some 2` on contract 9101 with package preference `r-1.0.0` will fail with a runtime error as the parameter sequence `i=1 j=Some 2` cannot be downgraded to the parameter sequence of `C` as defined in `r-1.0.0`.

Transformation Rules

Once the target type has been determined, the data transformation rules themselves follow the [upgrading rules of protocol buffers](#).

Records and Parameters

Given a record type and its upgrade, referred to respectively as `T-v1` and `T-v2` in the following,

<pre>data T = T with x1 : T1 ... xn : Tn</pre>	<pre>data T = T with x1 : T1' ... xn : Tn' y1 : Optional U1 ... ym : Optional Um</pre>
--	--

A `T-v1` value `T { x1 = v1, ..., xn = vn }` is upgraded to a `T-v2` value by setting the additional fields to `None` and upgrading `v1...vn` recursively. The transformation results in a value `T { x1 = v1', ..., xn = vn', y1 = None, ..., ym = None }`, where `v1'...vn'` is the result of upgrading `v1...vn` to `T1' ... Tn'`.

A `T-v2` value of the shape `T { x1 = v1, ..., xn = vn, y1 = None, ..., ym = None }` is downgraded to a `T-v1` value by dropping additional fields and downgrading `v1...vn` recursively. The transformation results in a value `T { x1 = v1', ..., xn = vn' }` where `v1'...vn'` is the result of downgrading `v1 ... vn` to `T1 ... Tn`.

Attempting to downgrade a `T-v2` value where at least one `yi` is a `Some _` results in a runtime error.

The same transformation rules apply to template parameters and choice parameters.

Variants and Enums

Given a variant type and its upgrade, referred to respectively as $V-v1$ and $V-v2$ in the following,

<pre>data V = = C1 T1 ... Cn Tn</pre>	<pre>data V = = C1 T1 ' ... Cn Tn ' D1 U1 ... Dm Um</pre>
---	---

A $V-v1$ value $C_i \ v_i$ is upgraded to a $V-v2$ value by upgrading v_i recursively. The transformation results in a value $C_i \ v_i'$ where v_i' is the result of upgrading v_i to T_i' .

A $V-v2$ value $C_i \ v_i$ is downgraded to a $V-v1$ value by downgrading v_i recursively. The transformation results in a value $C_i \ v_i'$ where v_i' is the result of downgrading v_i to T_i .

Attempting to downgrade a $V-v2$ value of the form $D_j \ v_j$ results in a runtime error.

The same transformation rules apply to enum types, constructor arguments aside.

Other Types

Types that aren't records or variants are `pass-through` for the upgrade and downgrade transformations:

- Values of scalar types are trivially transformed to themselves.

- The payload of an `Optional` is recursively transformed.

- The elements of `Lists` are recursively transformed.

- The keys and values of `Maps` are recursively transformed.

Metadata

For a given contract, metadata is every information outside of the contract parameters that is stored on the ledger for this contract. Namely:

- The contract signatories;

- The contract stakeholders (the union of signatories and observers);

- The contract key;

- The maintainers of the contract key.

The metadata of two contracts are equivalent if and only if:

- their signatories are equal;

- their stakeholders are equal;

- their keys, after transformation to the maximum version of the two contracts, are equal;

- their maintainers are equal.

Upon retrieval and after conversion, the metadata of a contract is recomputed using the code of the target template. It is a runtime error if the recomputed metadata is not equivalent to that of the original contract.

Note: A given implementation may choose to perform the equivalence check differently from what is described above, as long as the result is semantically equivalent.

Example 1

Below the template on the right is a valid upgrade of the template on the left.

In p-1.0.0:	In p-2.0.0:
<pre>template T with sig : Party where signatory sig</pre>	<pre>template T with sig : Party additionalSig : Optional Party where signatory sig, fromOptional [] ↪ additionalSig</pre>

Assume a ledger that contains a contract of type T written by p-1.0.0.

Contract ID	Type	Contract
1234	p-1.0.0:T	T { sig = ['Alice'] }

Fetching contract 1234 with target type p-2.0.0:T retrieves the contract and successfully transforms it into a value of type p-2.0.0:T:T { sig = 'Alice', additionalSig = None }. The signatories of this transformed contract are then computed using the expression sig, fromOptional [] additionalSig, which evaluate to the list ['Alice']. This list is then compared to signatories of the original contract stored on the ledger: ['Alice']. They match and thus the upgrade is valid.

On the other hand, below, the template on the right is **not** a valid upgrade of the template on the left.

In p-1.0.0:	In p-2.0.0:
<pre>template T with sig : Party where signatory sig</pre>	<pre>template T with sig : Party where signatory sig, sig</pre>

Assume the same ledger as above. Fetching contract 1234 with target type p-2.0.0:T retrieves the contract and again successfully transforms it into the value T { sig = 'Alice', additionalSig = None }. The signatories of this transformed contract are then computed using the expression sig, sig, which evaluate to the list ['Alice', 'Alice']. This list is then compared to signatories of the original contract stored on the ledger: ['Alice']. They do not match and thus the upgrade is rejected at runtime.

Example 2

Below the module on the right is a valid upgrade of the module on the left:

In p-1.0.0:	In p-2.0.0:
<pre> module M where data MyKey = MyKey with p : Party template T with sig : Party where signatory sig key MyKey p : MyKey maintainer key.p </pre>	<pre> module M where data MyKey = MyKey with p : Party i : Optional Int template T with sig : Party i : Optional Int where signatory sig key MyKey p i : MyKey maintainer key.p </pre>

Assume a ledger that contains a contract of type T written by p-1.0.0.

Contract ID	Contract Type	Contract Key	Contract
1234	p-1.0.0:T	MyKey { p = 'Alice' }	T { sig = 'Alice' }

Fetching contract 1234 with package preference p-2.0.0 retrieves the contract and successfully transforms it into a value of type p-2.0.0:T:T { sig = 'Alice', i = None }. The key of this transformed contract is then computed using the expression `MyKey p i`, which evaluates to the value `MyKey { p = 'Alice', i = None }`. This value is then compared against the key of the original contract after transformation to a value of type p-2.0.0:MyKey:MyKey { p = 'Alice', i = None }. The two values match and thus the upgrade is valid.

On the other hand, below, the module on the right is **not** a valid upgrade of the module on the left:

In p-1.0.0:	In p-2.0.0:
<pre> module M where data MyKey = MyKey with p : Party template T with sig : Party where signatory sig key MyKey p : MyKey maintainer key.p </pre>	<pre> module M where data MyKey = MyKey with p : Party i : Optional Int template T with sig : Party where signatory sig key MyKey p (Some 0) : MyKey maintainer key.p </pre>

Assume the same ledger as above. Fetching contract 1234 with package preference p-2.0.0 retrieves the the contract and again successfully transforms it into the value T { sig = 'Alice' }. The key of this transformed contract is then computed using the expression `MyKey p (Some 0)`,

which evaluates to the value `MyKey { p = 'Alice', i = Some 0 }`. This value is then compared against the original contract's key after transformation to a value of type `p-2.0.0:MyKey: MyKey { p = 'Alice', i = None }`. The two values do not match and thus the upgrade is rejected at runtime.

Ensure Clause

Upon retrieval and after conversion, the ensure clause of a contract is recomputed using the code of the target template. It is a runtime error if the recomputed ensure clause evaluates to `False`.

Examples

Below, the template on the right is **not** a valid upgrade of the template on the left because its ensure clause will evaluate to `False` for contracts that have been written using the template on the left with `n = 0`.

```
template T
  with
    sig : Party
    n : Int
  where
    signatory sig
    ensure n >= 0
```

```
template T
  with
    sig : Party
    n : Int
  where
    signatory sig
    ensure n > 0
```

Interface Views

The view for a given interface instance is not allowed to change between two versions of a contract. When a contract is fetched or exercised by interface, its view according to the code of the target template is compared to its view according to the code of the template that was used when the contract was created. It is a runtime error if the two views differ.

Example

Assume an interface `I` with view type `IView` and a method `m`.

```
data IView = IView { i : Int }

interface I where
  viewtype IView
  m : Int
```

In that case, the template on the right below is a valid upgrade of the template on the left.

In p-1.0.0:	In p-2.0.0:
<pre> template T with p : Party i : Int where signatory p interface instance I for T where view = IView i m = i </pre>	<pre> template T with p : Party i : Int j : Optional Int where signatory p interface instance I for T where view = IView (fromOptional i j) m = fromOptional i j </pre>

Assume a ledger that contains a contract of type T written by p-1.0.0.

Contract ID	Type	Contract
1234	p-1.0.0:T	T { p = 'Alice', i = 42 }

Fetching contract 1234 by interface with package preference p-2.0.0 retrieves the contract and computes its view according to p-1.0.0: IView 42. The contract is then transformed into a value of type p-2.0.0:T: T { sig = 'Alice', i = 42, j = None } and its view is computed again, this time according to p-2.0.0: IView 42. Because the two views agree, the fetch is successful.

On the other hand, below, the template on the right is **not** a valid upgrade of the template on the left.

In p-1.0.0:	In p-2.0.0:
<pre> template T with p : Party i : Int where signatory p interface instance I for T where view = IView i m = i </pre>	<pre> template T with p : Party i : Int where signatory p interface instance I for T where view = IView (i+1) m = i </pre>

Assume the same ledger as above. Fetching contract 1234 by interface with package preference p-2.0.0 again retrieves the contract and computes its view according to p-1.0.0: IView 42. The contract is then transformed into a value of type p-2.0.0:T: T { sig = 'Alice', i = 42 } and its view is computed again, this time according to p-2.0.0: IView 43. Because the two views differ, the fetch is rejected at runtime.

Key Transformation in FetchByKey and LookupByKey

When fetching or looking up a contract by key in the body of a choice, the type of the key expression is known at compile time. Let us call it the target type. The returned contract, if any, verifies that its key, after transformation to the target type, matches the key used for querying.

Example

Below the module on the right is a valid upgrade of the module on the left:

In p-1.0.0:	In p-2.0.0:
<pre> module M where data MyKey = MyKey with p : Party template T with sig : Party where signatory sig key MyKey p : MyKey maintainer key.p </pre>	<pre> module M where data MyKey = MyKey with p : Party i : Optional Int template T with sig : Party i : Optional Int where signatory sig key MyKey p i : MyKey maintainer key.p </pre>

Assume a ledger that contains a contract of type T written by p-1.0.0.

Contract ID	Contract Type	Contract Key	Contract
1234	p-1.0.0:T	MyKey { p = 'Alice' }	T { sig = 'Alice' }

Finally, assume a third package which depends on p-2.0.0 and defines a choice involving the following lookup by key:

```

choice C : ()
  controller ctl
  do
    cid <- lookupByKey @T (MyKey alice None)
    ...

```

The static type of the key being looked up is thus p-2.0.0:MyKey. The key of contract 1234, once transformed to a value of type p-2.0.0:MyKey, becomes MyKey { p = 'Alice', i = None }. This matches the key being looked up, so cid is bound to Some 1234.

46.1.9.3 LF 1.17 Values in the Ledger API

Commands and queries that involve LF 1.17 templates or interfaces have relaxed validation rules for ingested values. Returned values are subject to normalization.

Value Validation in Commands

In the following examples, the *target template* of a command is the template or interface identified by the `template_id` field of the command after [dynamic package resolution](#).

A value featured in a command (e.g. `create_arguments`) has *expected type* `T` if the value needs to type-check against `T` in order to satisfy the type signatures of the target template of the command. Note that this definition necessarily extends to sub-values.

In a record value of the form `Constructor { field1 = v1, ..., fieldn = vn }`, `vi` is a *trailing None* if for all $n \geq j \geq i$, `vj = None`.

On submission of a command whose target template is defined in an LF 1.17 package, the validation rules for values are relaxed as follows:

The `record_id`, `variant_id`, and `enum_id` fields of values, if present, are only checked against the module and type name of the expected type for that value. The package ID component of these fields is ignored.

In record values where all field names are provided, any fields of value `None` may be omitted.

In record values where not all field names are provided, fields must be provided in the same order as that of the record type definition, and trailing Nones may be omitted.

These rules apply for all sub-values, even those whose type is defined in an LF 1.15 or earlier package.

Example 1

Assume a LF 1.17 package called `example1-1.0.0` which defines a template called `T` in a module called `Main`.

```
module Main where

template T
  with
    p : Party
  where
    signatory p
```

Assume another package called `other-1.0.0` which defines a different template also called `T` in a module also called `Main`.

```
module Main where

template T
  with
    s : Party
    i : Int
  where
    signatory s
```

Then the ledger API will accept Create commands for `example1-1.0.0:Main.T` whose create arguments are annotated with type `other-1.0.0:T:Main.T`, even though the type annotation is wrong.

In other words, the following console commands succeed:

```
@ val createCmd = Command(
  command = Command.Command.Create(
    value = CreateCommand(
      templateId = Some(
        value = Identifier(packageId = packageIdExample1, moduleName = "Main",
entityName = "T")),
      createArguments = Some(
        value = Record(
          recordId = Some(
            Identifier(
              packageId = packageIdOther,
              moduleName = "Main",
              entityName = "T"
            )
          ),
          fields = Seq(
            RecordField(
              label = "p",
              value = Some(
                value = Value(sum = Value.Sum.Party(value = sandbox.adminParty.
toLf))
              )
            )
          )
        )
      )
    )
  )
)

@ sandbox.ledger_api.commands.submit(Seq(sandbox.adminParty), Seq(createCmd))
```

This is because the module and type names of the type annotation, `Main` and `T`, match those of the expected type: `example1-1.0.0:Main.T`.

Assume now a LF 1.15 package called `example1-1f115-1.0.0` with the same contents as `example1-1.0.0`. Trying to submit a `Create` command for `example1-1.0.0:Main.T` whose create argument are annotated with type `other-1.0.0:T:Main.T` fails:

```
ERROR c.d.c.e.CommunityConsoleEnvironment - Request failed for sandbox.
GrpcClientError: INVALID_ARGUMENT/COMMAND_PREPROCESSING_FAILED(8,e448b57c):
  Mismatching variant id, the type tells us
ba561ce9adfc91b583752a842e72530f10ee0d93e729d19ef3179cd80daf43ca:Main:T,
  but the value tells us
39fb87e17e104daeaf10fdb32d282d004a29d5ec14db6579605456c42d5678d:Main:T
Request: SubmitAndWaitTransactionTree(
  actAs = sandbox::12208e04d297...,
  readAs = Seq(),
  commandId = '',
  workflowId = '',
  submissionId = '',
  deduplicationPeriod = None(),
  applicationId = 'CantonConsole',
  commands = ...
)
```

(continues on next page)

(continued from previous page)

...

This is because the relaxed validation rules only apply to LF 1.17 templates. The behavior for LF 1.15 and earlier remains unchanged.

Example 2

Assume a LF 1.17 package called `example2-1.0.0` which defines a template with two optional fields: one in leading position, and one in trailing position.

```
module Main where

template T
  with
    i : Optional Int
    p : Party
    j : Optional Int
  where
    signatory p
```

Then submitting a Create command for `example2-1.0.0:Main.T` which only provides `p` by name and no other field succeeds:

```
@ val createCmd = Command(
  command = Command.Command.Create(
    value = CreateCommand(
      templateId = Some(value = Identifier(packageId = packageIdExample2,
↳ moduleName = "Main", entityName = "T")),
      createArguments = Some(
        value = Record(
          recordId = None,
          fields = Seq(
            RecordField(
              label = "p",
              value = Some(value = Value(sum = Value.Sum.Party(value = sandbox.
↳ adminParty.toLf)))
          )
        )
      )
    )
  )
)

@ sandbox.ledger_api.commands.submit(Seq(sandbox.adminParty), Seq(createCmd))

Value normalization in Ledger API responses

A Ledger API value (e.g. `create_arguments` in a `CreatedEvent`) is said to be in normal form if none of its sub-values (itself included) has trailing Nones.

Starting with Daml 2.10, values in Ledger API non-verbose responses are subject to normalization whenever the transaction involves an LF 1.17 template or interface. The normalization extends to all sub-values, including those whose type is defined in an LF 1.15 or earlier package.

When no LF 1.17 package is involved in a transaction or when verbose mode is requested, then the values in Ledger API responses are guaranteed **not** to be in normal form.

Example 1

Assume a LF 1.17 package called `example1-1.0.0` which defines a template `T` and a record `Record` in a module called `Main`.

```
module Main where

data Record = Record { ri : Optional Int, rj : Int, rk : Optional Int }
  deriving (Eq, Show)

template T
  with
    p : Party
    i : Optional Int
    r : Record
    j : Optional Int
  where
    signatory p
```

Also assume a ledger that contains a contract of type `T` written by `example1-1.0.0` where all the optional fields are set to `None`.

```
val createCmd = ledger_api_utils.create(
  packageIdExample1,
  "Main",
  "T",
  Map(
    "p" -> sandbox.adminParty,
    "i" -> None,
    "r" -> Map("ri" -> None, "rj" -> 1, "rk" -> None),
    "j" -> None)
)

sandbox.ledger_api.commands.submit(Seq(sandbox.adminParty), Seq(createCmd))
```

Then querying the ledger's active contract set in non-verbose mode returns the following:

```
@ sandbox.ledger_api.acs.of_party(sandbox.adminParty, verbose=false)
res15: Seq[com.digitalasset.canton.admin.api.client.commands.
↳LedgerApiTypeWrappers.WrappedCreatedEvent] = List(
  WrappedCreatedEvent(
    event = CreatedEvent(
      ...
      createArguments = Some(
        value = Record(
          recordId = None,
```

(continues on next page)

(continued from previous page)

```

        fields = Vector(
          RecordField(
            label = "",
            value = Some(value = Value(sum = Party(value =
↪ "sandbox::122010fdef685011beecd318f03c9d82bf1e2d45950bdb0fceb3497a112ee17f9476
↪ ")))
          ),
          RecordField(label = "", value = Some(value = Value(sum =
↪ Optional(value = Optional(value = None))))),
          RecordField(
            label = "",
            value = Some(
              value = Value(
                sum = Record(
                  value = Record(
                    recordId = None,
                    fields = Vector(
                      RecordField(label = "", value = Some(value = Value(sum =
↪ Optional(value = Optional(value = None))))),
                      RecordField(label = "", value = Some(value = Value(sum =
↪ Int64(value = 1L))))
                    )
                  )
                )
              )
            )
          )
        )
      )
    )
  )
)

```

Note that not only has the third template argument (originally `j`) been omitted from the response, but also the third field of the nested record (originally `rk`). Note also that despite being optional fields of value `None`, the second template argument (originally `i`) and the first nested record field (originally `ri`) are present in the response because they are not in trailing positions.

Example 2

Assume a LF 1.15 package called `record-lf115-1.0.0` which defines a record `Record` with a trailing optional field in a module called `LF115`.

```

module LF115 where

data Record = Record { ri : Int, rj : Optional Int }
  deriving (Eq, Show)

```

Also assume a LF 1.17 package called `example2-1.0.0` which defines a template `T` in a module called `Main`. The template has a field of type `record-lf115-1.0.0:LF115.Record`.

```

module Main where

```

(continues on next page)

(continued from previous page)

```

template T
  with
    p : Party
    r : LF115.Record
  where
    signatory p

```

Note: It is not recommended for LF 1.17 templates to depend on LF 1.15 serializable values.

Finally, assume a ledger that contains a contract of type `T` written by `example2-1.0.0` where the trailing optional field of `r` is set to `None`.

```

val createCmd = ledger_api_utils.create(
  packageIdExample2,
  "Main",
  "T",
  Map(
    "p" -> sandbox.adminParty,
    "r" -> Map("ri" -> 1, "rj" -> None))
)

sandbox.ledger_api.commands.submit(Seq(sandbox.adminParty), Seq(createCmd))

```

Then querying the ledger's active contract set in non-verbose mode returns the following:

```

sandbox.ledger_api.acs.of_party(sandbox.adminParty, verbose=false)

res15: Seq[com.digitalasset.canton.admin.api.client.commands.
↳ LedgerApiTypeWrappers.WrappedCreatedEvent] = List(
  WrappedCreatedEvent(
    event = CreatedEvent(
      ...
      createArguments = Some(
        value = Record(
          recordId = None,
          fields = Vector(
            RecordField(
              label = "",
              value = Some(
                value = Value(sum = Party(value =
↳ "sandbox::1220c70e4430e82758d9377f86a4f87e1d98d8b1f259bb71a0e099e886608844fbf0
↳ ))
              )
            ),
            RecordField(
              label = "",
              value = Some(
                value = Value(
                  sum = Record(
                    value = Record(
                      recordId = None,
                      fields = Vector(RecordField(label = "", value = Some(value
↳ = Value(sum = Int64(value = 1L))))
                    )

```

(continues on next page)

(continued from previous page)

```

    )
  )
)
)
)
)
),
...
)
)
)
)

```

Note that the trailing `None` field in the nested LF 1.15 record has been omitted from the response. This is because the normalization of LF 1.17 values extends to all subvalues, including those defined in LF 1.15 packages.

Example 3

Assume the same LF 1.15 package `record-lf115-1.0.0` as in Example 2.

```

module LF115 where

data Record = Record { ri : Int, rj : Optional Int }
  deriving (Eq, Show)

```

Also assume a LF 1.17 package called `example3-1.0.0` which defines a template `T` in a module called `Main`. The template defines a choice `C` which returns a value of type `record-lf115-1.0.0:LF115.Record` with a trailing `None`.

```

module Main where

template T
  with
    p : Party
  where
    signatory p

    nonconsuming choice C : LF115.Record
      controller p
      do pure (LF115.Record { ri = 1, rj = None })

```

Finally, assume a creation event `createdEvent` for this template. Exercising choice `C` on this contract yields the following response:

```

val createdEvent = sandbox.ledger_api.acs.of_party(sandbox.adminParty, □
  ↳ verbose=false).head.event
val exCmd = ledger_api_utils.exercise("C", Map(), createdEvent)
val exercisedEvent = sandbox.ledger_api.commands.submit(Seq(sandbox.adminParty), □
  ↳ Seq(exCmd))
sandbox.ledger_api.transactions.trees(Set(sandbox.adminParty), 2, □
  ↳ verbose=false) (1)

res18: com.daml.ledger.api.v1.transaction.TransactionTree = TransactionTree (
  ...
  eventsById = Map(

```

(continues on next page)

(continued from previous page)

```

"#1220be66a5da4596a4a14fbee9c3e020760b895040f2478a4d0f43387a5711554d4:0" ->
↳ TreeEvent(
  kind = Exercised(
    value = ExercisedEvent(
      ...
      exerciseResult = Some(
        value = Value(
          sum = Record(
            value = Record(
              recordId = None,
              fields = Vector(RecordField(label = "", value = Some(value =
↳ Value(sum = Int64(value = 1L))))))
        )
      )
    ),
    ...
  )
)
),
...
)
),
...
)

```

Note that the trailing optional field `Ⓜ` is omitted from the response. This is because the transaction created by the exercise involves a LF 1.17 template. All of the transaction's subvalues are therefore normalized. This includes values of types defined in LF 1.15 packages.

46.2 Canton Advanced Architecture

46.2.1 Contract Keys in Canton

Daml provides a `contract key` mechanism for contracts, similar to primary keys in relational databases. When using multi-sync-domain topologies, Canton will support the full syntax of contract keys, but only a reduced semantics. That is, all valid Daml contracts using keys will run on Canton, but their behavior may deviate from the prescribed one. This document explains the deviation, as well as ways of recovering the full functionality of keys in some scenarios. It assumes a reasonable familiarity with Daml.

Note: This section covers a preview feature, when using contract keys in a multi-sync-domain setup. By default, contract key uniqueness is enabled, and therefore this section does not apply. However, contract key uniqueness will soon be deprecated, as uniqueness cannot be enforced among multiple sync domains. We encourage you to build your models already anticipating this change.

Keys have two main functions:

Simplifying the modeling of mutable state in Daml. Daml contracts are immutable and can be only created and archived. Mutating a contract `C` is modeled by archiving `C` and creating a new contract `C'` which is a modified version of `C`. Other than keys, Daml offers no means to capture the relation between `C` and `C'`. After archiving `C`, any contract `D` that contains the contract ID of `C` is left with a dangling reference. This makes it cumbersome to model

mutable state that is split across multiple contracts. Keys provide mutable references in Daml; giving `C` and `C'` the same key `K` allows `D` to store `K` as a reference that will start pointing to `C'` after archiving `C`.

Checking that no active contract with a given key exists at some point in time. This mainly serves to provide uniqueness guarantees, which are useful in many cases. One is that they can serve to de-duplicate data coming from external sources. Another one is that they allow natural mutable references, e.g., referring to a user by their username or e-mail.

Canton participants and sync domains can be run in two modes:

1. In **unique-contract-key (UCK) mode**, contract keys in Canton provide both functions; there can be at most one active contract with a given key at any point in time. However, only UCK participants can connect to UCK sync domains and the first UCK sync domain a UCK participant connects to is the only sync domain that the participant can connect to in its lifetime. UCK sync domains and their participants are thus isolated islands that are deprived of Canton's composability and interoperability features.
2. In **non-unique-keys mode**, contract keys in Canton provide the first, but not the second function, at least not without additional effort or restrictions. In particular:
 1. In Canton, two (or more) active contracts with the same key may exist simultaneously on the same or different sync domains.
 2. If no submitting party is a stakeholder of an active contract instance of template `Template` with the key `k` visible on the submitting participant when the participant processes the submission, then a `lookupByKey @Template k` may return `None` even if an active contract instance of template `Template` with the key `k` exists on the virtual shared ledger at the point in time when the transaction is committed.
 3. A `fetchByKey @Template k` or an `exerciseByKey @Template k` or a positive `lookupByKey @Template k` (returning `Some cid`) may return any active contract of template `Template` with key `k`.

In the remainder of the document we:

give [more detailed examples](#) of the differences above
 give an [overview of how keys are implemented](#) so that you can better understand their behavior
 show [workarounds for recovering the uniqueness functionality](#) in particular scenarios on normal sync domains
 give a [formal semantics of keys](#) in Canton, in terms of the [Daml ledger model](#)
 explain how to [run a sync domain in UCK mode](#).

46.2.1.1 Synchronization Domains with Uniqueness Guarantees

By default, Canton sync domains and participants are currently configured to provide unique contract key (UCK) semantics. This will be deprecated in the future, as such a uniqueness constraint cannot be supported on a distributed system in a useful way. The [semantic differences from the ledger model](#) disappear if the transactions are submitted to a participant connected to a Canton sync domain in [UCK mode](#). The [workarounds](#) are therefore not needed.

A UCK participant can connect only to a UCK sync domain. Moreover, once it has successfully connected to a UCK sync domain, it will refuse to connect to another sync domain. Accordingly, conflict detection on a single sync domain suffices to check for key uniqueness. Participants connected to a UCK sync domain check for key conflicts whenever they host one of the key maintainers:

When a contract is created, they check that there is no other active contract with the same key. When the submitted transaction contains a negative key lookup, the participants check that there is indeed no active contract for the given key.

Warning: Daml workflows deployed on a UCK sync domain are locked into this sync domain. They cannot use Canton's composability and interoperability features because the participants will refuse to connect to other sync domains.

46.2.1.2 Non-Unique Contract Keys Mode

This section explains how contract keys behave on participants connected to Canton sync domains without unique contract keys. This mode can be activated by setting

```
canton {
  domains {
    alpha {
      // subsequent changes have no effect and the mode of a node can never be
      ↪changed
      init.domain-parameters {
        unique-contract-keys = false
        protocol-version = 7
      }
    }
  }

  participants {
    participant1 {
      // subsequent changes have no effect and the mode of a node can never be
      ↪changed
      init.parameters.unique-contract-keys = false
    }
  }
}
```

Note: The non-unique contract keys feature is preview-only. Currently, multiple keys will override each other.

Examples of Semantic Differences

Double Key Creation

Consider the following template:

```
template Keyed
with
  sig: Party
  k: Int
where
  signatory sig
  key (sig, k): (Party, Int)
  maintainer key._1
```

The Daml contract key semantics prescribe that no two active `Keyed` contracts with the same keys should exist. For example, consider the following Daml script:

```
multiple = script do
  alice <- allocateParty "alice"
  submitMustFail alice $ do
    createCmd (Keyed with sig = alice, k = 1)
    createCmd (Keyed with sig = alice, k = 1)
  pure ()
```

Alice's submission must fail, since it attempts to create two contracts with the key (Alice, 1). In Canton, however, the submission is legal and will succeed (if executed, for example, through Daml Script). Thus, you cannot directly rely on keys to ensure the uniqueness of user-chosen usernames or external identifiers (e.g., order identifiers, health record identifiers, entity identifiers) in Canton.

False lookupByKey Negatives

Similarly, your code might rely on the negative case of a lookupByKey:

```
template Initialization
  with
    sig: Party
    k: Int
  where
    signatory sig

template Orchestrator
  with
    sig: Party
  where
    signatory sig

    nonconsuming choice Initialize: Optional (ContractId Initialization)
      with
        k: Int
        controller sig
      do
        optCid <- lookupByKey @Keyed (sig, k)
        case optCid of
          None -> do
            create Keyed with ..
            time <- getTime
            cid <- create Initialization with sig, k
            pure $ Some cid
          Some _ -> pure None
```

When running a process (represented by the Initialization template here), you might use a pattern like above to ensure that it is run only once. The Initialization template does not have a key. Nevertheless, if all processing happens through the Orchestrator template, there will only ever be one Initialization created for the given party and key. For example, the following script creates only one Initialization contract:

```
lookupNone = script do
  alice <- allocateParty "alice"
  orchestratorId <- submit alice do
    createCmd Orchestrator with sig = alice
  submit alice do
```

(continues on next page)

(continued from previous page)

```

exerciseCmd orchestratorId Initialize with k = 1
submit alice do
  exerciseCmd orchestratorId Initialize with k = 1

```

In scripts, transactions are executed sequentially. Alice's second submission above will always find the existing `Keyed` contract, and thus execute the `Some` branch of the `Initialize` choice. In real-world applications, transactions may run concurrently. Assume that `initTx1` and `initTx2` are run concurrently, and that these are the first two transactions running the `Initialize` choice. Then, during their preparation, both of them might execute the `None` branch (i.e., `lookupByKey` might return a negative result), and thus both might try to create the `Initialization` contract. However, negative `lookupByKey` results must be committed to the ledger, and the [key consistency requirements](#) prohibit both of them committing. Thus, one of `initTx1` and `initTx2` might fail, or they both might succeed (if one of them sees the effects of the other and then executes the `Some` branch), but in either case, only one `Initialization` contract will be created.

In Canton, however, it is possible that both `initTx1` and `initTx2` execute the `None` branch, yet both get committed. For example, if the participant processes the submissions for `initTx1` and `initTx2` concurrently, neither will see `initTx1` the `Initialization` contract created by `initTx2` nor vice versa. Canton orders the transactions only after the commands have been interpreted, and in normal mode it does not check the consistency of negative lookup by keys after ordering any more. Thus, two `Initialization` contracts may get created.

Semantics of `fetchByKey` and Positive `lookupByKey`

Daml also provides a `fetchByKey` operation. Daml commands are evaluated against some active contract set. When Daml encounters a `fetchByKey` command, it tries to find an active contract with the given key (and fails if it cannot). Since Daml semantics prescribe that only one such contract may exist, it is clear which one to return. For example, consider the script:

```

fetchSome = script do
  alice <- allocateParty "alice"
  keyedId1 <- submit alice do
    createCmd Keyed with sig = alice, k = 1
  keyedId2 <- submitMustFail alice do
    createCmd Keyed with sig = alice, k = 1
  (foundId, _) <- submit alice do
    createAndExerciseCmd (KeyedHelper alice) $ FetchByKey (alice, 1)
  assert $ foundId == keyedId1
  optFoundId <- submit alice do
    createAndExerciseCmd (KeyedHelper alice) $ LookupByKey (alice, 1)
  assert $ optFoundId == Some keyedId1

```

The script uses a helper template `KeyedHelper` shown at the end of this section because `fetchByKey` and `lookupByKey` [cannot be used directly in a Daml script](#).

Daml's contract key semantics says that Alice's second submission must fail, since a contract with the given key already exists. Thus, her third submission will always succeed, and return `keyedId1`, since this is the only `Keyed` contract with the key (`Alice, 1`). Similarly, her fourth submission will also successfully find a contract, which will be `keyedId1`.

As discussed earlier, Alice's second submission in the above script will succeed in Canton. Alice's third and fourth submissions thus may return different contract IDs, with each returning either `keyedId1`, or `keyedId2`. Whichever one is returned, a successful `fetchByKey` and `lookupByKey`

still guarantees that the returned contract is active at the time when the transaction gets committed. As mentioned earlier, negative `lookupByKey` results may be spurious.

```
template KeyedHelper
  with
    p: Party
  where
    signatory p

    choice FetchByKey: (ContractId Keyed, Keyed)
      with keyP: (Party, Int)
      controller p
      do fetchByKey @Keyed keyP

    choice LookupByKey: Optional (ContractId Keyed)
      with keyP: (Party, Int)
      controller p
      do lookupByKey @Keyed keyP
```

Canton's Implementation of Keys

Internally, a Canton participant node has a component that provides the gRPC interface (the `Ledger API Server`), and another component that synchronizes participants (the `sync service`). When a command is submitted, the Ledger API Server evaluates the command against its local view, including the resolution of key lookups (`lookupByKey` and `fetchByKey`). Submitted commands are evaluated in parallel, both on a single node and across different nodes.

The evaluated command is then sent to the sync service, which runs Canton's [commit protocol](#). The protocol provides a linear ordering of all transactions on a single sync domain, and participants check all transactions for conflicts, with an earlier-transaction-wins policy. As participants only see parts of transactions (the joint [projection](#) of the parties they host), they only check conflicts on contracts for which they host stakeholders. During conflict detection, positive key lookups (that find a contract ID based on a key) are treated as ordinary `fetch` commands on the found contract ID, and the contract ID is checked to still be active. Negative key lookups, on the other hand, are never checked by Canton (a malicious submitter, for example, can always successfully claim that the lookup was negative). Similarly, contract creations are not checked for duplicate keys. Logically, both of these checks would require checking a `there is no such key` statement. Canton does not check such statements. While adding the check to the individual participants is straightforward, it is hard to get meaningful guarantees from such local checks because each participant has only a limited view of the entire virtual global ledger. For example, the check could pass locally on a participant even though there exists a contract with the given key on some sync domain that the participant is not connected to. Similarly, since the processing of different sync domains runs in parallel, it is unclear how to consistently handle the case where transactions on different sync domains create two contracts with the same key.

For integrity, the participants also re-evaluate the submitted command (or, more precisely, the sub-transaction in the joint [projection](#) of the parties they host). The commit protocol ensures that any two involved participants will evaluate the key lookups in the same way as the Ledger API Server of the submitting participant. That is, if there are two active contracts with the key `k`, the protocol ensures that a `fetchByKey k` will return the same contract on all participants.

Once the sync protocol commits a transaction, it informs the Ledger API server, which then atomically updates its set of active contracts. The transactions are passed to the Ledger API server in the order

in which they are recorded on the ledger.

Workarounds for Recovering Uniqueness

Since some form of uniqueness for ledger data is necessary in many cases, we list some strategies to achieve it in Canton without being locked into a UCK sync domain. The strategies' applicability depends on your contracts and the deployment setup of your application. In general, none of the strategies apply to the case where creations and deletions of contracts with keys are delegated.

Setting: Single Maintainer, Single Participant Node

Often, contracts may have a single maintainer (e.g., an `operator` that wants to have unique user names for its users). In the simplest case, the maintainer party will be hosted on just one participant node. This setting allows some simple options for recovering uniqueness.

Command ID Deduplication

The Ledger API server deduplicates commands based on their IDs. Note, however, that the IDs are deduplicated only within a configured window of time. This can simplify the uniqueness bookkeeping of your application as follows. Before your application sends a command that creates a contract with the key `k`, it should first check that no contract with the key `k` exists in a recent ACS snapshot (obtained from the Ledger API). Then, it should use a command ID that is a deterministic function of `k` to send the command. This protects you from the race condition of creating the key twice concurrently, without having to keep track of commands in flight. Caveats to keep in mind are:

- you need to know exactly which contracts with keys each of your commands will create
- your commands may only create contracts with a single key `k`
- only the maintainer party may submit commands that create contracts with keys (i.e., do not delegate the creation to other parties).

However, these conditions are often true in simple cases (e.g., commands that create new users).

Generator Contract

Another approach is to funnel all creations of the keyed contracts through a `generator` contract. An example generator for the `Keyed` template is shown below.

```
template Generator
  with
    sig: Party
  where
    signatory sig

    choice Generate : (ContractId Generator, ContractId Keyed)
      with
        k: Int
      controller sig
      do
        existing <- lookupByKey @Keyed (sig, k)
```

(continues on next page)

(continued from previous page)

```

keyed <- case existing of
  Some cid -> pure cid
  None ->
    create Keyed with ..
gen <- create this
pure (gen, keyed)

```

The main difference from the `Orchestrator` contract is that the `Generate` choice is consuming. Caveats to keep in mind are:

Your application must ensure that you only ever create one `Generator` contract (e.g., by creating one when initializing the application for the first time).

All commands that create the `Keyed` contract must be issued by the maintainer. In particular, do not delegate choices on the `Generator` contract to other parties, because those parties may not have full visibility into all the `Keyed` contracts and `lookupByKey` may therefore wrongly return `None`.

You must not create `Keyed` contracts by any other means other than exercising the `Generate` choice.

The `Generate` choice as shown above will not abort the command if the contract with the given key already exists, it will just return the existing contract. However, this is easy to change.

This approach relies on a particular internal behavior of Canton (as discussed below). While we don't expect the behavior to change, we do not currently make strong guarantees that it will not change.

If the participant is connected to multiple sync domains in future versions of Canton, the `Generator` contract cannot guarantee uniqueness, as explained below. To be future-proof, you should only use the `Generator` approach in settings when your participant is connected to a single sync domain.

A usage example script is below.

```

generator = script do
  alice <- allocateParty "Alice"
  -- Your application must ensure that the following command runs at most once
  gen <- submit alice $
    createCmd Generator with sig = alice
  (gen, keyed) <- submit alice $
    exerciseCmd gen Generate with k = 1
  (gen, keyed1) <- submit alice $
    exerciseCmd gen Generate with k = 1
  assert $ keyed1 == keyed
  submit alice $
    exerciseCmd keyed Archive
  (gen, keyed2) <- submit alice $
    exerciseCmd gen Generate with k = 1
  assert $ keyed2 /= keyed

```

To understand why this works, first read how keys are [implemented in Canton](#). With this in mind, since the `Generate` choice is consuming, if you issue two or more concurrent commands that use the `Generate` choice, at most one of them will succeed (as the `Generator` contract will be archived when the first transaction commits). Thus, all accepted commands will be evaluated sequentially by the Ledger API server. As the server writes the results of accepted commands to its database atomically, the `Keyed` contract created by one command that uses `Generate` will either be visible to the following command that uses `Generate`, or it will have been archived by some other, unrelated command in between.

If the participant is connected to multiple sync domains, the `Generator` contract can be reassigned between those sync domains. Around such reassignments, it can happen that the Ledger API server already starts processing a command on the target sync domain before it has completely processed everything prior to the reassignment on the source sync domain. The processing on the target sync domain does not necessarily see all key `Keyed` contracts created by predecessors of the current `Generator` contract, and therefore may create contracts with the same key multiple times.

Setting: Single Maintainer, Multiple Participants

Ensuring uniqueness with multiple participants is more complicated, and adds more restrictions on how you operate on the contract.

When there is a single maintainer hosted on multiple participant nodes, the `Generator` approach works only under the following additional restriction:

The `Generator` contract is never used with explicit disclosure for the following reasons:

The correctness argument is now more complicated than in the single-participant setting: Since the `Generate` choice is consuming and there is at most one `Generator` contract at any time, the `Generator` contract evolves sequentially, where the order is determined by the single sync domain that orders the `Generate` commands. However, the `lookupByKey` operation is evaluated locally on the participant nodes possibly in a different order. Without explicit disclosure, a command can successfully exercise a choice on a `Generator` contract only after the submitting participant has processed the transaction that created the `Generator` contract, because the participant must fetch the `Generator` contract from its database. So if the `Generator` contract is still active when the command is ordered on the sync domain, no other `Keyed` contract was created in the meantime and a negative `lookupByKey` is correct. Together with atomic database updates for transaction processing, uniqueness is therefore guaranteed. This argument breaks when the `Generator` contract is explicitly disclosed: then the participant node can exercise a choice on a `Generator` contract before it has processed the transaction that creates it.

In the single-participant setting, explicit disclosure is not a problem because the explicit disclosure can only be obtained via the Ledger API of the single participant that also submits the next command. The participant thus has processed the creating transaction already and sees the created `Keyed` contracts.

Another approach is to track all allocations and deallocations of a key through a helper contract.

```
template KeyState
  with
    sig: Party
    k: Int
    allocated: Bool
  where
    signatory sig

    choice Allocate : (ContractId KeyState, ContractId Keyed)
      controller sig
      do
        assert $ not allocated
        newState <- create this with allocated = True
        keyed <- create Keyed with ..
        pure (newState, keyed)
```

(continues on next page)

(continued from previous page)

```

choice Deallocate : ContractId KeyState
  controller sig
    do
      assert $ allocated
      (cid, _) <- fetchByKey @Keyed (sig, k)
      exercise cid Archive
      create this with allocated = False

```

Caveats:

Before creating a contract with the key `k` for the first time, your application must create the matching `KeyState` contract with `allocated` set to `False`. Such a contract must be created at most once. In most cases, you should choose a primary participant on which you create such contracts.

With a small number of exceptions, `Keyed` contracts must never be created or archived directly; this would break the synchronization with the corresponding `KeyState` contract. Instead, you must use the `Allocate` and `Deallocate` choices on the `KeyState` contract. The following exceptions are fine because Daml transactions execute atomically:

- A consuming choice on the `Keyed` contract that immediately recreate a `Keyed` contract with the same key.
- Ledger API commands that archive a `Keyed` contract and recreate a `Keyed` contract with the same key.

Do not delegate consuming choices on the `Keyed` contract other than those that immediately recreate a `Keyed` contract with the same key. Instead, delegate appropriate adaptations of `Deallocate` on the corresponding `KeyState` contract. This ensures the above restriction that `Keyed` contracts are created and archived only through the `KeyState` contract choices. Non-consuming choices on `Keyed` contracts can be delegated without restrictions, and so can all the choices on `KeyState`.

A usage example script is below.

```

state = script do
  alice <- allocateParty "Alice"
  -- Your application must ensure that the following command executes at most once
  state <- submit alice $
    createCmd KeyState with sig = alice, k = 1, allocated = False
  (state, keyed) <- submit alice $
    exerciseCmd state Allocate
  submitMustFail alice $
    exerciseCmd state Allocate
  -- If you archive the keyed contract without going through the
  -- KeyState, you must also recreate it in the same transaction.
  -- For example, if Keyed had consuming choices, the choices' bodies
  -- would have to recreate another Keyed contract with the same key
  submit alice $ do
    exerciseCmd keyed Archive
    createCmd Keyed with sig = alice, k = 1
    pure ()
  state <- submit alice $
    exerciseCmd state Deallocate
  (state, keyed2) <- submit alice $
    exerciseCmd state Allocate
  assert $ keyed2 /= keyed

```

The `KeyState` approach also works in the single maintainer, single participant setting.

An alternative to this approach, if you want to use a consuming choice `ch` on the `Keyed` template that doesn't recreate key, is to record the contract ID of the `KeyState` contract in the `Keyed` contract. You can then call `Deallocate` from `ch`, but you must first modify `Deallocate` to not perform a `lookupByKey`.

Setting: Multiple Maintainers

Achieving uniqueness for contracts with multiple maintainers is more difficult, and the maintainers must trust each other. To handle this case, follow the `KeyState` approach from the previous section. The main difference is that the `KeyState` contracts must have multiple signatories. Thus you must follow the usual Daml pattern of collecting signatories. Be aware that you must still structure this such that you only ever create one `KeyState` contract.

Formal Semantics of Keys in Canton

In terms of the [Daml ledger model](#), Canton's virtual shared ledger satisfies key consistency only when it represents a single UCK sync domain. In general, Canton's virtual shared ledger violates key consistency. That is, `NoSuchKey k` actions may happen on the ledger even when there exists an active contract with the key `k`. Similarly, `Create` actions for a contract with the key `k` may appear on the ledger even if another active contract with the key `k` exists.

In terms of Daml evaluation, i.e., the translation of Daml into the ledger model transactions, the following changes:

When evaluated against an active contract set, a `fetchByKey k` may result in a `Fetch c` action for any active contract `c` with the key `k` (in Canton, there can be multiple such contracts). In the current implementation, it will favor the most recently created contract within the single transaction. However, this is not guaranteed to hold in future versions of Canton. If no contract with key `k` is active, it will fail as usual.

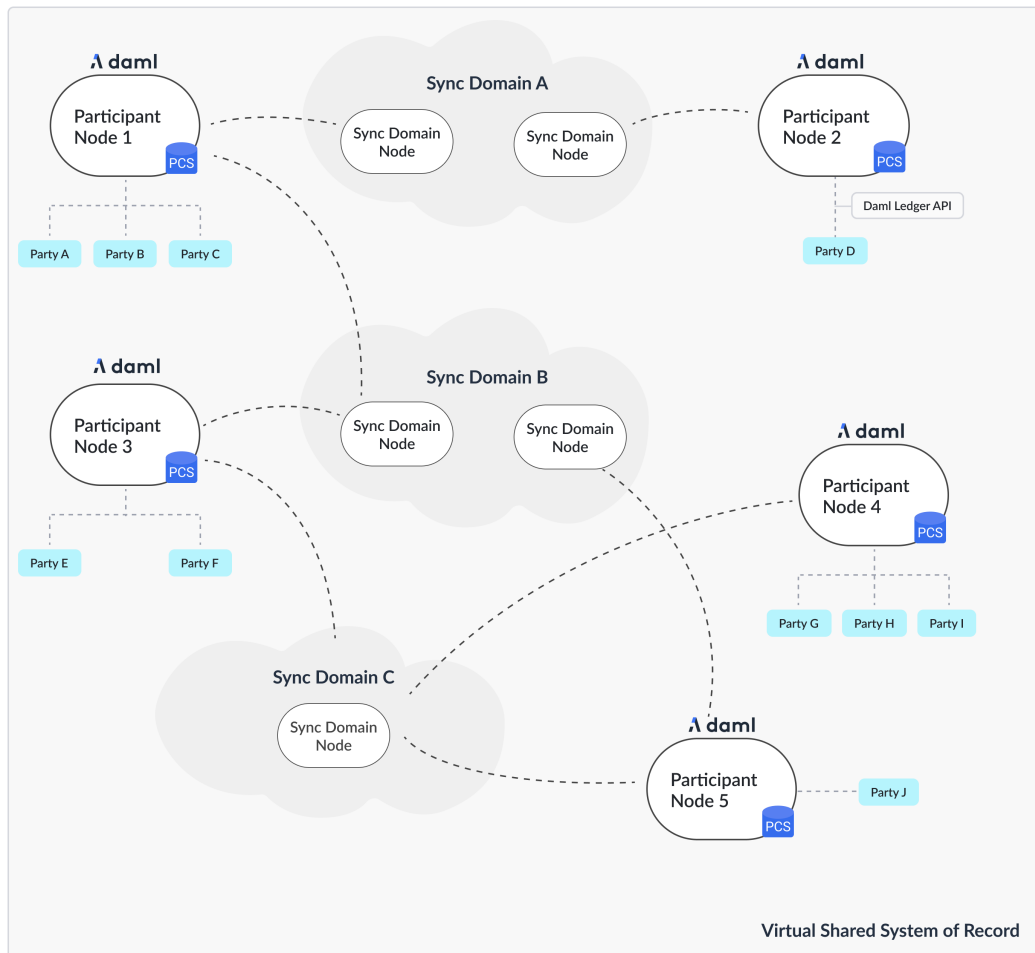

Similarly, `lookupByKey k` may result in a `Fetch c` for any active contract `c` with the key `k` of which the submitter is a stakeholder. If no such contract exists, it results in a `NoSuchKey k` as usual.

Likewise, an `exerciseByKey k` may result in an `Exercise` on any contract `c` with the key `k`. It fails if no contract with key `k` is active.

46.2.2 Synchronization Domain Architecture and Integrations

Recall the high-level topology with Canton sync domain being backed by different technologies, such as a relational database as well as block-chains like Hyperledger Fabric or Ethereum.

In this chapter, we define the requirements specific to a Canton sync domain, explain the generic sync domain architecture, as well as the concrete integrations for Canton sync domain.

46.2.2.1 Synchronization Domain-Specific Requirements

The [high-level requirements](#) define requirements for Canton in general, covering both participants and sync domains. This section categorizes and expands on these high-level requirements and defines sync domain-specific requirements, both functional and non-functional ones.

Functional Requirements

The sync domain contributes to the high-level functional requirements in terms of facilitating the synchronization of changes. As the sync domain can only see encrypted transactions, refer to transaction privacy in the non-functional requirements, the functional requirements are satisfied on a lower level than the Daml transaction.

Synchronization: The sync domain must facilitate the synchronization of the shared ledger among participants by establishing a total order of transactions.

Transparency: The sync domain must inform the designated participants of changes to the shared ledger in a timely manner.

Finality: The sync domain must facilitate the synchronization of the shared ledger in an append-only fashion.

No unnecessary rejections: The sync domain should minimize unnecessary rejections of valid transactions.

Seek support for notifications: The sync domain must facilitate offset-based access to the notifications of the shared ledger.

Non-Functional Requirements

Reliability

Seamless fail-over for sync domain entities: All sync domain entities must be able to tolerate crash faults up to a certain failure rate, e.g., one sequencer node out of three can fail without interruption.

Resilience to faulty sync domain behavior: The sync domain must be able to detect and recover from failures of the sync domain entities, such as performing a fail-over on crash failures or retrying operations on transient failures if possible. The sync domain should tolerate byzantine failures of the sync domain entities.

Backups: The state of the sync domain entities must be backed up such that in case of disaster recovery, only a minimal amount of data is lost.

Site-wide disaster recovery: In case of a failure of a data-center hosting a sync domain, the system must be able to fail over to another data center and recover operations.

Resilience to erroneous behavior: The sync domain must be resilient to erroneous behavior from the participants interacting with it.

Scalability

Horizontal scalability: The parallelizable sync domain entities and their sub-components must be able to horizontally scale.

Large transaction support: The sync domain entities must be able to cope with large transactions and their resulting large payloads.

Security

Sync domain entity compromise recovery: In case of a compromise of a sync domain entity, the sync domain must provide procedures to mitigate the impact of the compromise and allow to restore operations.

Standards compliant cryptography: All used cryptographic primitives and their configurations must comply with approved standards and be based on existing and audited implementations.

Authentication and authorization: The participants interacting with the sync domain as well as the sync domain entities internal to the sync domain must authenticate themselves and have their appropriate permissions enforced.

Secure channel (TLS): All communication channels between the participants and the sync domain as well as between the sync domain entities themselves have to support a secure channel option using TLS, optionally with client certificate-based mutual authentication.

Distributed Trust: The sync domain should be able to be operated by a consortium to distribute the trust of the participants in the sync domain among many organizations.

Transaction Metadata Privacy: The sync domain entities must never learn the content of the transactions. The sync domain entities should learn a limited amount of transaction metadata, such as structural properties of a transaction and involved stakeholders.

Manageability

Garbage collection: The sync domain entities must provide ways to minimize the amount of data kept on hot storage. In particular, data that is only required for auditability can move to cold storage or data that has been processed and stored by the participants could be removed after a specific retention period.

Upgradeability: The sync domain as a whole or individual sync domain entities must be able to upgrade with minimal downtime.

Semantic versioning: The interfaces, protocols, and persistent data schemas of the sync domain entities must be versioned according to semantic versioning guidelines.

Sync domain-approved protocol versions: The sync domain must offer and verify the supported versions for the participants. The sync domain must further ensure that the sync domain entities operate on compatible versions.

Reuse off-the-shelf solutions: The sync domain entities should use off-the-shelf solutions for persistence, API specification, logging, and metrics.

Metrics on communication and processing: The sync domain entities must expose metrics on communication and processing to facilitate operations and trouble shooting.

Component health monitoring: The sync domain entities must expose a health endpoint for monitoring.

46.2.2.2 Synchronization Domain-Internal Components

The following diagram shows the architecture and components of a Canton sync domain as well as how a participant node interacts with the sync domain.

The sync domain consists of the following components:

Sync Domain Service: The first point of contact for a participant node when connecting to a sync domain. The participant performs a version handshake with the sync domain service and discovers the available other services, such as the sequencer. If the sync domain requires a service agreement to be accepted by connecting participants, the sync domain service provides the agreement.

Sync Domain Topology Service: The sync domain topology service is responsible for all topology management operations on a sync domain. The service provides the essential topology state to a new participant node, that is, the set of keys for the sync domain entities to bootstrap the participant node. Furthermore, participant nodes can upload their own topology transactions to the sync domain topology service, which inspects and possibly approves and publishes those topology transactions on the sync domain via the sequencer.

Sequencer Authentication Service: A node can authenticate itself to the sequencer service either using a client certificate or using an authentication token. The sequencer authentication service issues such authentication tokens after performing a challenge-response protocol with the node. The node has to sign the challenge with its private key corresponding to a public key that has been approved and published by the sync domain identity service.

Sequencer Service: The sequencer service establishes the total order of messages, including transactions, within a sync domain. The service implements a total-order multicast, i.e., the sender of a message indicates the set of recipients to which the message is delivered. The order is established based on a unique timestamp assigned by the sequencer to each message.

Sequencer Manager: The sequencer manager is responsible for initializing the sequencer service.

Mediator: The mediator participates in the Canton transaction protocol and acts as the transaction commit coordinator to register new transaction requests and finalizes those requests by collecting transaction confirmations. The mediator provides privacy among the set of transaction stakeholders as the stakeholders do not communicate directly but always via the mediator.

The sync domain operator is responsible for operating the sync domain infrastructure and (optionally) also verifies and approves topology transactions, in particular to admit new participant nodes to a sync domain. The operator can either be a single entity managing the entire sync domain or a consortium of operators, refer to the distributed trust security requirement.

46.2.2.3 Drivers

Based on the set of sync domain internal components, a driver implements one or more components based on a particular technology. The prime component is the sequencer service and its ordering functionality, with implementations ranging from a relational database to a distributed blockchain. Components can be shared among integrations, for example, a mediator implemented on a relational database can be used together with a blockchain-based sequencer.

46.2.2.4 Canton Synchronization Domain on Ethereum

A Canton Ethereum sync domain uses a sequencer backed by Ethereum instead of by another ledger (such as Postgres or Fabric). The other sync domain components (mediator, sync domain manager) are reused from the relational database driver. Architecturally, the Canton Ethereum sequencer is a JVM application that interacts with an Ethereum client via the [RPC JSON API](#) to write events to the blockchain. Specifically, it interacts with an instance of the smart contract `Sequencer.sol` and calls function of `Sequencer.sol` to persist transactions and requests to the blockchain. It uses the configured Ethereum account to execute these calls. Analogous to the database-based sequencer implementations, multiple Ethereum sequencer applications can read and write to the same `Sequencer.sol` smart contract instance and they can do so through different Ethereum client nodes for high availability, scalability, and trust. The following diagram shows the architecture of an Ethereum-based sync domain:

Note: When running in a multi-writer setup, each Ethereum Sequencer application needs to use a separate Ethereum account. Otherwise, transactions may get stuck due to nonce mismatches.

Smart contract `Sequencer.sol`

The smart contract deployed to the blockchain is implemented in Solidity. Its latest revision `drivers/ethereum/solidity/Sequencer.sol` is available in the enterprise edition only.

Data is written to the blockchain by emitting [events](#) to the transaction logs. The Sequencer Application reads all transactions (and transaction logs) created from calls to `Sequencer.sol` and keeps its own store for a view of the sequencer history. This enables the Sequencer Application to serve read subscriptions promptly without having to query the Ethereum client and to restart without having

to re-read all the history. The store can either use in-memory storage or persistent storage (using a database).

46.2.2.5 Canton Synchronization Domain on Fabric

Introduction to Hyperledger Fabric

[Hyperledger Fabric](#) is an open source enterprise-grade permissioned distributed ledger technology (DLT) platform.

Components of the Fabric Blockchain Network

The following key concepts of Fabric are relevant for the Canton sync domain integration with Fabric. For further details, refer to the [Fabric documentation](#).

Peers: A network entity that maintains a Fabric ledger and runs chaincode containers to perform read/write operations to the Fabric ledger. Peers are owned and maintained by organizations.

Channels: A channel is a private blockchain overlay that allows for data isolation and confidentiality. A channel-specific Fabric ledger is shared across the peers in the channel, and transacting parties must be authenticated to a channel to interact with it. Members who are not a part of the channel are unable to see the transactions or even know that the channel exists.

Ordering Service: Also known as orderer. A defined collective of nodes that orders transactions into a block and then distributes blocks to connected peers for validation and commitment. The ordering service exists independently of the peer processes and orders transactions on a first-come-first-serve basis for all channels on the network.

Chaincode: A smart contract is code – invoked by a client application external to the blockchain network – that manages access and modifications to the current Fabric ledger state via trans-

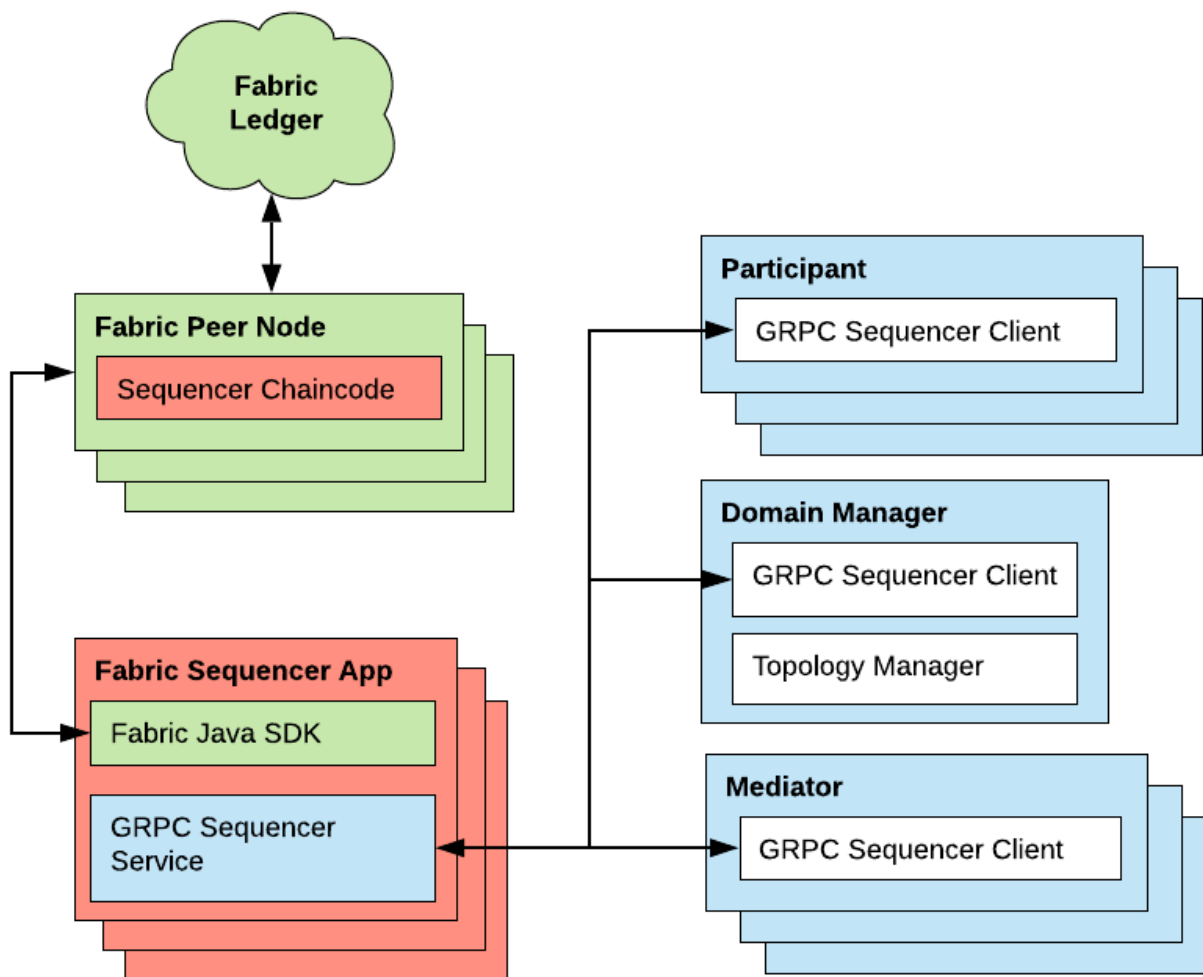

Fig. 14: An example Fabric blockchain network with four organizations. The ordering service has ordering nodes for ordering and distributing blocks on each of the channels defined under the ordering service. Channel A includes all four organizations, while channel B includes only Org 3 and Org 4. Authenticated client applications can send calls to their associated peers on the network.

actions. In Hyperledger Fabric, smart contracts are packaged as chaincode. Chaincode is installed on peers and then defined and used on one or more channels. An endorsement policy specifies for each instantiation of a chaincode which peers have to validate and endorse a transaction, such that the transaction is considered valid and part of the Fabric ledger.

Applications: Client applications in a Fabric-based network interact with the Fabric ledger using one of the available Fabric SDKs. Applications can propose changes to the ledger as well as query the state of the ledger by using an identity issued by the organization's certificate authority (CA).

Architecture

In the v1 architecture of the Fabric driver, only the sequencer is integrated on top of Fabric. The other sync domain components are reused from the relational database driver. The Fabric-based sequencer supports running in a multi-writer, multi-reader topology for high availability, scalability, and trust. The following diagram shows the architecture of a Fabric-based sync domain integration.

Fabric-based Sequencer

The Fabric Sequencer Application serves as an external standalone sequencer application that participants and other sync domain entities in a Canton network connect to in order to exchange ordered messages. It is an application that runs over Fabric by a consortium of organizations.

Typically each app operates via one Fabric client that belongs to a specific organization. These Fabric peers have visibility of the sequencer messages' metadata (sender and recipients of the messages), however the messages' payloads are fully encrypted.

A Canton sync domain requires, in addition to the sequencers, one sync domain manager and one or more independently operated mediators. All these nodes exclusively communicate with participants via the sequencer.

Participants trust the app they connect to and they can specify which one to connect to among the available ones. Participants could verify that Sequencer Applications are reporting consistent information by connecting to many or periodically checking other apps as they all need to report the same data.

The application supports a multi-writer, multi-reader architecture, such that multiple Fabric applications can operate on top of the same Fabric ledger. Sequencer clients within the participants, sync domain manager, or mediators will communicate with the Sequencer Fabric Application and they can read or write from any of the available sequencer apps as they will have a shared view of the Sequencer history for the sync domain.

Additionally, the same Fabric setup with a different channel can be used to operate different synchronizers on the same Fabric infrastructure, since each channel contains a separate isolated Fabric ledger.

Sequencer Chaincode

The chaincode is implemented in Go. It supports:

- Registering new members with the sequencer

- Sending messages over the sequencer

- the messages are ordered by the Fabric ordering service and we subsequently use that order to define counters and timestamps
 - if instead the order were defined in chaincode by keeping track of the last message counter, congestion would be created because the application would either have to process one message at a time or create a mechanism of batching messages to be processed in one transaction

The Sequencer Application reads all transactions created from chaincode operations and keeps its own store for a view of the sequencer history enabling them to serve read subscriptions promptly without having to constantly query chaincode and to restart without having to re-read all the history.

Analysis and Limitations

Below is an analysis of driver requirements (functional and non-functional).

Functional Requirements

The Fabric driver must satisfy the following functional requirements:

Synchronization Fabric's ordering service establishes a total-order of transactions within a channel. A Canton sync domain is based on a single channel.

Transparency The Fabric blockchain ensures that all sequencer nodes obtain the same set of messages in the same order as established by the ordering service. The sequencer nodes inform their connected clients about their designated messages where the client is a recipient on.

Finality Fabric's ordering service provides finality, i.e., there will be no ledger forks and validated transactions will never be reverted.

Seek support for notifications The Fabric blockchain retains all sent messages and notifications. For efficiency purposes, the sequencer node caches the messages to satisfy read operations for a given offset without fetching the corresponding block.

Performance

The current performance we observe with the Fabric integration is around 15 tps of throughput and average latency of 800ms. Those numbers are based on local performance tests using the Daml Ledger API test tool with a simple 2 organizations with 1 peer each and 1 orderer node topology and a 2 of 2 endorsement policy.

Some factors that positively contribute to the current performance are:

- Using Java for the SDK and Go for chaincode are good choices as opposed to something like Javascript for being compiled languages

- We added more memory (2GB) to each peer and orderer node in our setup, which showed considerable performance improvement

- The simplicity of the setup (only 2 peers, one orderer and all local)

- Transactions are usually very small

- Chaincode implementation is very simple

- Some experiments were conducted with block cutting parameters such as max message count (max number of transactions that can exist in a block before a new block is cut) and batch timeout (max amount of time to wait before creating a block) in order to find a good balance of throughput and latency for our applications. A good tradeoff was found at 50 for max message count and 200ms for batch timeout, with an improvement for throughput at a slight increase in latency.

- We are using LevelDB (instead of CouchDB).

- We are using a round-robin load balancer when connecting to multiple sequencers and using the both sequencers' health and connectivity as a failover criteria.

[This paper by IBM Research, India](#) and [this article by IBM](#) discuss the many factors that can influence performance. [This blog post](#) also shares some Fabric performance best practices.

Reliability

Seamless fail-over for sync domain entities The sequencer can be deployed in a multi-writer and multi-reader topology (i.e. multiple sequencer nodes for the same sync domain) to achieve high availability. Since all Fabric sequencer nodes run on top of the same Fabric ledger, they will all see the same data and does not matter which sequencer is being used to write to and read from.

Additionally, the Fabric sequencer node is backed by a database that caches the data read from the Fabric ledger such that in case of a crash it does not have to read the whole blockchain again. It just needs to start reading the blocks from where it last processed. The app also supports crash recovery.

On the client side, round-robin load balancing is used such that if one of the sequencer nodes goes down or becomes unhealthy clients will not route any requests to this sequencer. The sequencer provides a health endpoint that is used by clients for this purpose. It will indicate that it is unhealthy if it loses connection to the Fabric ledger or to its database.

Both the mediator and sync domain manager are also highly available via an active/passive mechanism (one active instance and 1-N passive replicas).

Resilience to faulty sync domain behavior Although Fabric supports for pluggable consensus protocols such as crash fault-tolerant (CFT) or byzantine fault tolerant (BFT) protocols that enable the platform to be customized to fit particular use cases and trust models, at the moment Fabric only offers a CFT ordering service implementation based on the Raft protocol.

Backups The backup procedures of the Fabric ledger must be used. The state of the sequencer node is just a cache and can be rehydrated from the state of the ledger.

Site-wide disaster recovery In a multi-writer, multi-reader topology, the sequencer nodes can be hosted by different organizations and across multiple data centers to recover from the failure of an entire data center.

Resilience to erroneous behavior The Fabric sequencer node offers some resilience against an erroneous participant. For example, it checks that a client does not send messages to invalid recipients and only allows registered and authenticated clients to send messages. Clients are also required to sign their messages so sequencers can verify their origin, which prevents malicious sequencers from creating fake messages on behalf of specific members.

Scalability

Horizontal scalability Adding a sequencer to a sync domain is simply a matter of creating a new Fabric user and a new sequencer application with that configuration. A new Fabric organization and more Fabric peers could also be created, but this is optional. The setup scales horizontally as well as a Fabric ledger, which means performance could suffer if the Fabric topology is made more complex by adding peers and orderer nodes, in particular if their latency to each other is high. But there are ways to make up for that such as using a simpler endorsement policy that does not include all organizations in the setup. That's a trade-off between performance and trust that needs to be defined by the consortium.

Large transaction support Some Fabric platforms have a limit on the size of the block (commonly 99MB). This is therefore a hard limit that this sequencer has on the size of the transactions.

Security

Sync domain entity compromise recovery Without BFT support, a compromised orderer node cannot be recovered from automatically. Operational procedures, such as revoking the node's certificate, can limit further impact. Additionally, compromised peer nodes could endorse invalid transactions, but it would take a number of compromised peers enough to satisfy the endorsement policy to create incorrectly endorsed transactions on the ledger. All sequencer nodes must provide the same stream of messages, thus a compromised and malicious sequencer node can be detected if their stream differs.

Standards compliant cryptography The sequencer node and the other Canton sync domain entities use standard modern cryptography (EC-DSA with NIST curves and Ed25519 for signatures, AES128 GCM for symmetric encryption, SHA256 for hashes) provided by Tink/BouncyCastle. Fabric nodes can be deployed using cryptography provided by an [HSM](#).

Authentication and authorization Authentication is implemented such that any sequencer client needs to be registered by the topology manager before they can connect. There are also authorization checks such as making sure that the declared sender is the currently authenticated client. Based on the type of member that is authenticated there are certain operations that may or may not be allowed.

Secure channel (TLS) The sequencer node provides an API secured with TLS. The Fabric network should be deployed according to its operations guide with TLS.

Distributed Trust A Fabric network can be operated by multiple organizations forming a consortium and distributing the trust among the organizations. The mediator(s) and sync domain manager can only be operated by a single entity, so there is no distribution of trust for these nodes.

Transaction Metadata Privacy The sequencer node and the Fabric nodes (peers, orderer) learn the metadata of the transaction, in particular the stakeholders involved in the transaction.

Manageability

Garbage collection As Fabric is based on an immutable blockchain, processed sequencer messages cannot be removed. However there is a preview feature that allows messages to be removed by storing them in private data collections (which can be purged).

Upgradeability Upgrades of individual sync domain entities with minimal downtime not yet implemented.

Semantic versioning Canton is released under semantic versioning. The sequencer gRPC API is versioned with a major version number.

Sync domain approved protocol versions The authentication protocol validates the version compatibility between the sequencer nodes and the connecting node.

Reuse off-the-shelf solutions The local state of the sequencer node is stored in a relational database (Postgres).

Metrics on communication and processing Metrics are not yet fully implemented.

Component health monitoring The sequencer node contains basic health monitoring as an admin command.

46.2.3 Identity Management

46.2.3.1 Identity Providing Service

Every sync domain requires a shared and synchronized knowledge of identities and their associated keys among all participants and sync domain entities as the synchronization protocol is built with the principle that provided the same data, all validators must come verifiably to the same result.

The service that establishes this shared understanding in a sync domain is the *Identity Providing Service (IPS)*. From a synchronization protocol perspective, the IPS is an abstract component and the synchronization protocol only ever interacts with the read API of the IPS. There is no assumption on how the IPS is implemented, only the data it provides is relevant from a synchronization perspective.

The participant nodes, the sequencer and the mediator have a local component called the *Identity Providing Service Client (IPS client)*. This component establishes the connection to the IPS of the sync domain to read and validate the identity information in the sync domain.

The IPS client exposes a read API providing aggregated access to the sync domain topology information and public keys provided by the IPS of one or more sync domains.

The identity-providing service receives keys and certificates through some process and evaluates the justifications, before presenting the information to the IPS clients of the participant or sync domain entities. The IPS clients verify the information. The local consumers of the IPS client-read API trust the provided information without verifying the justifications, leading to a separation of synchronization and identity management.

Requirements

The identity-providing service describes the interface between the identity management process and the synchronization functionality. It satisfies the high-level platform requirement on [identity information updates](#). The following requirements are written from the perspective of the IPS client, i.e., the synchronization layer components.

Mapping of Parties to Participants. I can query the state at a certain time and subscribe to a stream of updates associating a known identifier of a party to a set of participants as well as the local participant to a set of hosted parties. Mapping to a set of participants satisfies the high-level requirement on [parties using multiple participants](#).

Participant Qualification. I can query the state at a certain time and subscribe to a stream of updates informing me about the trust level of a participant indicating either *untrusted* (trust level of 0) or *trusted* (trust level of 1).

Participant Relationship Qualification. A party-to-participant relationship is qualified, restricted to submission (including confirmation), confirmation, or observation (read-only). This also satisfies the high-level requirement on [read-only participants](#).

Sync-Domain-Aware Mapping of Participants to Keys. I can query the state at a certain time and subscribe to a stream of updates mapping participants to a set of keys per sync domain.

Sync Domain Entity Keys. I can query the current state and subscribe to a stream of updates on the keys of the sync domain entities.

Lifetime and Purpose of Keys. I can learn, for any key that I receive, what it is used for, what cryptographic protocol it refers to, and when it expires.

Signature Checking. Given a blob, a key I obtained from the IPS and a signature, I can verify that the signature is a valid signature for the given blob, signed with the respective key at a certain time.

Immutability. The history of all keys is preserved within the same time boundaries as my audit logs such that I can always audit my participant or sync domain entity logs.

Evidence. For any data which I receive from the IPS I can get the set of associated evidence such that I can prove my arguments in a legal dispute. The associated evidence contains a descriptor that I can use to read up in the documentation on the definition of the otherwise opaque blob.

Race Condition Free. I can be sure that I am always certain about the validity of a key with respect to a transaction such that there cannot be a disagreement on the validity of a transaction due to an in-flight key change.

Querying for Parties. I can query, using an opaque query statement, the IPS for a party and will receive results based on a privacy policy not known to me.

Party metadata. I can access metadata associated with a party for display purposes.

Equivalent Trust Assumptions A federation protocol of the reference identity management service needs to be based on equivalent trust assumptions as the interoperability protocol such that there is no mismatch between the capabilities of the two.

Associated requirements that extend beyond the scope of the IPS:

API Versioning. I can use a versioned API that supports further extensions, see our general principles of upgradability and Software Versioning.

GDPR compliance. The identity-providing service needs to comply with regulatory requirements such as the GRPR right to be forgotten.

Composability. The identity providing service needs to be composable such that I can add my own identity providing service based on the documentation and released binary artifacts.

46.2.3.2 Identity Management Design

While the previous section introduced the IPS as an abstract concept, we describe here the concrete implementation of our globally composable topology management system which incorporates identity. The design is introduced by first calling out a few basic design principles. We then introduce a formalism for the necessary topology management transactions. Finally, we connect the formalism to actual processes and cryptographic artifacts that describe the concrete implementation.

Design Principles

To understand the approach, a few key principles need to be introduced.

The synchronization protocol is separated from the topology protocol. However, to leverage the composability properties of the synchronization protocol, an equivalent approach is required for topology transactions. As such, given that there is no single globally trusted entity we can rely on for synchronization, we also can't rely on a single globally trusted entity to establish identities, which leads us to the first principle:

Principle 1: For global synchronization to work in reality, there cannot be a single trust anchor.

A cryptographic key pair can uniquely be identified through the fingerprint of the public key. By owning the associated private key, an entity can always prove unambiguously through a signature that the entity is the owner of the public key. We are using this principle heavily in our system to verify and authorize the activities of the participants. As such, we can introduce the second principle:

Principle 2: A participant is someone who can authorize and whose authorizations can be verified (someone with a known key)

In short, a participant is someone with a key or with a set of keys that are known to belong together. However, the above definition doesn't mean that we necessarily know who owns the key. Ownership is an abstract aspect of the real world and is not relevant for the synchronization itself. Real-world ownership is only relevant for the interpretation of the meaning of some shared data, but not of the data processing itself.

Therefore, we introduce the third principle:

Principle 3: We separate the certification of system identities and legal identities (or separation of cryptographical identity and metadata)

Using keys, we can build trust chains by having a key sign a certificate certifying some ownership or some fact to be associated with another key. However, at the root of such chains is always the root key. The root key itself is not certified and the legal ownership cannot be verified: we just need to believe it. As an example, if we look at our local certificate store on our device, then we just believe that a certain root is owned by a named certificate authority. Our belief is rooted in the trust in our operating system provider that they have included only legitimate keys.

As such, any link between legal identities to cryptographic keys through certificates is based on a belief that the entity controlling the root key is honest and ensures that everybody attached to the trust root has been appropriately vetted. Therefore, we can only believe that legal identities are properly associated, but verifying it in the absolute sense is very difficult, especially impossible online.

Another relevant aspect is that identity requirements are asymmetrical properties. While large corporations want to be known by their name (BANK), individuals tend to be more closed and would prefer that their identity is only revealed if necessary (GDPR, HIPAA, confidential information, bank secrecy). Also, by looking at a bearer bond, for example, the owner has a much higher interest in the identity of the obligor than the obligor has in the owner. If the obligor turns out to be bad or a fraud, the owner might lose all their money. In contrast, the obligor does not care to whom they are paying back the bond, except for some regulatory reasons. Therefore, we conclude the fourth principle

Principle 4: Identities on the ledger are an asymmetric problem, where privacy and publicity need to be carefully weighed on a case-by-case basis.

Formalism for a Global Composeable Topology System

Definitions

To construct a global composable topology system that incorporates identity, we introduce a topology scheme leading to globally unique identifiers. This allows us to avoid federation, which would require cooperation between identity providers or consensus among all participants and would be difficult to integrate with the synchronisation protocol.

We use (p_k^x, s_k^x) to refer to a public/private key pair of some cryptographic scheme, where the super-script x will provide the context of the usage of the key and the sub-script k will be used to distinguish keys.

In the following, we use the **fingerprint** of a public key $I_k = \text{fingerprint}(p_k)$ in order to refer to a key-pair (p_k, s_k) .

Based on this, we use I_k , resp. (p_k, s_k) , as an identity root key pair in the following. There can be multiple thereof and we do not make any statement on who the owner of such a key is.

Now, we introduce a globally unique identifier as a tuple (X, I_k) , where I_k refers to the previously introduced fingerprint of an identity root key and X is in principle some abstract identifier such that

we can verify equality. As such, $(X, I_k) = (Y, I_l)$ if $X = Y$ and $I_k = I_l$. The identifier is globally unique by definition: there cannot be a collision as we defined two identifiers to be equal by definition if they collide. As such, the identity key I_k spans a **namespace** and guarantees that the namespace is, by definition, collision-free.

The unique identifier within the project is defined as

```
/** A namespace spanned by the fingerprint of a pub-key
 *
 * This is based on the assumption that the fingerprint is unique to the public-
 * key
 */
final case class Namespace(fingerprint: Fingerprint) extends PrettyPrinting {
  def unwrap: String = fingerprint.unwrap
  def toProtoPrimitive: String = fingerprint.toProtoPrimitive
  def toLengthLimitedString: String68 = fingerprint.toLengthLimitedString
  override def pretty: Pretty[Namespace] = prettyOfParam(_.fingerprint)
}

/** a unique identifier within a namespace
 * Based on the Ledger API PartyIds/LedgerStrings being limited to 255
 * characters, we allocate
 * - 64 + 4 characters to the namespace/fingerprint (essentially SHA256 with
 * extra bytes),
 * - 2 characters as delimiters, and
 * - the last 185 characters for the Identifier.
 */
final case class UniqueIdentifier(id: Identifier, namespace: Namespace) extends
  PrettyPrinting {
```

We use the global unique identifier to identify participant nodes $N = (N, I_k)$, parties $P = (P, I_k)$ and sync domain entities $D = (D, I_k)$ (which means that X is short for (X, I_k)). For parties P and participant nodes N , we should use a sufficiently long random number for privacy reasons. For sync domains D , we use readable names.

Incremental Changes

The topology state is built from incremental changes, so-called topology transactions $\{+/-; \omega\}_t^{[s_k]}$ where $+$ is the addition and $-$ the subsequent removal. The incremental changes are not commutative and are ordered by time. For a given operand ω we note that the only accepted sequences are $+$ or $+/-$, but that $-+$ or $--$ or $++$ are not accepted. The t denotes the time when the change was effected, i.e. when it was sequenced by the identity providing service.

The $\{.\}^{[s_k]}$ denotes the list of keys that authorized the change by signing the topology transaction. The authorization rules (which keys $[s_k]$ need to sign a topology transaction $\{.\}$) depend on the command ω . Most but not all transactions require the signatures to be nested in some form. Generally, anything that is distributed by the identity providing service needs to be signed with its key s_D and therefore $\forall \{.\}^{[s_k]} : s_D = \text{tail}[s_k]$.

For the sake of brevity, we omit the identity providing service signature using s_D in the following and assume that it is always added upon distribution together with the timestamp t .

Topology Transactions

We can distinguish three types of topology transactions: identity delegations, mapping updates, and sync domain governance updates. In the following, we establish what these transactions mean, what they do, and what the authorization rules are.

Delegation

The general delegation transaction is represented as

$$\{+/-; (?; I_k) \Rightarrow p_l\}^{s_k}$$

where the $?$ is a placeholder for a specific permissioning level. The delegation transaction indicates that a certain set of operations on the namespace spanned by the root key pair I_k is delegated to the public key p_l . The delegation is not exclusive, which means that there can be multiple keys that have to right to sign a specific transaction on the specific namespace.

There are two types of delegations:

namespace delegations: $\{+/-; (*; I_k) \Rightarrow p_l\}^{[s_k]}$ which delegates to p_l the right to do all topology transactions on that particular namespace. The signature of such a delegated key is then considered to be equivalent to the signature of the root key: $s_l \simeq s_k$. If such a namespace delegation is a *root delegation*, then the delegated key is as powerful as the root key. If the *root delegation* flag is set to false, then the key can do everything on that namespace, except issuing *NamespaceDelegation*. Therefore, such a delegation with the root delegation flag set to false effectively represents an intermediate CA, whereas with true, it's an equivalent root key. This operation is particularly useful to support offline storage of root keys, but as we will see later, it is also used to roll keys.

```
final case class NamespaceDelegation(
  namespace: Namespace,
  target: SigningPublicKey,
  isRootDelegation: Boolean,
) extends TopologyStateUpdateMapping {
```

identifier delegations: $\{+/-; (X; I_k) \Rightarrow p_l\}^{[s_k]}$ which delegates the right to assign mappings to a particular identifier (X, I_k) . With this right, the key holder can assign a party to a participant or run the party as a participant by assigning a key to it. This effectively represents a certificate.

```
final case class IdentifierDelegation(identifier: UniqueIdentifier, target:
  SigningPublicKey)
  extends TopologyStateUpdateMapping {
```

From an authorization rule perspective, these delegations can delegate permissions to other keys and can be used to verify whether a certain key is allowed to sign a topology transaction. Therefore, we use for now the notation \tilde{s}_k^I to indicate that some operation requires a signature of the root key s_k^I or by a key which was directly or indirectly authorized by the root key.

Mapping Updates

The generic second type of topology transactions are mapping updates which are represented as

$$\{+/-, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_k, \tilde{s}_l]}$$

The above transaction maps one item of one namespace to something of a second namespace. For some mapping updates, the second namespace is always equal to the first namespace and we only require a single signature. The *ct* provides context to the mapping update and might include usage restrictions, depending on the type of mapping.

For transactions that require two signatures, we support the composition of the add operation through

$$\{+, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_k, \tilde{s}_l]} = \{+, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_k]} + \{+, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_l]}$$

and the removal operation through

$$\{-, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_k, \tilde{s}_l]} = \{-, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_k]} || \{-, (X, I_k) \rightarrow (Y, I_l, ct)\}^{[\tilde{s}_l]}$$

There are four different sub-types of valid mapping transactions:

Sync Domain Keys: The mapping transaction of $\{+, D \rightarrow (p_D, ct)\}^{s_D}$ updates the keys for the sync domain entities. Valid qualifiers for *ct* are *identity*, *sequencer*, *mediator*. As every state update needs to be signed by the sync domain, the sync domain definition corresponds to the initial seed of the identity transaction stream $\{D \rightarrow (p_D, \text{identity})\}^{s_D}$. If a participant knows the sync domain ID of *D*, it can verify that this initial seed is correctly authorized by the owner of the key governing the unique identifier of the sync domain ID.

Owner to Key Mappings: The mapping transaction $\{+, (N, I_k) \rightarrow (p_l, ct)\}^{[\tilde{s}_k]}$ updates the keys that are associated with an owner such as a participant or a sync domain entity. The key purposes can be *signing* and/or *encryption*. If more than one key is defined, all systems are supposed to use the key that was observed first and is still active.

```
final case class OwnerToKeyMapping(owner: KeyOwner, key: PublicKey)
  extends TopologyStateUpdateMapping {
```

Party to Participant Mappings: The mapping transaction $\{+, (P, I_k) \rightarrow (N, I_l, ct)\}^{[\tilde{s}_k, \tilde{s}_l]}$ maps a party to a participant. The context *ct* would call out the permissions such as *submission*, *confirmation* or *observation*.

```
final case class PartyToParticipant(
  side: RequestSide,
  party: PartyId,
  participant: ParticipantId,
  permission: ParticipantPermission,
) extends TopologyStateUpdateMapping {
```

Participant State Updates

The fourth type of topology transactions are participant state updates as sync domain governance transactions $\{d|a|c|p, N\}^{s_D}$. Here, d means *disabled* (participant cannot be involved in any transaction), a means the participant is *active*, c means the participant cannot submit transactions but only *confirm*, p means the participant is *purged* and will never be back again. Participant states are owned by the operator of the committer. It is at the committer's discretion to decide whether a participant is allowed to use the sync domain or not.

```
final case class ParticipantState(
  side: RequestSide,
  domain: DomainId,
  participant: ParticipantId,
  permission: ParticipantPermission,
  trustLevel: TrustLevel,
) extends TopologyStateUpdateMapping {

  require(
    permission.canConfirm || trustLevel == TrustLevel.Ordinary,
    "participant trust level must either be ordinary or permission must be
    ←confirming",
  )
}
```

Some Considerations

Removal Authorizations

We note that the authorization rules for the addition are more strict than for the removal: Any removal can be authorized by the sync domain key s_D such that the sync domain operator can prune the topology state if necessary, which is fine, as the accessibility of a sync domain is anyway dependent on the cooperation of the sync domain operator.

Therefore, when talking about removal authorization, we explain the authorization check the IPS will make if it receives a removal request from an untrusted source. Consequently, all participants will at least be aware whether a certain topology transaction removal was authorized by the sync domain topology manager or by the actual authority of that topology transaction.

Revocations

One important point to note is that all topology transactions have a local effect. This means that the removal of a root key $\{-, p_k\}$ does not invalidate all transactions that have been signed previously by the key, directly or indirectly. To revoke a key as in invalidating everything the key has signed requires publishing a set of topology transactions together.

Synchronization Domain Topology State

Looking at the given formalism, we can distinguish between the *topology state* and the *sync domain topology state*. The difference between these two is that the *topology state* is comprised of all delegation and mapping transactions. The *sync domain topology state* extends this definition by adding *sync domain governance updates* such as participant states. The *sync domain topology state* overrides the authorization rule by allowing a sync domain to remove any previous topology transaction.

Bootstrapping

Based on the above explanations, we observe that the authorized sync domain topology state is given by all signed and properly authorized topology transactions which additionally have been ordered and signed by the sync domain topology manager and distributed (and signed) by the sequencer. Consequently, for a new participant connecting to a sync domain, to validate the topology state and know that they are talking to the right sequencer, it only needs to know the unique identifier of the sync domain. Using this unique identifier, the participant can verify the authenticity and correctness of the topology state, as it can verify the correct authorization of the corresponding topology transactions.

This is the bootstrapping problem of any Canton network: To connect to a sync domain, a participant needs to know the sync domain ID (a unique identifier) of a sync domain, which it needs to receive through a trusted channel.

Default Party

Given that (N, I_k) and (P, I_k) are both unique identifiers used to refer to participants and parties, we can introduce for every participant its default party. This provides a more straightforward meaning of a party as being a virtualization concept on top of the synchronization structure.

Therefore, any party in the system can either self-host on a participant, or delegate the hosting to another participant. Or do a mixture of both.

Submission vs Confirmation

Due to sub-transaction privacy, validating participants only learn the identity of the submitter if they are stakeholders of the root transaction node. A malicious participant with *confirmation* permissions for a party can submit transactions in the name of the party. This behavior can be detected by any other participant hosting the party, but these participants cannot prevent the transaction from being accepted. Therefore, the distinction between *submission* and *confirmation* permissions in the party-to-participant mappings is only guaranteed to be respected by the software provided by Digital Asset.

Topology State Accumulation

Now, we define the topology state S_t at time t as provided by the identity service provider of a sync domain incrementally as

$$\begin{aligned} S_t &= S_{t-1} + \{., \omega\}_t^{s_k, s_{k'}} \\ &= \bigoplus_{t' < t} \{., \omega\}_{t'}^{[s.]} \\ &= [(\cdot, I) \Rightarrow p] + [((X, I) \rightarrow Y)] + [(\cdot, N)] \end{aligned}$$

Here, the first expression on the last line represents the delegations, the second corresponds to the mapping updates and the third one to the participant state updates.

We assume that the identity providing service (which is part of the committer) is presented by someone with a topology transaction $\{.\}^{s_k}$. Upon a vetting operation where the operator can decide if the proposed change is acceptable, the IPS sequences, validates, signs (using the sync domain key s_D) and distributes the topology state changes to all affected sync domain entities.

Privacy by Design

A tricky question is how to provide privacy by design, allowing participants only to learn about other parties and participants on a need-to-know basis, while still ensuring that enough information is available for the participant to progress and that the information remains immutable and verifiable.

We do this by generally restricting what is shared with participants by default. Instead of broadcasting the mappings $X \rightarrow Y$ to all participants, we broadcast $T = (H(X), t_id)$ instead.

We include a service with the committer that allows us to query the data once the left side has been learned. This means that once X of $H(X)$ is known, a participant can call a service that returns the corresponding topology transactions, which in turn can be verified to be justified.

Looking at the participant to key mappings $N \rightarrow K$ we note that by only broadcasting $H(N)$ instead of N , other participants cannot transact with a participant P unless they have learned P's identity. This is a similar property as we see with phone numbers. Guessing a phone number is hard. However, once we receive a call from a phone, we know the calling number.

By restricting the data we broadcast about the party to participant mappings, we prevent two aspects. First, nobody can contact a party unless they have learned the party identifier before. This is important as otherwise, any participant on the ledger might e.g. contact all parties of another participating bank. Second, we ensure that nobody can know how many parties e.g. a participant manages. This prevents learning questions such as how many parties are represented by a certain participant (how many clients does my competitor have).

Cross-Synchronization-Domain Delegations

In our design of participants and parties, we observe that a participant is a system entity whereas a party is meant to represent some actor in the real world. In order to commoditize the ledger as a service, we need to provide a way that makes a party something fluid that can be moved around from participant. As the participant should just be a service, it might be acceptable to keep it pinned to an identity sync domain. But a party should be able to travel but still be held accountable for the obligations.

Permissioning a party on a second participant node that exists in the same sync domain is already possible in the present formalism: $\{(P, I_k) \rightarrow (N_2, I_k)\}^{s_k}$

A straight-forward extension to permission a party on a second participant in another identity namespace is: $\{(P, I_k) \rightarrow (N_2, I_l)\}^{s_k, s_l}$. Based on the additivity of such statements, we can also build such a permission from two individually signed transactions.

The party delegation transaction supports delegating the permissioning of a party to a key outside of the root key namespace: $\{(P, I_k) \Rightarrow p_l\}^{s_k}$

Multi-Synchronization-Domain Transaction

The key challenge of the identity management aspect is to design it such that we can support multi-sync domain synchronization without requiring the committers to cooperate.

First, we note that we avoid collision problems by design using globally unique identifiers derived from namespaces generated by root keys.

Second, we note that we do not need complete consistency of identities between the committers. All that is required is a sufficient overlap.

We first introduce a new mapping transaction denoting the transfer permission as $\{P \rightarrow D_T\}$ on the source sync domain D_S . The transfer permission means that for the given party, out-transfers of contracts to the target sync domain D_T are allowed. However, this does not imply that the target sync domain has corresponding permission to move the contract back. It might, but there is no guarantee.

Right now, in the transfer-out protocol, the transfer-out request check reads *The target sync domain is acceptable to all stakeholders*. By introducing $\{P \rightarrow D\}$ we are now explicit about what an acceptable sync domain is: for all stakeholder parties of the particular contract, there is an appropriate transfer permission on the current sync domain.

However, there are edge cases we need to deal with: what happens if on sync domain D_T , the party P doesn't exist? Or what happens if the participants representing P on D_S are completely different than on D_T ? This can happen either due to a misconfiguration or due to a race-condition of an inflight change.

Clearly, in such a case, the transfer must fail in a predictable manner. Therefore, we introduce two new rules

1) transfer-out on D_S will be rejected if $(P \rightarrow [N])_{D_S}^{t_1} \cap (P \rightarrow [N])_{D_T}^{t_0} = \emptyset$

2) transfer-in on D_T will be rejected if $(P \rightarrow [N])_{D_S}^{t_1} \cap (P \rightarrow [N])_{D_T}^{t_2} = \emptyset$

These rules boil down to the simple verbal requirement that at least one participant representing the affected party needs to be present on both sync domains while the transfer takes place from t_0 to t_2 .

Validation

Scenario: *How to roll participant keys?*

This corresponds to $\{+, (N, I_k) \rightarrow p_2\}^{\tilde{s}_k} \{-, (N, I_k) \rightarrow p_1\}^{\tilde{s}_k}$

Scenario: *I can setup my local committer and my local participant and subsequently connect to a remote committer.*

Either locally create an identity key and get it vetted by the committer. Or get *Identifier Delegations* by another identity key holder, load it locally into the identity store, subsequently pushing to a remote committer.

Scenario: *I can register a party on multiple participants?*

$\{+, P \rightarrow N_1\} \{+, \rightarrow N_2\}$

Scenario: *I can introduce a new cryptographic signing scheme without losing my identities or I can roll a root identity key.*

Assuming that $\{I_k^S\}$ is the original key of scheme S and we want to use scheme S' , then the following transaction should suffice: $\{J_k^{S'}\}^{I_k^S}$. Now the new key is endorsed to act on the namespace originally spanned by I_k . If furthermore I_k is revoked, then the new key becomes the root key. If the signature of the old key is not trusted then the delegation needs to be believed.

There is a corresponding RFC for X509s for that <https://tools.ietf.org/html/rfc6489>

Scenario: *I can migrate a party from one participant to another.*

$$\{+, (P, I_k) \rightarrow (N_2, I_l)\}^{I_k, I_l} \{-, P \rightarrow (N_2, I_k)\}^{I_k}$$

46.2.3.3 Implementation

Synchronization Domain ID

We assume that the sync domain ID is shared with the connecting participant through a trusted channel. This can be implemented as a secure out-of-band process or by trusting TLS server authentication when initially requesting the sync domain ID from the Sequencer Service.

Identity Providing Service API

The Identity Providing Service client API is defined as follows:

```
/** Client side API for the Identity Providing Service. This API is used to get
 * information about the layout of
 * the domains, such as party-participant relationships, used encryption and
 * signing keys,
 * package information, participant states, domain parameters, and so on.
 */
class IdentityProvidingServiceClient {

  private val domains = TrieMap.empty[DomainId, DomainTopologyClient]

  def add(domainClient: DomainTopologyClient): this.type = {
```

(continues on next page)

(continued from previous page)

```

    domains += (domainClient.domainId -> domainClient)
    this
  }

  def allDomains: Iterable[DomainTopologyClient] = domains.values

  def tryForDomain(domain: DomainId): DomainTopologyClient =
    domains.getOrElse(domain, sys.error("unknown domain " + domain.toString))

  def forDomain(domain: DomainId): Option[DomainTopologyClient] = domains.
  ↪get(domain)
}

trait TopologyClientApi[+T] { this: HasFutureSupervision =>

Based on this API, the following Sync Crypto API can be built, which allows to decouple the crypto operations used in the synchronization protocol from the crypto protocol and identity management implementation.

Synchronization Crypto API

Within Canton, the entire identity, key and signing management is abstracted and hidden from the synchronization protocol behind the `SyncCryptoApi`.

```
/** impure part of the crypto api with access to private key store and knowledge
↳ about the current entity to key assoc */
trait SyncCryptoApi {

  def pureCrypto: CryptoPureApi

  def ipsSnapshot: TopologySnapshot

  /** Signs the given hash using the private signing key. */
  def sign(hash: Hash)(implicit
    traceContext: TraceContext
  ): EitherT[Future, SyncCryptoError, Signature]

  /** Decrypts a message using the private key of the public key identified by
↳ the fingerprint
    * in the AsymmetricEncrypted object.
    */
  def decrypt[M](encryptedMessage: AsymmetricEncrypted[M]) (
    deserialize: ByteString => Either[DeserializationError, M]
  )(implicit traceContext: TraceContext): EitherT[Future, SyncCryptoError, M]

  /** Verify signature of a given owner
    *
    * Convenience method to lookup a key of a given owner, domain and timestamp
↳ and verify the result.
    */
  def verifySignature(
    hash: Hash,
    signer: KeyOwner,
    signature: Signature,
  ): EitherT[Future, SignatureCheckError, Unit]

  def verifySignatures(
    hash: Hash,
    signer: KeyOwner,
    signatures: NonEmpty[Seq[Signature]],
  ): EitherT[Future, SignatureCheckError, Unit]

  /** Verifies a list of `signatures` to be produced by active members of a
↳ `mediatorGroup`,
    * counting each member's signature only once.
    * Returns `Right` when the `mediatorGroup`'s threshold is met.
    * Can be successful even if some signatures fail the check, logs the errors
↳ in that case.
    * When the threshold is not met returns `Left` with all the signature check
↳ errors.
```

(continues on next page)

(continued from previous page)

```

*/
def verifySignatures(
  hash: Hash,

}

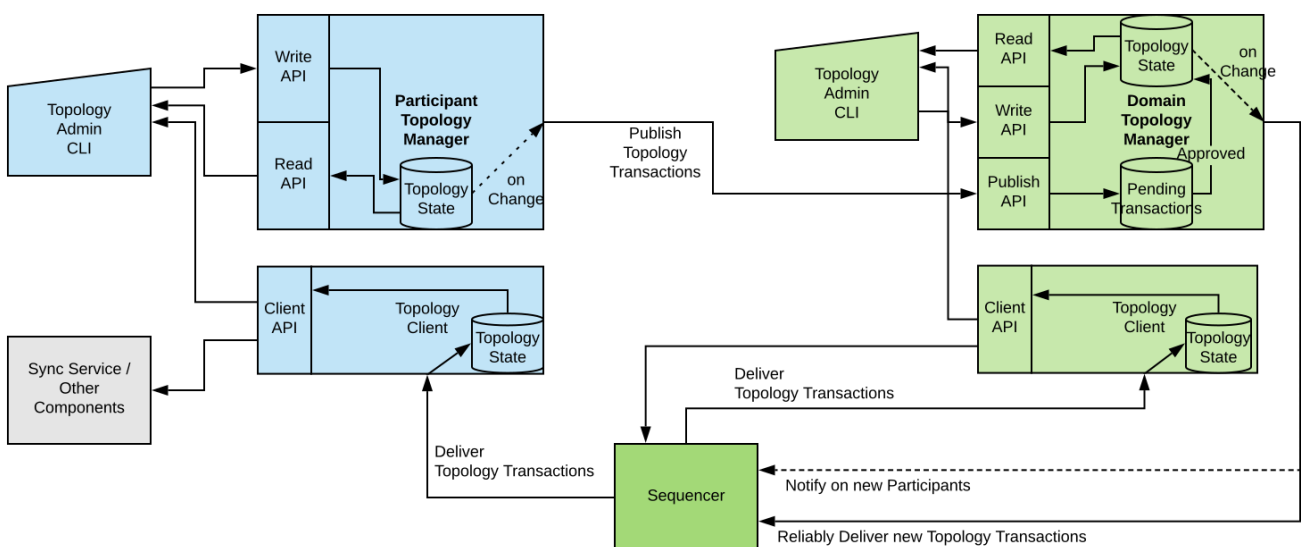

```

This class contains the appropriate methods in order to *sign*, *verify signatures*, *encrypt* or *decrypt* on a per-member basis. Which key and which cryptographic method is used is hidden entirely behind this API.

The API is obtained on a per sync domain and timestamp basis. The `SyncCryptoApiProvider` combines the information about the owner of the node, the connected sync domain, the cryptographic module in use and the topology state for a particular time and provides a factory method to obtain the `SyncCryptoApi` for a particular sync domain and time combination.

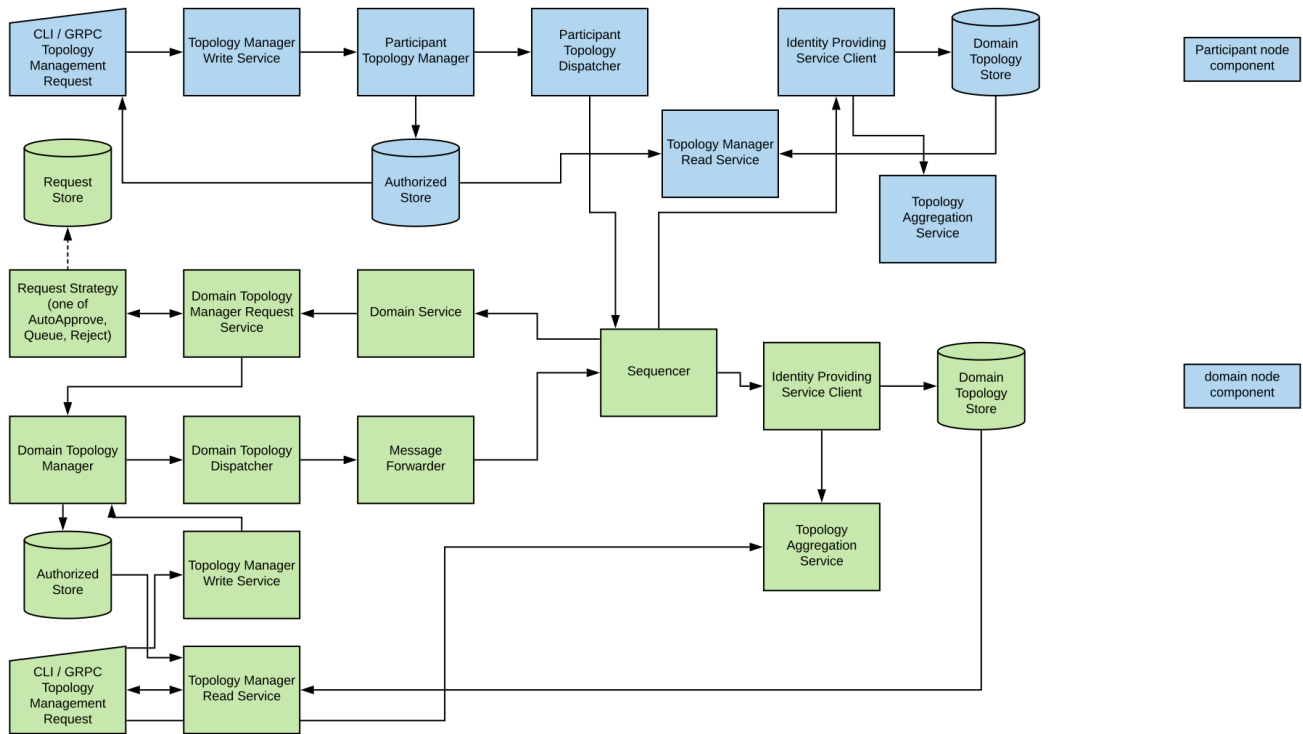

High-Level Picture

The following illustration provides a high-level overview of the identity management architecture and flows.

Transaction Flow

The following chart lays out all components of the Canton identity management system. Some of the components are shared between the participant node and sync domain, while some have slightly different functionality. The arrow indicates data flow.

In the following, we describe how a topology command invoked on the participant node propagates through the system. Ultimately, the component fully describing the topology state is the topology providing service client (TPSC). Therefore, we can track the propagation from the command until it reaches the IPSC.

CLI/GRPC Topology Management Request - The topology management system is accessible through the *topology_manager_write_service*, the *topology_manager_read_service* and the *topology_aggregation_service*, which are GRPC based services. The Canton shell exposes all these services directly through appropriate commands.

Topology Manager Write Service - In order to change the topology state, an administrator needs to create a new topology transaction and authorize it by signing it with an eligible key. These authorization commands are externally accessible using the write service, exposing the GRPC API.

Participant Topology Manager - Every participant has a local topology manager. The participant can populate the store either by importing authorized transactions or creating new authorized transactions itself. The topology manager checks every locally added transaction for consistency and correctness.

Participant Topology Dispatcher - The dispatcher monitors the topology state managed by the local topology manager and tries to push the local authorized topology state to any connected sync domain. As an example, if a party is added locally, the dispatcher tries to propagate the corresponding topology transaction to any connected sync domain.

Sequencer Connect Service - Every sequencer exposes a public service, called sequencer connect service, for handshake and administrative purposes. Here, participants obtain the applicable sync domain rules, the protocol version and the sync domain ID.

Sync Domain Topology Manager Request Service - Any topology transaction upload from the sync domain service is processed through the request service. The request service is configured with a **request strategy**. The request strategy inspects the topology transaction and decides how to deal with a topology transaction. Right now, three strategies have been implemented: auto-approve for un-permissioned sync domains, queue for permissioned sync domains (where transactions are just stored for later decision in the *Request Store*) and rejection for closed sync domains.

Sync Domain Topology Manager - Similar to the participant node topology manager, except with the added functionality required for a sync domain, allowing it to set participant states. Changes to the sync domain topology manager either come from the local administrator through the topology manager write service or through accepted topology transactions from the request service. The sequencer listens to the sync domain topology manager and sets up new member queues if a new participant is added to the system.

Sync Domain Topology Dispatcher - The sync domain topology dispatcher monitors the local authorized sync domain topology state. Upon a change, the dispatcher computes who needs to be informed of the given topology transaction (i.e. all active participant nodes). Or, if a new participant has been added, the dispatcher ensures that the first transactions a new participant will observe when connecting to the sequencer are the topology transactions. This prevents any race condition or inconsistent topology state.

Message Forwarder - The topology state requires that the topology transactions be applied in the previously established order. The message forwarder therefore ensures the absolute guaranteed in-order delivery of all topology transactions, in particular in the case of temporary delivery to sequencer failure. The message forwarder sends the topology transactions as instructed by the dispatcher via the sequencer to all participant nodes and sync domain entities.

Identity Providing Service Client - The implementation of the IPSC listens to the stream of sequenced messages and receives the identity updates. The client inspects the message, validates the signatures and appends the topology transaction to the topology state.

Topology Aggregation Service - Inspect via GRPC the aggregated topology state as exposed by the IPSC internally.

Not a direct part of the transaction flow, but essential components for topology management are the following components:

Authorized/Request/Sync Domain Topology Store - There are several stores for topology transactions. The authorized store is the set of topology transactions that have been added to the local topology manager. The sync domain topology store is the store of topology transactions that have been timestamped by the sequencer. The authorized store of a sync domain and the sync domain topology store contain the same content, except that the authorized store can hold data that has not yet been timestamped by the sequencer. The content of the sync domain topology stores on the participant (one per connected sync domain) is identical among all participants on a sync domain. These stores are used by the synchronization protocol.

Topology Manager Read Service - The topology manager read service just serves inspection purposes in order to look deeply into the topology state. The read service plugs directly into a topology store and exposes the content via GRPC.

46.2.4 Canton High-Level Requirements

As detailed in the [DA ledger model](#), the Daml ledger interoperability protocol provides parties with a *virtual shared ledger*, which contains their interaction history and the current state of their shared Daml contracts. To access the ledger, the parties must deploy (or have someone deploy for them) the so-called *participant nodes*. The participant nodes then expose the *Ledger API*, which enables the parties to request changes and get notified about the changes to the ledger. To apply the changes, the participant nodes run a synchronization protocol. We can visualize the setup as follows.

In general, the setup might be more complicated than shown above, as a single participant node can provide services for more than one party and parties can be hosted on multiple participant nodes. Note, however, that this feature is currently limited. In particular, a party hosted on multiple participants should be on-boarded on all of them before participating to any transaction.

In this section, we list the high-level functional requirements on the Ledger API, as well as non-functional requirements on the synchronization protocol.

46.2.4.1 Functional requirements

Functional requirements specify the constraints on and between the system's observable outputs and inputs. A difficulty in specifying the requirements for the synchronization service is that the system and its inputs and outputs are distributed, and that the system can include **Byzantine** participant nodes, i.e., participants that are malicious, malfunctioning or compromised. The system does not have to give any guarantees to parties using such nodes, beyond the ability to recover from malfunction/compromise. However, the system must protect the **honestly represented parties** (i.e., parties all of whose participant nodes implement the synchronization service correctly) from malicious behavior. To account for this in our requirements, we exploit the fact that the conceptual purpose of the ledger synchronization service is to provide parties with a virtual shared ledger and we:

1. use such a shared ledger and the associated properties (described in the [DA ledger model](#)) to constrain the input-output relation;
2. express all requirements from the perspective of an honestly represented party;
3. use the same shared ledger for all parties and requirements, guaranteeing synchronization.

We express the high-level functional requirements as user stories, always from the perspective of an honestly represented party, i.e., Ledger API user, and thus omit the role. As the observable inputs and outputs, we take the Ledger API inputs and outputs. Additionally, we assume that crashes and recoveries of participant nodes are observable. The requirements ensure that the virtual shared ledger describes a world that is compatible with the honestly represented parties' perspectives, but it may deviate in any respect from what Byzantine nodes present to their parties. We call such parties **dishonestly represented parties**.

Some requirements have explicit exceptions and design limitations. Exceptions are fundamental, and cannot be improved on by further design iterations. Design limitations refer to the design of the Canton synchronization protocol and can be improved in future versions. We discuss the consequences of the most important exceptions and design limitations [later in the section](#).

Note: The fulfillment of these requirements is conditional on the system's assumptions (in particular, any trusted participants must behave correctly).

Synchronization. I want the platform to provide a virtual ledger (according to the [DA ledger model](#)) that is shared with all other parties in the system (honestly represented or not), so that I stay synchronized with my counterparties.

Change requests possible. I want to be able to submit change requests to the shared ledger.

Change request identification. I want to be able to assign an identifier to all my change requests.

Change request deduplication. I want the system to deduplicate my change requests with the same identifiers, if they are submitted within a time window configurable per participant, so that my applications can resend change requests in case of a restart without adding the changes to the ledger twice.

Bounded decision time. I want to be able to learn within some bounded time from the submission (on the order of minutes) the decision about my change request, i.e., whether it was added to the ledger or not.

Design limitation: If the participant node used for the submission crashes, the bound can be exceeded. In this case the application should fail over to another participant replica.

Consensus. I want that all honestly represented counterparties come to the same conclusion of either accepting or rejecting a transaction according to the [DA ledger model](#).

Transparency. I want to get notified in a timely fashion (on the order of seconds) about the changes to my [projection of the shared ledger](#), according to the DA ledger model, so that I stay synchronized with my counterparties.

Design limitation: If the participant has crashed, is overloaded, or in case of network failures, the bound can be exceeded. In the case of a crash the application should fail over to another participant replica.

Design limitation: If the submitter node is malicious it can encrypt the transaction payload with the wrong key that my participant cannot decrypt it. I will be notified about a transaction but able to see its contents.

Integrity: ledger validity. I want the shared ledger to be [valid according to the DA ledger model](#).

Exception: The [consistency](#) aspect of the validity requirement on the shared ledger can be violated for contracts with no honestly represented signatories, even if I am an observer on the contract.

Integrity: request authenticity. I want the shared ledger to contain a record of a change with me as one of the requesters if and only if:

1. I actually requested that exact change, i.e., I submitted the change via the command submission service, and
2. I am notified that my change request was added to the shared ledger, unless my participant node crashes forever,

so that, together with the ledger validity requirement, I can be sure that the ledger contains no records of:

1. obligations imposed on me,
2. rights taken away from me, and
3. my counterparties removing their existing obligations

without my explicit consent. In particular, I am the only requester of any such change. Note that this requirement implies that the change is done atomically, i.e. either it is added in its entirety, or not at all.

Remark: As functional requirements apply only to honestly represented parties, any dishonestly represented party can be a requester of a commit on the virtual shared ledger, even if it has never submitted a command via the command submission service. However, this is possible only if **no** requester of the commit is honestly represented.

Note: The two integrity requirements come with further limitations and trust assumptions, whenever the [trust-liveness trade-offs](#) below are used.

Non-repudiation. I want the service to provide me with irrefutable evidence of all ledger changes that I get notified about, so that I can prove to a third party (e.g., a court) that a contract of which I am a stakeholder was created or archived at a certain point in time.

This item is scheduled on the Daml roadmap.

Finality. I want the shared ledger to be append-only, so that, once I am notified about a change to the ledger, that change cannot be removed from the ledger.

Daml package uploads. I want to be able to upload a new Daml package to my participant node, so that I can start using new Daml contract templates or upgraded versions of existing ones. The authority to upload packages can be limited to particular parties (e.g., a participant administrator party), or done through a separate API.

Daml package notification. I want to be able to get notified about new packages distributed to me by other parties in the system, so that I can inspect the contents of the package, either automatically or manually.

Automated Daml package distribution. I want the system to be able to notify counterparties about my uploaded Daml packages before the first time that I submit a change request that includes a contract that both comes from this new package and has the counterparty as a stakeholder on it.

Limitation The package distribution does not happen automatically on first use of a package, because manual ([Daml package vetting](#)) would lead to a rejection of the transaction.

Daml package vetting. I want to be able to explicitly approve (manually or automatically, e.g., based on a signature by a trusted party) every new package sent to me by another party, so that the participant node does not execute any code that has not been approved. The authority to vet packages can be limited to particular parties, or done through a separate API.

Exception: I cannot approve a package without approving all of its dependencies first.

No unnecessary rejections. I want the system to add all my well-authorized and Daml-conformant change requests to the ledger, unless:

1. they are duplicated, or
2. they use Daml templates my counterparties' participants have not vetted, or
3. they conflict with other changes that are included in the shared ledger prior to or at ap-

- proximately the same time as my request, or
4. the processing capacity of my participant node or the participant nodes of my counter-parties is exhausted by other change requests submitted by myself or others roughly simultaneously,

in which case I want the decision to include the appropriate reason for rejection.

Exception 1: This requirement may be violated whenever my participant node crashes, or if there is contention in the system (multiple conflicting requests are issued in a short period of time). The rejection reason reported in the decision in the exceptional case must differ from those reported because of other causes listed in this requirement.

Exception 2: If my change request contains an exercise on a contract identifier, and I have not witnessed (e.g., through [divulgence](#)) any actions on a contract with this identifier in my [projection of the shared ledger](#) (according to the DA ledger model), then my change request may fail.

Design limitation 1: My change requests can also be rejected if a participant of some counterparty (hosting a signatory or an observer) in my change request is crashed, unless some trusted participant (e.g., one run by a market operator) is a stakeholder participant on all contracts in my change request.

Design limitation 2: My change requests can also be rejected if any of my counterparties in the change request is Byzantine, unless some trusted participant (e.g., one run by a market operator) is a stakeholder participant on all contracts in my change request.

Design limitation 3: If the underlying sequencer queue is full for a participant, then we can get an unnecessary rejection. We assume however that the queue size is so large that it can be considered to be infinite, so this unnecessary rejection doesn't happen in practice, and the situation would be resolved operationally before the queue fills up.

Design limitation 4: If the mediator of the sync domain has crashed and lost the in-flight transaction, which then times out.

Seek support for notifications. I want to be able to receive notifications (about ledger changes and about the decisions on my change requests) only from a particular known offset, so that I can synchronize my application state with the set of active contracts on the shared ledger after crashes and other events, without having to read all historical changes.

Exception: A participant can define a bound on how far in the past the seek can be requested.

Active contract snapshots. I want the system to provide me a way to obtain a recent (on the order of seconds) snapshot of the set of active contracts on the shared ledger, so that I can initialize my application state and synchronize with the set of active contracts on the ledger efficiently.

Change request processing limited to participant nodes. I want only the following (and no other) functionality related to change request processing:

1. submitting change requests
2. receiving information about change request processing and results
3. (possibly) vetting Daml packages

to be exposed on the Ledger API, so that the unavailability of my or my counterparties' applications cannot influence whether a change I previously requested through the API is included in the shared ledger, except if the request is using packages not previously vetted. Note that this inclusion may still be influenced by the availability of my counterparties' participant nodes (as specified in the limitations on the [requirement on no unnecessary rejections](#))

46.2.4.2 Resource limits

This section specifies upper bounds on the sizes of data structures. The system must be able to process data structures within the given size limits.

If a data structure exceeds a limit, the system must reject transactions containing the data structure. Note that it would be impossible to check violations of resource limits at compile time; therefore the Daml compiler will not emit an error or warning if a resource limit is violated.

Maximum transaction depth: 100

Definition: The maximum number of levels (except for the top-level) in a transaction tree.

Example: The following transaction has a depth of 2:

Purpose: This limit is to mitigate the higher cost of implementing stack-safe algorithms on transaction trees. The limit may be relaxed in future versions.

Maximum depth of a Daml value: 100

Definition: The maximum numbers of nestings in a Daml value.

Example:

The value `17` has a depth of 0.

The value `{myField: 17}` has a depth of 1.

The value `[[myField: 17]]` has a depth of 2.

The value `['observer1', 'observer2', , 'observer100']` has a depth of 1.

Purpose:

1. Applications interfacing the DA ledger likely have to process Daml values and likely are developed outside of DA. By limiting the depth of Daml values, application developers have to be less concerned about stack usage of their applications. So the limit effectively facilitates the development of applications.
2. This limit allows for a readable wire format for Daml-LF values, as it is not necessary to flatten values before transmission.

46.2.4.3 Non-functional requirements

These requirements specify the characteristics of the internal system operation. In addition to the participant nodes, the implementation of the synchronization protocol may involve a set of additional operational entities. For example, this set can include a sequencer. We call a single deployment of such a set of operational entities a **sync domain**, and refer to the entities as **sync domain entities**.

As before, the requirements are expressed as user stories, with the user always being the Ledger API user. Additionally, we list specific requirements for financial market infrastructure providers. Some requirements have explicit exceptions; we discuss the consequences of these exceptions [later in the section](#).

Privacy. I want the visibility of the ledger contents to be restricted according to the [privacy model of DA ledgers](#), so that the information about any (sub)action on the ledger is provided only to participant nodes of parties privy to this action. In particular, other participant nodes must not receive any information about the action, not even in an encrypted form.

Exception: Sync domain entities operated by trusted third parties (such as market operators) may receive encrypted versions of any of the ledger data (but not plain text).

Design limitation 1: Participant nodes of parties privy to an action (according to the ledger privacy model) may learn the following:

- How deeply the action lies within a ledger commit.
- How many sibling actions each parent action has.
- The transaction identifiers (but not the transactions' contents) that have created the contracts used by the action.

Design limitation 2: Sync domain entities operated by trusted third parties may learn the hierarchical structure and stakeholders of all actions of the ledger (but none of the contents of the contracts, such as templates used or their arguments).

Transaction stream auditability. I want the system to be able to convince a third party (e.g., an auditor) that they have been presented with my complete transaction stream within a configurable time period (on the order of years), so that they can be sure that the stream represents a complete record of my ledger projection, with no omissions or additions.

Exception: The evidence can be linear in the size of my transaction stream.

Design limitation: The evidence need not be privacy-preserving with respect to other parties with whom I share participant nodes, and the process can be manual.

This item is scheduled on the Daml roadmap.

Service Auditability. I want the synchronization protocol implementation to store all requests and responses of all participant nodes within a configurable time period (on the order of years), so that an independent third party can manually audit the correct behavior of any individual participant and ensure that all requests and responses it sent comply with the protocol.

Remarks The system operator has to make a trade-off between preserving data for auditability and deleting data for system efficiency (see [Pruning](#)).

This item is scheduled on the Daml roadmap.

GDPR Compliance. I want the system to be compliant with the General Data Protection Regulation (GDPR).

Configurable trust-liveness trade-off. I want each sync domain to allow me to choose from a predefined (by the sync domain) set of trade-offs between trust and liveness for my change requests, so that my change requests get included in the ledger even if some of the participant nodes of my counterparties are offline or Byzantine, at the expense of making additional trust assumptions: on (1) the sync domain entities (for privacy and integrity), and/or (2) participant nodes run by counterparties in my change request that are marked as `VIP` by the sync domain

(for integrity), and/or (3) participant nodes run by other counterparties in my change request (also for integrity).

Exception: If the honest and online participants do not have sufficient information about the activeness of the contracts used by my change request, the request can still be rejected.

Design limitation: The only trade-off allowed by the current design is through confirmation policies. Currently, the only fully supported policies are the full, signatory, and VIP confirmation policies. The implementation does not support the serialization of other policies. Furthermore, integrity need not hold under other policies. This corresponds to allowing only the trade-off (2) above (making additional trust assumptions on VIP participants). In this case, the VIP participants must be trusted.

Note: If a participant is trusted, then the trust assumption extends to all parties hosted by the participant. Conversely, the system does not support to trust a participant for the actions performed on behalf of one party and distrust the same participant for the actions performed on behalf of a different party.

Workflow isolation. I want the system to be built such that workflows (groups of change requests serving a particular business purpose) that are independent, i.e. do not conflict with other, do not affect each other's performance.

This item is scheduled on the roadmap.

Pruning. I want the system to provide data pruning capabilities, so that the required hot storage capacity for each participant node depends only on:

1. the size of currently active contracts whose processing the node is involved in,
2. the node's past traffic volume within a (per-participant) configurable time window

and does not otherwise grow unboundedly as the system continues operating. Cold storage requirements are allowed to keep growing continuously with system operation, for auditability purposes.

Multi-sync-domain participant nodes. I want to be able to use multiple sync domains simultaneously from the same participant node.

This item is only delivered in an experimental state and scheduled on the roadmap for GA.

Internal participant node sync domain. I want to be able to use an internal sync domain for workflows involving only local parties exclusively hosted by the participant node.

This item is scheduled on the roadmap.

Connecting to sync domain. I want to be able to connect my participant node to a new sync domain at any point in time, as long as I am accepted by the sync domain operators.

Exception If the participant has been connected to a sync domain with unique contract key mode turned on, then connecting to another sync domain is forbidden.

Workflow transfer. I want to be able to transfer the processing of any Daml contract that I am a stakeholder of or have delegation rights on, from one sync domain to another sync domain that has been vetted as appropriate by all contract stakeholders through some procedure defined by the synchronization service, so that I can use sync domains with better performance, do load balancing and disaster recovery.

Workflow composability. I want to be able to atomically execute steps (Daml actions) in different workflows across different sync domains, as long as there exists a single sync domains to which all participants in all workflows are connected.

This item is scheduled on the roadmap.

Standards compliant cryptography. I want the system to be built using configurable cryptographic primitives approved by standardization bodies such as NIST, so that I can rely on existing audits and hardware security module support for all the primitives.

Secure storage of cryptographic private keys. I want the system to store cryptographic private keys in a secure way to prevent unauthorized access to the keys.

Upgradability. I want to be able to upgrade system components, both individually and jointly,

so that I can deploy fixes and improvements to the components and the protocol without stopping the system's operation.

Design Limitation 1 When a sync domain needs to be upgraded to a new protocol version a new sync domain is deployed and the participants migrate the active contracts' synchronization to the new sync domain.

Design Limitation 2 When a replicated node needs to be upgraded, all replicas of the node need to be upgraded at the same time.

Semantic versioning. I want all interfaces, protocols and persistent data schemas to be versioned, so that version mismatches are prevented. The versioning scheme must be semantic, so that breaking changes always bump the major versions.

Remark Every change in the Canton protocol leads to a new major version of the protocol, but a Canton node can support multiple protocols without requiring a major version change.

Sync domain approved protocol versions. I want sync domains to specify the allowed set of protocol versions on the sync domain, so that old versions of the protocol can be decommissioned, and new versions can be introduced and rolled back if operational problems are discovered.

Design limitation: Initially, the sync domain can specify only a single protocol version as allowed, which can change over time.

Multiple protocol compatibility. I want new versions of system components to still support at least one previous major version of the synchronization protocol, so that entities capable of using newer versions of the protocol can still use sync domains that specify only old versions as allowed.

Testability of participant node upgrades on historical data. I want to be able to test new versions of participant nodes against historical data from a time window and compare the results to those obtained from old versions, so that I can increase my certainty that the new version does not introduce unintended differences in behavior.

This item is scheduled on the roadmap.

Seamless participant failover. I want the applications using the ledger API to seamlessly fail over to my other participant nodes, once one of my nodes crashes.

Design limitation An external load balancer is required in front of the participant node replicas to direct requests to the appropriate replica.

Seamless failover for sync domain entities. I want the implementation of all sync domain entities to include seamless failover capabilities, so that the system can continue operating uninterrupted on the failure of an instance of a sync domain entity.

Backups. I want to be able to periodically back up the system state (ledger databases) so that it can be subsequently restored if required for disaster recovery purposes.

Site-wide disaster recovery. I want the system to be built with the ability to recover from the failure of an entire data center by moving the operations to a different data center, without loss of data.

Participant corruption recovery. I want to have a procedure in place that can be followed to recover from a malfunctioning or a corrupted participant node, so that when the procedure is finished I obtain the same guarantees (in particular, integrity and transparency) as the honest participants on the part of the shared ledger created after the end of the recovery procedure.

Sync domain entity corruption recovery. I want to have a procedure in place that can be followed to recover a malfunctioning or corrupted sync domain entity, so that the system guarantees can be restored after the procedure is complete.

This item is scheduled on the roadmap.

Fundamental dispute resolution. I want to have a procedure in place that allows me to limit and resolve the damage to the ledger state in the case of a fundamental dispute on the outcome of a transaction that was added to the virtual shared ledger, so that I could reconcile the set of active contracts with my counterparties in case of any disagreement over this set. Example causes of disagreement include disagreement with the state found after recovering a compromised participant, or disagreement due to a change in the regulatory environment making some existing contracts illegal.

This item is scheduled on the roadmap.

Distributed recovery of participant data. I want to be able to reconstruct which of my contracts are currently active from the information that the participants of my counterparties store, so that I can recover my data in case of a catastrophic event. This assumes that the other participants are cooperating and have not suffered catastrophic failures themselves.

This item is scheduled on the roadmap.

Adding parties to participants. I want to be able to start using the system at any point in time, by choosing to use a new or an already existing participant node.

Identity information updates. I want the synchronization protocol to track updates of the topology state, so that the parties can switch participants, and participants can roll and/or revoke keys, while ensuring continuous system operation.

Party migration. I want to be able to switch from using one participant node to using another participant node, without losing the data about the set of active contracts on the shared ledger that I am a stakeholder of. The new participant node does not need to provide me with the ledger changes prior to migration.

This item is scheduled on the roadmap.

Parties using multiple participants. I want to be able to use the system through multiple participant nodes, so that I can do load balancing, and continue using the system even if one of my participant nodes crashes.

Design limitation The usage of multiple participants by a single party is not seamless as with [participant high availability](#), because ledger offsets are different between participant nodes unless it is a replicated participant and command deduplication state is not shared among multiple participant nodes.

Read-only participants. I want to be able to configure some participants as read-only, so that I can provide a live stream of the changes to my ledger view to an auditor, without giving them the ability to submit change requests.

Reuse of off-the-shelf solutions. I want the system to rely on industry-standard abstractions for:

1. messaging
2. persistent storage (e.g., SQL)
3. identity providers (e.g., OAuth)
4. metrics (e.g., MetricsRegistry)
5. logging (e.g., Logback)
6. monitoring (e.g., exposing `/health` endpoints)

so that I can use off-the-shelf solutions for these purposes.

Metrics on APIs. I want the system to provide metrics on the state of all API endpoints in the system, and make them available on both link endpoints.

Metrics on processing. I want the system to provide metrics for every major processing phase within the system.

Component health monitoring. I want the system to provide monitoring information for every system component, so that I am alerted when a component fails.

This item is scheduled on the roadmap.

Remote debugability. I want the system to capture sufficient information such that I can debug remotely and post-mortem any issue in environments that are not within my control (OP).

Horizontal scalability. I want the system to be able to horizontally scale all parallelizable parts of the system, by adding processing units for these parts.

This item is scheduled on the roadmap.

Large transaction support. I want the system to support large transactions such that I can guarantee atomicity of large-scale workflows.

This item is scheduled on the roadmap.

Resilience to erroneous behavior. I want the system to be resilient against erroneous behavior of users and participants such that I can entrust the system to handle my business.

This item is scheduled on the roadmap.

Resilience to faulty sync domain behavior. I want the system to be able to detect and recover from faulty behavior of sync domain components, such that occasional issues do not break the system permanently.

This item is scheduled on the roadmap.

46.2.4.4 Known limitations

In this section, we explain the current limitations of Canton that we intend to overcome in future versions.

Limitations that apply always

Missing Key features

Cross-sync-domain transactions currently require the submitter of the transaction to transfer all used contracts to a common sync domain. Cross-sync-domain transactions without first transferring to a single sync domain are not supported yet. Only the stakeholders of a contract may transfer the contract to a different sync domain. Therefore, if a transaction spans several sync domains and makes use of delegation to non-stakeholders, the submitter currently needs to coordinate with other participants to run the transaction, because the submitter by itself cannot transfer all used contracts to a single sync domain.

Reliability

H2 support: The H2 database backend is not supported for production scenarios, therefore data continuity is also not guaranteed.

Manageability

Party migration is still an experimental feature. A party can already be migrated to a fresh participant that has not yet been connected to any sync domains. Party migration is currently a manual process that needs to be executed with some care.

Security

Denial of service attacks: We have not yet implemented all countermeasures to denial of service attacks. However, the sync domain already protects against faulty participants sending too many requests and message size limits protect against malicious participants trying to send large amounts of data via a sync domain. Further rate limit on the ledger API protects against malicious/faulty applications.

Public identity information: The topology state of a sync domain (i.e., participants known to the sync domain and parties hosted by them) is known to all participants connected to the sync domain.

Limitations that apply only sometimes

Manageability

Multi-participant parties: Hosting a party on several participants is an experimental feature. If such a party is involved in a contract transfer, the transfer may result in a ledger fork, because the ledger API is not able to represent the situation that a contract is transferred out of scope of a participant. If one of the participants hosting a party is temporarily disabled, the participant may end up in an outdated state. The ledger API does not support managing parties hosted on several participants.

Disabling parties: If a party is disabled on a participant, it will remain visible on the ledger API of the participant, although it cannot be used anymore.

Pruning: The public API does not yet allow for pruning of contract transfers and rotated cryptographic keys. An offline participant can prevent the pruning of contracts by its counter-participants.

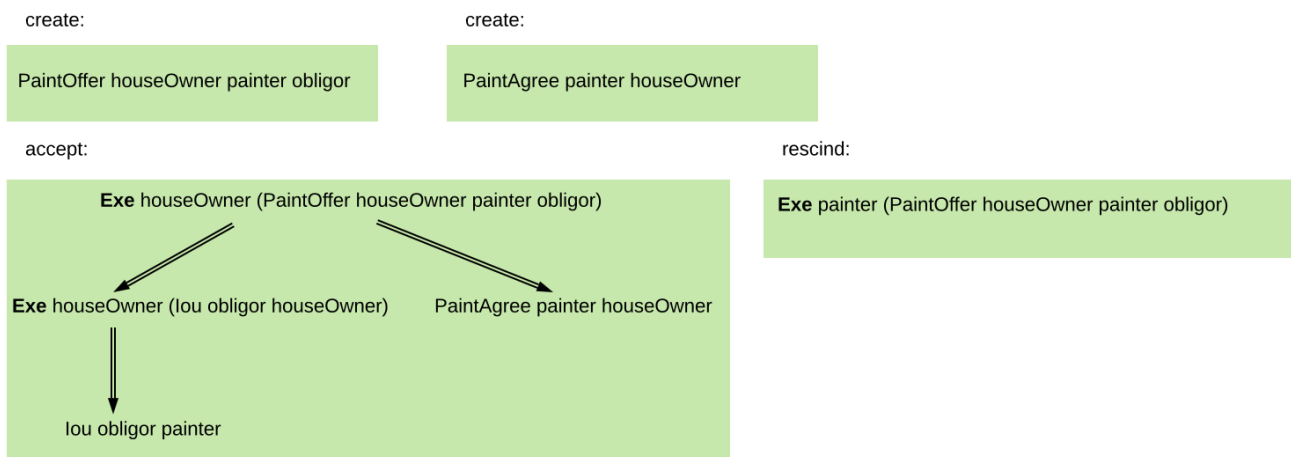

DAR and package management through the ledger API: A participant provides two APIs for managing DARs and Daml packages: the ledger API and the admin API. When a DAR is uploaded through the ledger API, only the contained packages can be retrieved through the admin API; the DAR itself cannot. When a package is uploaded through the ledger API, Canton needs to perform some asynchronous processing until the package is ready to use. The ledger API does not allow for querying whether a package is ready to use. Therefore, the admin API should be preferred for managing DARs and packages.

46.2.4.5 Requirement Exceptions: Notes

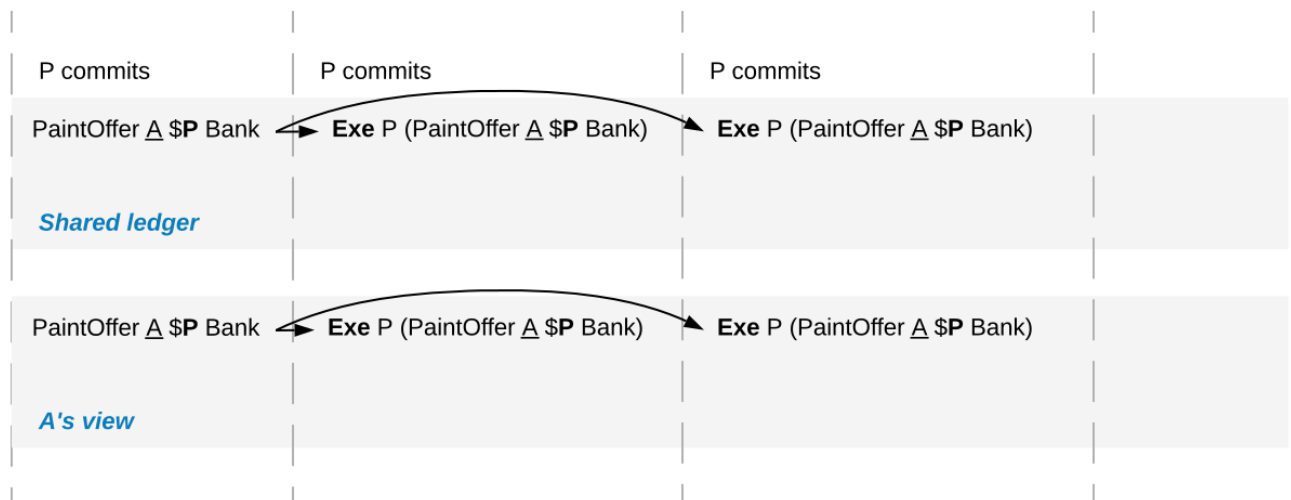

In this section, we explain the consequences of the exceptions to the requirements. In contrast to the [known limitations](#), a requirements exception is a fundamental limitation of Canton that will most likely not be overcome in the foreseeable future.

Ledger consistency

The validity requirement on the ledger made an exception for the [consistency](#) of contracts without honestly represented signatories. We explain the exception using the paint offer example from the [ledger model](#). Recall that the example assumed contracts of the form *PaintOffer houseOwner painter obligor* with the *painter* as the signatory, and the *houseOwner* as an observer (while the obligor is not a stakeholder). Additionally, assume that we extend the model with an action that allows the painter to rescind the offer. The resulting model is then:

Assume that Alice (A) is the house owner, P the painter, and that the painter is dishonestly represented, in that he employs a malicious participant, while Alice is honestly represented. Then, the following shared ledgers are allowed, together with their projections for A, which in this case are just the list of transactions in the shared ledger.

That is, the dishonestly represented painter can rescind the offer twice in the shared ledger, even though the offer is not active any more by the time it is rescinded (and thus consumed) for the second time, violating the consistency criterion. Similarly, the dishonestly represented painter can rescind an offer that was never created in the first place.

However, this exception is not a problem for the stated benefits of the integrity requirement, as the resulting ledgers still ensure that honestly represented parties cannot have obligations imposed on them or rights taken away from them, and that their counterparties cannot escape their existing obligations. For instance, the example of a malicious Alice double spending her IOU:

is still disallowed even under the exception, as long as the bank is honestly represented. If the bank was dishonestly represented, then the double spend would be possible. But the bank would not gain anything by this dishonest behavior – it would just incur more obligations.

No unnecessary rejections

This requirement made exceptions for (1) contention, and included a design limitation for (2) crashes/Byzantine behavior of participant nodes. Contention is a fundamental limitation, given the requirement for a bounded decision time. Consider a sequence cr_1, \dots, cr_n of change requests, each of which conflicts with the previous one, but otherwise have no conflicts, except for maybe cr_1 . Then all the odd-numbered requests should get added to the ledger exactly when cr_1 is added, and the even-numbered ones exactly when cr_1 is rejected. Since detecting conflicts and other forms of processing (e.g. communication, Daml interpretation) incur processing delays, deciding precisely whether cr_n gets added to the ledger takes time proportional to n . By lengthening the sequence of requests, we eventually exceed any fixed bound within which we must decide on cr_n .

Crashes and Byzantine behavior can inhibit liveness. To cope, the so-called VIP confirmation policy allows any trusted participant to add change requests to the ledger without the involvement of other parties. This policy can be used in settings where there is a central trusted party. Today's financial markets are an example of such a setting.

The no-rejection guarantees can be further improved by constructing Daml models that ensure that the submitter is a stakeholder on all contracts in a transaction. That way, rejects due to Byzantine behavior of other participants can be detected by the submitter. Furthermore, if necessary, the synchronization service itself could be changed to improve its properties in a future version, by including so-called bounded timeout extensions and attestators.

Privacy

Consider a transaction where Alice buys some shares from Bob (a delivery-versus-payment transaction). The shares are registered at the share registry SR, and Alice is paying with an IOU issued to her by a bank. We depict the transaction in the first image below. Next, we show the bank's projection of this transaction, according to the DA ledger model. Below, we demonstrate what the bank's view obtained through the ledger synchronization protocol may look like. The bank sees that the transfer happens as a direct consequence of another action that has an additional consequence. However, the bank learns nothing else about the parent action or this other consequence. It does not learn that the parent action was on a DvP contract, that the other consequence is a transfer of shares, and that this consequence has further consequences. It learns neither the number nor the identities of the parties involved in any part of the transaction other than the IOU transfer. This illustrates the first design limitation for the privacy requirement.

At the bottom, we see that the sync domain entities run by a trusted third party can learn the complete structure of the transaction and the stakeholders of all actions in the transaction (second design limitations). Lastly, they also see some data about the contracts on which the actions are performed, but this data is visible *only in an encrypted form*. The decryption keys are never shared with the sync domain entities.

46.2.5 Research Publications

Daml, Canton, and their underlying theory are described in the following research publications:

[Daml: A Smart Contract Language for Securely Automating Real-World Multi-Party Business Workflows](#) describes the theory underlying Daml’s language primitives for smart contracts and how Daml is compiled.

Alexander Bernauer, Sofia Faro, Rémy Hämmerle, Martin Huschenbett, Moritz Kiefer, Andreas Lochbihler, Jussi Mäki, Francesco Mazzoli, Simon Meier, Neil Mitchell, Ratko G. Veprek. *Daml: A Smart Contract Language for Securely Automating Real-World Multi-Party Business Workflows*. In: [arXiv:2303.03749](#), 2023.

Abstract: Distributed ledger technologies, also known as blockchains for enterprises, promise to significantly reduce the high cost of automating multi-party business workflows. We argue that a programming language for writing such on-ledger logic should satisfy three desiderata:

1. Provide concepts to capture the legal rules that govern real-world business workflows.
2. Include simple means for specifying policies for access and authorization.
3. Support the composition of simple workflows into complex ones, even when the simple workflows have already been deployed.

We present the open-source smart contract language Daml based on Haskell with strict evaluation. Daml achieves these desiderata by offering novel primitives for representing, accessing, and modifying data on the ledger, which are mimicking the primitives of today’s legal systems. Robust access and authorization policies are specified as part of these primitives, and Daml’s built-in authorization rules enable delegation, which is key for workflow composability. These properties make Daml well-suited for orchestrating business workflows across multiple, otherwise heterogeneous parties.

Daml contracts run (1) on centralized ledgers backed by a database, (2) on distributed deployments with Byzantine fault tolerant consensus, and (3) on top of conventional blockchains, as a second layer via an atomic commit protocol.

Abstract: Merkle trees are ubiquitous in blockchains and other distributed ledger technologies (DLTs). They guarantee that the involved systems are referring to the same binary tree, even if each of them knows only the cryptographic hash of the root. Inclusion proofs allow knowledgeable systems to share subtrees with other systems and the latter can verify the subtrees’ authenticity. Often, blockchains and DLTs use data structures more complicated than binary trees; authenticated data structures generalize Merkle trees to such structures.

We show how to formally define and reason about authenticated data structures, their inclusion proofs, and operations thereon as datatypes in Isabelle/HOL. The construction lives in the symbolic model, i.e., we assume that no hash collisions occur. Our approach is modular and allows us to construct complicated trees from reusable building blocks, which we call Merkle

functors. Merkle functors include sums, products, and function spaces and are closed under composition and least fixpoints. As a practical application, we model the hierarchical transactions of Canton, a practical interoperability protocol for distributed ledgers, as authenticated data structures. This is a first step towards formalizing the Canton protocol and verifying its integrity and security guarantees.

[A semantic domain for privacy-aware smart contracts and interoperable sharded ledgers](#)

Lightning talk presented at [Certified Proofs and Programs 2021](#).

Abstract:

Daml is a Haskell-based smart contract programming language used to coordinate business workflows across trust boundaries. Daml's semantics are defined over an abstract ledger, which provides a clear semantics for Daml's authorization rules, double-spending protection, and privacy guarantees. In its simplest form, a ledger is represented as a list of commits, i.e., hierarchical transactions and their authorizers. This representation allows for easy reasoning about Daml smart contracts because the total order hides the intricacies of a distributed, Byzantine-fault tolerant system. It is also adequate for Daml running on a single blockchain, as it defines a total order on all transactions.

Yet, for distributed ledgers to fully eliminate data silos, smart contracts must not be tied to a single blockchain, which would then just become another silo. Daml therefore runs on different blockchains such as Hyperledger Fabric, Ethereum, and FISCO-BCOS as well as off-the-shelf databases. The underlying protocol Canton supports atomic transactions across all these Daml ledgers. This makes Daml ledgers sharded for higher throughput as well as interoperable to avoid data silos.

Semantically, Canton creates a virtual shared ledger by merging the individual ledgers' lists of commits. The virtual shared ledger is not totally ordered, to account for the fact that there is no global notion of time across ledgers. Still, transactions can use only contracts that have been created within earlier transactions. This ensures that causality is respected even though individual system users cannot see all dependencies due to the privacy rules. Canton tracks privacy-aware causality using vector clocks.

To ensure that Daml and Canton achieve their claimed properties, we have started to formalize the Daml ledger model and prove its properties in Isabelle/HOL. The two main verification goals are as follows:

1. Canton's vector clock tracking correctly implements causality.
2. The synchronization due to vector clocks cannot cause deadlocks.

The challenge here is that these guarantees should hold for honest nodes in the system even if other systems fail or behave Byzantine.

In the lightning talk, we give an idea of the ledger model, privacy-aware causality, and the current state of the verification.

46.2.6 Security Architecture

46.2.6.1 Secure Cryptographic Private Key Storage

In this section we describe Canton's two different approaches to securing the storage of cryptographic private keys. When enabled, we leverage a Key Management Service (KMS) to either: (a) *host an encryption key that is used to transparently encrypt the private keys (i.e. envelope encryption) before storing them in Canton's database*; or (b) *directly use a KMS to perform cryptographic operations without access to the private keys*. While using envelope encryption we make sure that an attacker who has access to the database (e.g., a malicious database operator) cannot get access to the private keys from a Canton node, which would compromise the transaction privacy and integrity guarantees of Canton. If we instead decide to externalize private key storage, we go one step further and protect against an

attacker with privileged access to the node's system that can inspect the memory.

Background

Canton uses cryptography in several ways to provide a secure, minimal trust platform. In Canton we distinguish between three types of keys: short-term, long-term, and permanent keys.

Short-term key: These are used to encrypt transaction payloads. The secrets for these keys are already transmitted and stored in an encrypted form, and used only once.

Long-term key: These are keys that are used for topology transaction signing, transaction protocol signing, and encryption of short-term key secrets.

Permanent key: A [namespace root signing key](#) is a permanent key. It cannot be rotated without losing the namespace, as the namespace is identified by the fingerprint of the signing key. This is an architectural feature.

Long-term and permanent keys are by default stored in clear. Canton can, [if enabled](#), offer confidentiality at rest for these private keys. Short-term keys do not require additional protection because they are derived from a secret that is already transmitted and stored in an encrypted form using a long-term public encryption key.

Long-term keys should be governed by an operational security policy with a requirement to rotate these keys periodically or if one of them is compromised.

Requirements

The long-term keys must not be available on disk or in storage in a way that would allow someone with access to the storage to view/access the key.

The keys must not be part of Canton's container images.

A key administrator can rotate both the KMS key and the long-term keys in Canton.

Historical contract data can be decrypted using old long-term, encrypted keys that have been superseded. No old long-term keys are used in future transactions.

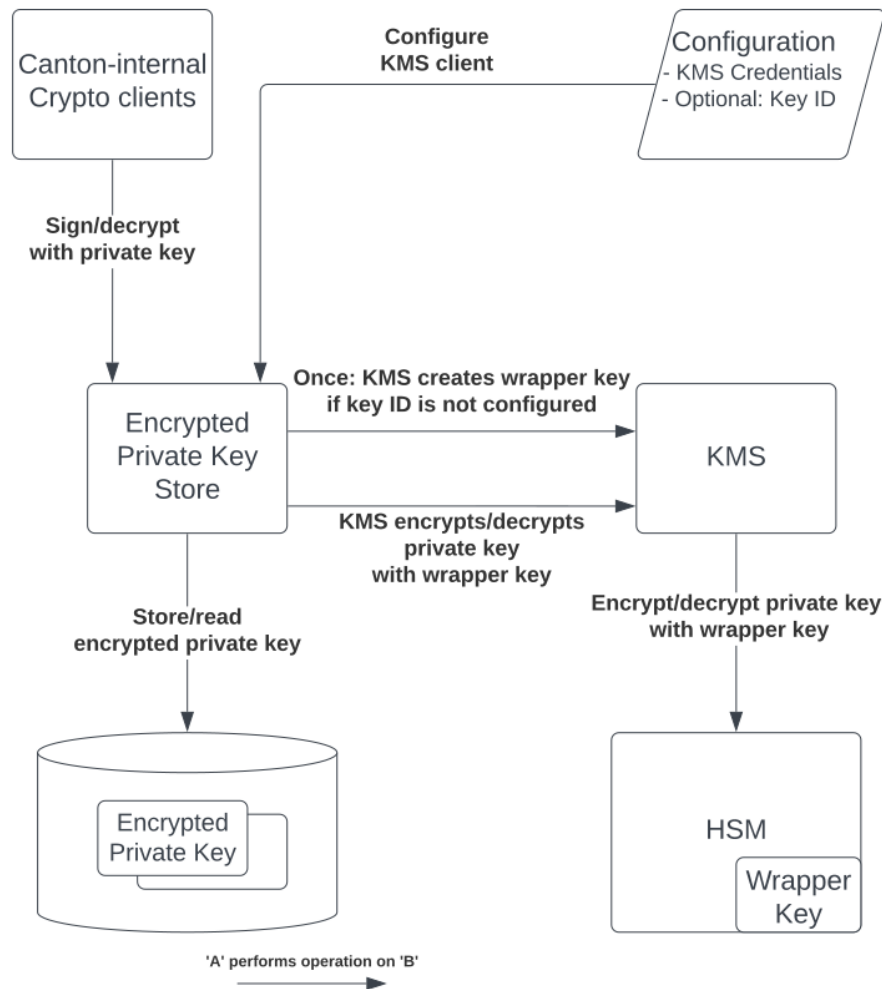

Backup and subsequent restoration of the database of a participant node supports KMS key rotation and rotation of Canton's long-term keys.

For high availability operation, Canton supports duplication of keys.

Note: Confidentiality at runtime for the private keys is out of scope. If envelope encryption is used then we do not protect against an attacker that has privileged access to the node's system and can inspect the memory.

Protect Private Keys With Envelope Encryption and a Key Management Service

Canton can protect private keys by forcing them to be internally stored in an encrypted form so they can't be decrypted and used to create fraudulent transactions. This protection at rest safeguards against malicious adversaries that get access to a node's storage layer. Keys will only be decrypted when being used and stored in a memory cache for fast access. We currently make use of a KMS's ability to securely perform this encryption/decryption of keys using a symmetric encryption key, which we call *KMS wrapper key*, without ever exposing it to the outside world, as it is backed by Hardware Security Modules (HSM) that move the crypto operations to a secure enclave.

Directly encrypting the Canton private keys with a KMS wrapper key, i.e. *envelope encryption*, has multiple advantages compared to storing these keys in the KMS itself:

- Reduces the impact on performance due to additional latency and the probability of [throttling KMS API](#) requests if the thresholds are exceeded.

- Preserves Canton's current key schemes, which remain flexible and easily modifiable. Not all KMS implementations offer modern and fast signing schemes such as Ed25519.

The confidentiality of the Canton private long-term and permanent keys depends on the access to the KMS wrapper key. The KMS must be locked down appropriately:

- Export of the symmetric key must be forbidden.

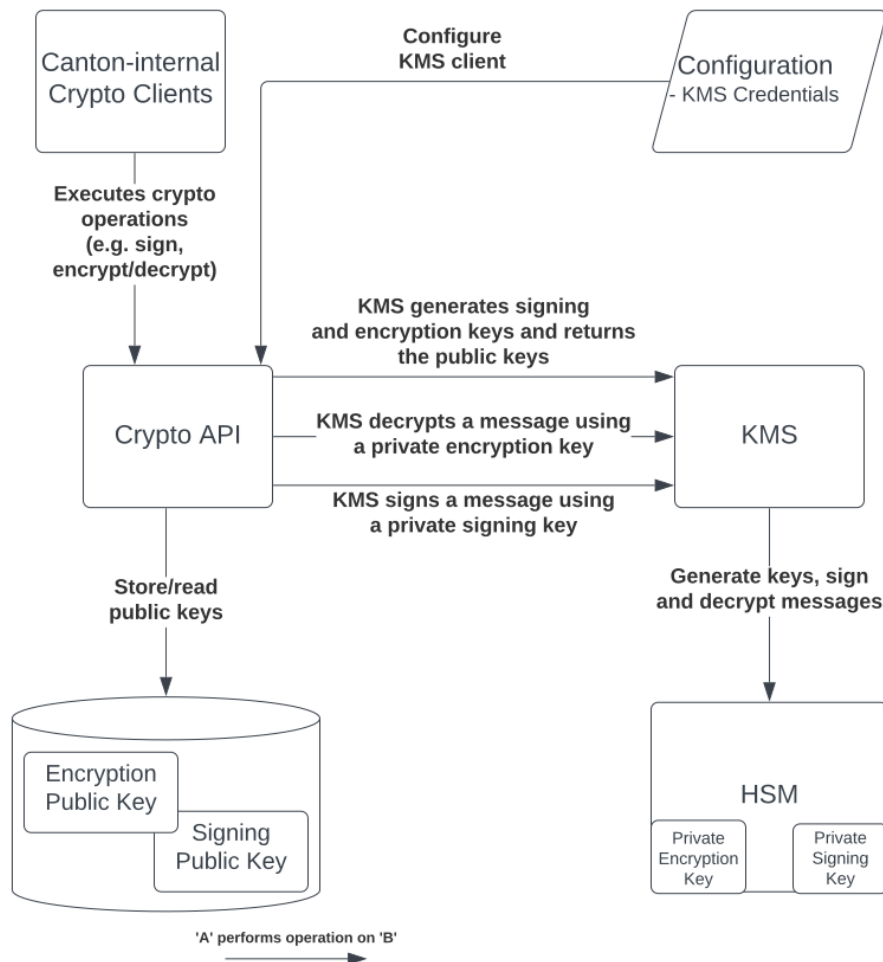

- Only authorized Canton nodes can use the wrapper key for decryption.

- Usage of the wrapper key must be logged for auditability.

- Separation of duties between the KMS operator and the database operator.

Externalize Private Keys With a Key Management Service

Canton can also protect private keys by outsourcing their generation and storage to a KMS, making use of its API to perform necessary crypto operations such as decryption and signing. This protection safeguards against malicious adversaries that, besides access to the storage layer, can also access the node's system and inspect its memory. Using a KMS's underlying monitoring framework (e.g. AWS CloudTrail Logs or GCP Cloud Audit Logs) in combination with Canton logging also offers a reliable way to maintain the security, reliability of Canton, and identify any possible misuse of its private keys.

This improvement in security comes with drawbacks, in particular:

- Added latency resulting from the need to use a KMS to decrypt and sign messages.
- Canton's supported schemes must match those provided by the KMS.

KMS Integration

Canton currently makes use of AWS or GCP KMSs to protect its private keys. The [AWS KMS API](#) or the [GCP KMS API](#) are similar to a hardware security module (HSM) where cryptographic operations can be done within the KMS using the stored keys, without exposing them outside of the KMS.

Besides offering a secure platform to create, manage, and control cryptographic keys, they also support:

- Enforcement of key usage/authorization policies;
- Access to the key usage authorization logs;
- Multi-region keys that allow for the replication of keys in multiple regions for disaster recovery;
- Automatic rotation of keys. Note that both AWS and GCP transparently select the appropriate KMS key to use, so they can be safely rotated without any code changes.

KMS Wrapper Key Rotation

[AWS](#) and [GCP](#) KMS offer two different ways to rotate keys, either automatically or manually. By default, every symmetric key created by these KMSs is set for automatic rotation (yearly for AWS, and user-defined for GCP) where only the key material is changed. The properties of the KMS key do not change and there is no need to re-encrypt the data with the newly rotated key. Management of different key versions is done seamlessly and no changes are necessary in Canton. We recommend the [rotation of the underlying Canton long-term keys](#) after the KMS key has been rotated. The rotation frequency is fixed and cannot be changed.

Fig. 15: image taken from <https://docs.aws.amazon.com/kms/latest/developerguide/rotate-keys.html>

The manual rotation of a wrapper key requires not only the creation of a new KMS key but also the re-encryption of our data with it. To do this Canton node administrators can request a manual rotation of the KMS wrapper key through the Canton console.

KMS Key Rotation

When Canton's signing and encryption keys are off-sourced to a KMS (rather than encrypted at rest with a KMS wrapper key) their rotation has to be operated manually. Neither AWS or GCP provide automatic asymmetric key rotation. Manual key rotation is achieved by requesting either: (1) a [standard rotation of Canton's keys](#), which in this case also involves the rotation of the underlying KMS key, or (2) a rotation to a previously generated KMS key `manual-kms-key-rotation`.

Satisfied Requirements

Our solutions: (a) *private key storage protection using envelope encryption* and (b) *private key externalization* comply with all the previously mentioned [requirements](#) in the following ways:

The long-term keys must not be available on disk or in storage in a way that would allow someone w

- The long-term and permanent keys are either: (a) only stored in an encrypted form in the database (the corresponding encryption key is stored securely by the KMS in an HSM), or (b) not stored at all by Canton.

The keys must not be part of Canton's container images.

- The Canton private keys are stored in the (a) database of the node or directly in the (b) external KMS and not in the container image. Credentials to access the KMS can be passed in via the environment when a container is created, the credentials must not be stored in the image.

A key administrator can both rotate the KMS key or long-term keys in Canton.

- Canton already supports manual rotation of long-term keys. In scenario (b) this also involves the re-generation of the keys in the KMS.
- Support of KMS wrapper key rotation (b) based on either: an KMS automated annual key rotation, or a manual rotation and re-encryption of the Canton private keys.

Historical contract data can be decrypted using old long-term, encrypted keys that have been super

- Canton already supports rotation of long-term keys with a synchronized state on which keys are active across nodes as part of topology management.

Backup and subsequent restoration of the database of a participant node supports KMS key rotation

- Database restoration/backup is only needed for (a) protection of keys at rest. As long as the database and the wrapper key are available, backup and restoration are unaffected by key rotation. Replicating a KMS key in multiple regions can also mitigate the impact of a failure in the primary region.
- A KMS operator must ensure its configured key store has in place a robust disaster recovery plan to prevent the permanent loss of keys.

For high availability operation, Canton supports duplication of keys.

- Canton supports AWS and GCP multi-region keys when enabled in the configuration, as well as when the operator manually creates the key and just configures the existing key id in Canton. *Note: replicating keys to other regions is a manual process by the operator and not done automatically by Canton.*

46.2.6.2 Resilience to Malicious Participants

The Canton architecture implements the Daml Ledger Model, which has the following properties to ensure ledger integrity:

Model conformance;
Signatory and controller authorization; and
Daml ledger consensus and consistency, which contributes the most to the resilience.

An overview is presented here for how the Canton run-time is resilient to a malicious participant with these properties.

The ledger API have been designed and tested to be resilient against a malicious application sending requests to a Canton participant node. The focus here is on resilience to a malicious participant.

Model Conformance

During interpretation, the Daml engine verifies that a given action for a set of Daml packages is one of the allowed actions by the party for a contract (i.e., it conforms to the model). For example in an IOU model, it is valid that the actor of a transfer action must be the same as the owner of the contract and invalid for a non-owner to attempt a transfer, because the IOU must only be transferred by the owner.

Signatory and Controller Authorization

During interpretation, the Daml engine verifies the authorization of ledger actions based on the signatories and actors specified in the model when compared with the party authorization in the submitter information of the command.

Daml Ledger Integrity

Canton architecture ensures the integrity of the ledger for honest participants despite the presence of malicious participants. The key ingredients to achieving integrity are the following:

- Deterministic transaction validation to reach consensus;
- Consistent transaction ordering and validation;
- Consistency checks with at least one honest participant per signatory party; and
- Using an authenticated data structure (generalized blinded Merkle tree) for transactions that balances consensus with privacy.

Deterministic Transaction Execution

The execution of Daml is deterministic even though there are multiple, distributed participant nodes: given a set of Daml packages that are identified by their content and a command (create or exercise), the result of a (sub-)transaction will always be the same for the involved participant nodes. This property is used by Canton to reach agreement on whether a submitted (sub-)transaction is valid or invalid – the agreement is a requirement for ledger integrity.

Consistent Transaction Ordering and Validation

Canton uses distributed conflict detection among the involved participant nodes to ensure integrity since, by design, there is no centralized component that knows the activeness of all contracts. Instead all involved participants process the transactions in the same order so that if two concurrent transactions consume the same contract only the first transaction consumes the contract and the other transaction fails (e.g., no double spend). This means that a failed consistency check does not necessarily mean the submitter was malicious; it may be the result of a race condition in the application to consume the same contract. The sequencer node guarantees that all messages are totally ordered timestamps.

The deterministic order is established with unique timestamps from the sequencer, which implements a guaranteed total order multicast; that is, the sequencer guarantees the delivery of an end-to-end encrypted message to all recipients. The deterministic order of message delivery results in a deterministic order of execution which ensures ledger integrity.

For finality and bounded decision times of transactions, the sequencer is immutable and append-only. In the event of a timeout, the timeouts of transactions are consistently derived from the sequencer timestamps so that timeouts are deterministic as well.

The set of recipients on the sequencer message can be validated by a recipient to ensure that the other participants of the transaction have been informed as well (i.e., guaranteed communication). Otherwise the malicious submitter would break consensus, resulting in a loss of ledger integrity where participants hosting a signatory are not informed about a state change.

Consistency With at Least One Honest Participant per Signatory Party

Although participants can verify model conformance and authorization on their own as described in the previous sections, the consistency check needs at least one honest participant hosting a signatory party to ensure consistency. If all signatories of a contract are hosted by dishonest participants, a transaction may use a contract even when the contract is not active.

Authenticated Data Structure for Transactions

The hierarchical transactions are represented by an authenticated data structure in the form of a generalized blinded Merkle tree (see <https://www.canton.io/publications/iw2020.pdf>). At a high level, the Merkle tree can be thought of like a blockchain in a tree format rather than a list. The Merkle tree is used to reach consensus on the hierarchical data structure while the blinding provides sub-transaction privacy. The mediator sees the shape of the transaction tree and who is involved, but no transaction payload. The entire transaction and Merkle tree is identified by its root hash. A recipient can verify the inclusion of an unblinded view by its hash in the tree. The mediator receives confirmations of a transaction for each view hash and aggregates the confirmations for the entire Merkle tree. Each participant can see all the hashes in the Merkle tree. If two participants have different hashes for the same node, the mediator will detect this and reject the transaction. The mediator also sees the number of participants involved so it can detect a missing or additional participant. The authenticated data structure ensures that participants process the same transaction and reach consensus.

Detection of Malicious Participants

In addition to the steps outlined above, the system has multiple approaches to detect malicious behavior and to keep evidence for further investigation:

- Pairs of participants periodically exchange a commitment of the active contract set (ACS) for their mutual counterparties. This ensures that any diverging views between honest participants will be detected within the ACS commitment periods and participants can repair their mutual state.

- Non-repudiation in the form of digital signatures enables honest participants to prove that they were honest and who was dishonest by preserving the signed responses of each participant.

46.2.6.3 Consensus & Transparency

[Consensus](#) and [Transparency](#) are high-level requirements that ensure that stakeholders are notified about changes to their projection of the virtual shared ledger and that they come to the same conclusions, in order to stay synchronized with their counterparties.

Operating on the Same Transaction

The Canton protocol includes the following steps to ensure that the mediator and participants can verify that they have obtained the same transaction tree given by its root hash:

- (1) Every participant gets a partially blinded Merkle tree, defining the locations of the views they are privy to.
- (2) That Merkle tree has a root. That root has a hash. That's the root hash.
- (3) The mediator receives a partially blinded Merkle tree, with the same hash.
- (4) The submitting participant will send an additional root hash message in the same batch for each receiving participant. That message will contain the same hash, with recipients being both the participant and the mediator.
- (5) The mediator will check that all participants mentioned in the tree received a root hash message and that all hashes are equal.
- (6) The mediator sends out the result message that includes the verdict and root hash.

An important aspect of this process is that transaction metadata, such as a root hash message, is not end-to-end encrypted, unlike transaction payloads which are always encrypted. The exact same message is delivered to all recipients. In the case of the root hash message, both the participant and the mediator who are recipients of the message get the exact same message delivered and can verify that both are the recipient of the message.

Stakeholders Are Notified About Their Views

Imagine the following attack scenarios on the transaction protocol at the point where a dishonest submitter prepares views.

Scenario 1: Invalid View Common Data

The submitter should send a view V2 to Alice and Bob (because it concerns them both as they are signatories), but the dishonest submitter tells the mediator that view V2 only requires the approval of Bob, and only sends it to Bob's participant. In this scenario both participants of Alice and Bob are honest.

Mitigation

The view common data is incorrect, because Alice is missing as an informee for the view V2. Given that Bob's participant is honest, he will reject the view by sending a reject to the mediator in the case of a signatory confirmation policy and not commit the invalid view to his ledger as part of phase 7. The two honest participants Alice and Bob thereby do not commit this invalid view to their ledger.

Scenario 2: Missing Sequencer Message Recipient

The dishonest submitter prepares a correct view common data with Alice and Bob as informees, but the corresponding sequencer message for the view is only addressed to Bob's participant. The confirmation policy does not require a confirmation from Alice's participant, e.g., VIP confirmation policy. In this scenario both participants of Alice and Bob are honest.

Mitigation

The mitigation relies on the following two properties of the sequencer:

(1) The trust assumption is that the sequencer is honest and actually delivers a message to all designated recipients (2) A recipient learns the identities of recipients on a particular message from a batch if it is itself a recipient of that message

The Bob participant can decrypt the view and verify the stakeholders against the set of recipients on the sequencer message. The mapping between parties and participants is part of the topology state on the sync domain and therefore the resolution is deterministic across all nodes. Seeing that the Alice participant is not a recipient despite Alice being a signatory on the view, Bob's participant will reject the view if it is a VIP participant; in any case, it will not commit the view as part of phase 7. The two honest participants Alice and Bob thereby do not commit this invalid view to their ledger.

Scenario 3: All Other Participants Dishonest

It is not required that the other participants besides Alice are honest. Let's consider a variation of the previous scenario where both the submitter and Bob are dishonest. Again Alice's participant node is not a recipient of a view message, although she is hosting a signatory. That means the view is not committed to the ledger of the honest participant Alice, because she has never seen it. Bob's participant is dishonest and approves and commits the view, although it is malformed. However, the Canton protocol does not provide any guarantees on the ledger of dishonest participants.

Scenario 4: Invalid Encryption of View

A view is encrypted with a symmetric key and the secret to derive the symmetric key for a view is encrypted with another symmetric key (i.e. a session key). This short-lived session key is encrypted for each recipient of the view with their public encryption key and the result sent to the recipients. The dishonest submitter produces a correct view and a complete recipient list of the corresponding sequencer message, but encrypts the session key for Alice with an invalid key. Alice's participant will be notified about the view but unable to decrypt it.

Mitigation

If the Alice participant is a confirmer of the invalid encrypted view, which is the default confirmation policy for signatories, then she will reject the view because it is malformed and cannot be decrypted by her.

Currently the check by the other honest participant nodes that the symmetric key secret is actually encrypted with the public keys of the other recipients is missing and a documented limitation. We need to use a deterministic encryption scheme to make the encryption verifiable, which is currently not implemented.

46.2.7 System Architecture FAQ

46.2.7.1 What does the Sequencer do?

The sequencer nodes, together with their shared sequencer backend (blockchain or database) and the schema of the sequencer backend (native smart contracts or database schema), provide message delivery between Canton nodes that is guaranteed to be order consistent, delivery consistent and multi-cast.

Multi-cast means that Alice can send a single message to multiple recipients (Carol, Dave, etc.) as one operation.

Delivery consistent means that if Alice sends a message to Carol and Dave, then either the message gets delivered to both recipients, or neither.

Order consistent means that if Alice sends a message to Carol, Dave, and others, and Bob sends a message to Carol, Dave, then Carol and Dave see the messages from Alice and Bob in the same order.

Further Reading:

[Requirements on Sequencer Domain Entity](#)
[Domain internal components](#)

46.2.7.2 How does Canton process a transaction?

Canton's execution model is that the submitting participant node computes the entire transaction using the Daml interpreter and then decomposes it into views (also known as *projections*) to other participants, and then submits those views as part of a `confirmation request` to the other involved participants and the mediator. The participants validate the received transaction views by re-computing them with the deterministic Daml interpreter, and then send confirmations to the mediator. As all the participants received the data in the same order, the outcome is deterministic, allowing to pin-point malicious behaviour. The mediator processes the confirmations and sends out an aggregated commit message to all involved participants once sufficient confirmations are received. All messages are sent via the sequencer.

Further Reading:

[Transaction processing in Canton](#)
[Daml's Execution Model](#)
[Projections](#)

46.2.7.3 How does Canton ensure privacy?

Most sequencer backend options have limited privacy features. To provide privacy even against the operator of the sequencers and sequencer backend, Canton encrypts all message payloads sent via the sequencer to be readable only by the intended recipients. That includes the transaction payloads sent as part of confirmation requests.

Canton messages are multi-cast, meaning they can have multiple recipients, and in some cases (e.g. commit requests) have different views for the different recipients. The submitter of a message generates a single-use symmetric View Encryption Key for each view, and encrypts the views using those keys. It then encrypts only a seed for that View Encryption Key using the public half of an asymmetric Participant Encryption Keys that each Canton node publishes.

The View Encryption Keys are kept - encrypted for each receiver - with the message payload itself. A receiving node uses their Participant Encryption key to decrypt the seed of the View Encryption Key for each of the views they are entitled to read, and uses a key derivation function (HKDF to be precise) to recover the View Encryption Key and read the view.

The supported encryption algorithms for asymmetric encryption (Participant Encryption Keys) and symmetric encryption (View Encryption Keys) are listed in the documentation [here](#).

46.2.7.4 Where does “the golden source” of Daml Ledger data live in Canton?

The short answer is that Daml Ledger data lives both on the Canton participant nodes and on the sequencer backend, meaning the blockchain or database enabled by the driver. The data is stored in the two places in different ways, but remains fully consistent thanks to Canton’s deterministic execution model.

All communication between Canton nodes, including the confirmation requests for transactions and the resulting confirmations and rejections, are stored on the sequencer backend. Since Daml and Canton are built around deterministic execution, you can thus consider that data on the sequencer backend, together with the Participant Encryption Keys, to be a complete copy of the Daml Ledger.

On the flip side, each Participant node stores its view of the Daml Ledger in an unencrypted format suitable for serving the Ledger API. The set of all participant nodes jointly holds the entire ledger state and history.

Further Reading:

[Transaction processing in Canton](#)

46.2.7.5 How is Canton able to recover from data loss?

As discussed in [Where does the golden source of Daml Ledger data live in Canton?](#), the ledger data lives in two places, once encrypted in the sequencer backend, and once unencrypted spread between participant nodes. As long as you have a complete copy in either place, you can recover and continue operation.

As long as the entire ledger history in the sequencer backend is available, and you hold a participant's Participant Encryption Keys, it is possible to recover the participant from the underlying sequencer backend. So if you use a blockchain as the sequencer backend, and can ensure that that blockchain stays available and uncorrupted, you can always recover from participant data loss.

Should your sequencer backend go down, but all participants are still up and running, you can continue running the system by coordinating all participant nodes to migrate active contracts to a new sync domain, with a new sequencer backend.

Should the sequencer backend no longer have the full ledger history, for example due to a sync domain switch or because of deliberate ledger pruning, participants can still recover from a combination of the partial sequencer backend and a state snapshot. Such a snapshot can come either from a backup, or from the participants' peers. At the time of writing this process is not fully automated but possible through Canton's repair endpoints.

To be able to get snapshots from peers securely, nodes regularly exchange commitments via the underlying sequencer backend. You can think of these as hashes of shared state. If Alice and Bob each run a participant, Alice's participant will regularly communicate a hash of the state it shares with Bob's participant and vice versa. As the state is the same, the hash will be the same. This provides real-time consistency checks, allows participants to detect faulty behavior in sync domain components, and also helps recovery in the above scenario. Alice can ask Bob for a snapshot of her data shared with Bob, and check its correctness by comparing it to the commitment she made on the sequencer backend.

46.3 Canton Frequently Asked Questions

This section covers other questions that frequently arise when using Canton. If your question is not answered here, consider searching the [Daml forum](#) and creating a post if you can't find the answer.

46.3.1 Log Messages

46.3.1.1 Database task queue full

If you see the log message:

```
java.util.concurrent.RejectedExecutionException:
Task slick.basic.BasicBackend$DatabaseDef$@... rejected from slick.util.
  ↳ AsyncExecutorWithMetrics$$...
[Running, pool size = 25, active threads = 25, queued tasks = 1000, completed 1
  ↳ tasks = 181375]
```

(continues on next page)

(continued from previous page)

It is likely that the database task queue is full. You can check this by inspecting the log message: if the logged `queued tasks` is equal to the limit for the database task queue, then the task queue is full. This error message does not indicate that anything is broken, and the task will be retried after a delay.

If the error occurs frequently, consider increasing the size of the task queue:

```
canton.participants.participant1.storage.config.queueSize = 10000
```

A higher queue size can lead to better performance, because it avoids the overhead of retrying tasks; on the flip side, a higher queue size comes with higher memory usage.

46.3.1.2 Serialization Exception

In some situations, you might observe the following log message in your log file or in the database log file:

```
2022-08-18 09:32:39,150 [ ] INFO c.d.c.r.DbStorageSingle - Detected an
↳SQLException. SQL state: 40001, error code: 0
    org.postgresql.util.PSQLException: ERROR: could not serialize access due to
↳concurrent update
```

This message is normally harmless and indicates that two concurrent queries tried to update a database row and due to the isolation level used, one of them failed. Currently, there are a few places where we use such queries. The Postgres manual will tell you that an application should just retry this query. This is what Canton does.

Canton's general strategy with database errors is to retry retryable errors until the query succeeds. If the retry does not succeed within a few seconds, a warning is emitted, but the query is still retried.

This means that even if you turn off the database under full load for several hours, under normal circumstances Canton will immediately recover once database access has been restored. There is no reason to be concerned functionally with respect to this message. As long as the message is logged on INFO level, everything is running fine.

However, if the message starts to appear often in your log files, you might want to check the database query latencies, number of database connections and the database load, as this might indicate an overloaded database.

46.3.2 Console Commands

46.3.2.1 I received an error saying that the DomainAlias I used was too long. Where I can see the limits of String types in Canton?

Generally speaking, you don't need to worry about too-long Strings as Canton will exit in a safe manner, and return an error message specifying the String you gave, its length and the maximum length allowed in the context the error occurred.

46.3.3 Bootstrap Scripts

46.3.3.1 Why do you have an additional new line between each line in your example scripts?

When we write `participant1 start` the scala compiler translates this into `participant1.start()`. This works great in the console when each line is parsed independently. However with a script all of its content is parsed at once, and in which case if there is anything on the line following `participant1 start` it will assume it is an argument for `start` and fail. An additional newline prevents this. Adding parenthesis would also work.

46.3.3.2 How can I use nested import statements to split my script into multiple files?

Ammonite supports splitting scripts into several files using two mechanisms. The old one is `interp.load.module(..)`. The new one is `import $file.<fname>`. The former will compile the module as a whole, which means that variables defined in one module cannot be used in another one as they are not available during compilation. The `import $file.` syntax however will make all variables accessible in the importing script. However, it only works with relative paths as e.g. `./path/to/foo/bar.sc` needs to be converted into `import $file.^.path.to.foo.bar` and it only works if the script file is named with suffix `.sc`.

46.3.3.3 How do I write data to a file and how do I read it back?

Canton uses [Protobuf](#) for serialization and as a result, you can leverage Protobuf to write objects to a file. Here is a basic example:

```
// Obtain the last event.
val lastEvent: PossiblyIgnoredProtocolEvent =
  participant1.testing.state_inspection
    .findMessage(da.name, LatestUpto(CantonTimestamp.MaxValue))
    .getOrElse(throw new NoSuchElementException("Unable to find last event."))

// Dump the last event to a file.
utils.write_to_file(lastEvent.toProtoV0, dumpFilePath)

// Read the last event back from the file.
val dumpedLastEventP: v0.PossiblyIgnoredSequencedEvent =
  utils.read_first_message_from_file[v0.PossiblyIgnoredSequencedEvent](
    dumpFilePath
  )

val dumpedLastEventOrErr: Either[
  ProtoDeserializationError,
  PossiblyIgnoredProtocolEvent,
] =
  PossiblyIgnoredSequencedEvent
    .fromProtoV0(testedProtocolVersion, cryptoPureApi(participant1.config))(
      dumpedLastEventP
    )
```

You can also dump several objects to the same file:

```
// Obtain all events.
val allEvents: Seq[PossiblyIgnoredProtocolEvent] =
  participant1.testing.state_inspection.findMessages(da.name, None, None, None)

// Dump all events to a file.
utils.write_to_file(allEvents.map(_.toProtoV0), dumpFilePath)

// Read the dumped events back from the file.
val dumpedEventsP: Seq[v0.PossiblyIgnoredSequencedEvent] =
  utils.read_all_messages_from_file[v0.PossiblyIgnoredSequencedEvent](
    dumpFilePath
  )

val dumpedEventsOrErr: Seq[Either[
  ProtoDeserializationError,
  PossiblyIgnoredProtocolEvent,
]] =
  dumpedEventsP.map {
    PossiblyIgnoredSequencedEvent.fromProtoV0(
      testedProtocolVersion,
      cryptoPureApi(participant1.config),
    )(_)
  }
}
```

Some classes do not have a (public) `toProto*` method, but they can be serialized to a [ByteString](#) instead. You can dump the corresponding instances as follows:

```
// Obtain the last acs commitment.
val lastCommitment: AcsCommitment = participant1.commitments
  .received(
    da.name,
    CantonTimestamp.MinValue.toInstant,
    CantonTimestamp.MaxValue.toInstant,
  )
  .lastOption
  .getOrElse(
    throw new NoSuchElementException("Unable to find an acs commitment.")
  )
  .message

// Dump the commitment to a file.
utils.write_to_file(
  lastCommitment.toByteString,
  dumpFilePath,
)

// Read the dumped commitment back from the file.
val dumpedLastCommitmentBytes: ByteString =
  utils.read_byte_string_from_file(dumpFilePath)

val dumpedLastCommitmentOrErr: Either[
  ProtoDeserializationError,
  AcsCommitment,
] =
  AcsCommitment.fromByteString(protocolVersion)(
    dumpedLastCommitmentBytes
  )
}
```

46.3.4 Why is Canton complaining about my database version?

46.3.4.1 Postgres

Canton is tested with the following PostgreSQL releases: 12, 13, 14, and 15. Newer PostgreSQL releases may not have been tested. The recommended version is 12. Canton WARNs when a higher version is encountered. By default, Canton does not start when the PostgreSQL version is below 10.

46.3.4.2 Oracle

Canton Enterprise additionally supports using Oracle for storage. Only Oracle 19 has been tested, so by default Canton will not start if the Oracle version is not 19.

Note that Canton's version checks use the `v$$version` table so, for the version check to succeed, this table must exist and the database user must have `SELECT` privileges on the table.

46.3.4.3 Using non-standard database versions

Canton's database version checks can be disabled with the following config option:

```
canton.parameters.non-standard-config = yes
```

Note that this will disable all `standard config` checks, not just those for the database.

46.3.5 How do I enable unsupported features?

Some alpha / beta features require you to explicitly enable them. However, please note that none of them are supported by us in our commercial product and that turning them on will very much likely break your system:

```
canton.parameters {
  # turn on non-standard configuration support
  non-standard-config = yes

  # turn on support of development version support for domain nodes
  dev-version-support = yes
}

canton.domains.mydomain.init.domain-parameters {
  # set the domain protocol version to `dev` (or to any other unstable protocol
  ↪version)
  # requires you to explicitly enable non-standard-config. not to be used for
  ↪production.
  protocol-version = dev
}

canton.participants.participant1.parameters = {
  # enable dev version on the participant (this will allow the participant to
  ↪connect to a domain with dev protocol version)
  # and it will turn on support for unsafe daml lf dev versions
  # not to be used in production and requires you to define non-standard-config =
  ↪yes
```

(continues on next page)

(continued from previous page)

```
dev-version-support = yes
}
```

46.3.6 How do I enable beta features?

For early access to new features, you need to enable beta version support. A beta protocol version allows the use of features with initial availability. Note that IA features are not generally supported. Customers using Daml Enterprise may be able to get commercial support for IA features by explicit agreement with Digital Asset. Please contact your relationship manager to discuss any such arrangement.

If you have enabled *dev version support*, you can use the beta protocol versions without any additional configuration.

```
canton.parameters {
  # turn on support of beta version support for domain nodes
  beta-version-support = yes
}

canton.domains.mydomain.init.domain-parameters {
  # set the domain protocol version to `7` (or to any other beta protocol version)
  protocol-version = 7
}

canton.participants.participant1.parameters = {
  # enable beta version on the participant (this will allow the participant to
  ↪connect to a domain with beta protocol version)
  beta-version-support = yes
}
```

46.3.7 How to troubleshoot included configuration files?

If Canton is unable to find included configuration files, please read the section on [including configuration files](#) and the [HOCON specification](#). Additionally, you may run Canton with `-Dconfig.trace=loads` to get trace information when the configuration is parsed.

Chapter 47

Test Evidence

Daml is publishing test evidence for the most important traits of tests: Security, Operability, Functional and Reliability.

It can be found in the relevant [releases](#) page, under Assets.

Chapter 48

Daml Ledger Interoperability

Certain Daml ledgers can interoperate with other Daml ledgers. That is, the contracts created on one ledger can be used and archived in transactions on other ledgers. Some Participant Nodes can connect to multiple ledgers and provide their parties unified access to those ledgers via the [Ledger API](#). For example, when an organization initially deploys two workflows to two Daml ledgers, it can later compose those workflows into a larger workflow that spans both ledgers.

Interoperability may limit the visibility a Participant Node has into a party's ledger projection, i.e., its [local ledger](#), when the party is hosted on multiple Participant Nodes. These limitations influence what parties can observe via the Ledger API of each Participant Node. In particular, interoperability affects which events a party observes and their order. This document explains the visibility limitations due to interoperability and their consequences for the Transaction Service, by [example](#) and formally by introducing interoperable versions of [causality graphs](#) and [projections](#).

The presentation assumes that you are familiar with the following concepts:

The [Ledger API](#)

The [Daml Ledger Model](#)

[Local ledgers and causality graphs](#)

Note: Interoperability for Daml ledgers is under active development. This document describes the vision for interoperability and gives an idea of how the Ledger API services may change and what guarantees are provided. The described services and guarantees may change without notice as the interoperability implementation proceeds.

48.1 Interoperability Examples

48.1.1 Topology

Participant Nodes connect to Daml ledgers and parties access projections of these ledgers via the Ledger API. The following picture shows such a setup.

The components in this diagram are the following:

There is a set of interoperable **Daml ledgers**: Ledger 1 (green) and Ledger 2 (yellow).

Each **Participant Node** is connected to a subset of the Daml ledgers.

- Participant Nodes 1 and 3 are connected to Ledger 1 and 2.

Fig. 1: Example topology with two interoperable ledgers

- Participant Node 2 is connected to Ledger 1 only.
- Participant Nodes host parties on a subset of the Daml ledgers they are connected to. A Participant Node provides a party access to the Daml ledgers that it hosts the party on.
- Participant Node 1 hosts Alice on Ledger 1 and 2.
 - Participant Node 2 hosts Alice on Ledger 1.
 - Participant Node 3 hosts the painter on Ledger 1 and 2.

48.1.2 Aggregation at the Participant

The Participant Node assembles the updates from these ledgers and outputs them via the party's Transaction Service and Active Contract Service. When a Participant Node hosts a party only on a subset of the interoperable Daml ledgers, then the transaction and active contract services of the Participant Node are derived only from those ledgers.

For example, in the [above topology](#), when a transaction creates a contract with stakeholder Alice on Ledger 2, then *P1*'s transaction stream for Alice will emit this transaction and report the contract as active, but Alice's stream at *P2* will not.

48.1.3 Enter and Leave Events

With interoperability, a transaction can use a contract whose creation was recorded on a different ledger. In the [above topology](#), e.g., one transaction creates a contract *c1* with stakeholder Alice on Ledger 1 and another archives the contract on Ledger 2. Then the Participant Node *P2* outputs the **Create** action as a `CreatedEvent`, but not the **Exercise** in form of an `ArchiveEvent` on the transaction service because Ledger 2 can not notify *P2* as *P2* does not host Alice on Ledger 2. Conversely, when one transaction creates a contract *c2* with stakeholder Alice on Ledger 2 and another archives the contract on Ledger 1, then *P2* outputs the `ArchivedEvent`, but not the `CreatedEvent`.

To keep the transaction stream consistent, *P2* additionally outputs a **Leave** *c1* action on Alice's transaction stream. This action signals that the Participant Node no longer outputs events concerning this contract; in particular not when the contract is archived. The contract is accordingly no longer reported in the active contract service and cannot be used by command submissions.

Conversely, *P2* outputs an **Enter** *c2* action some time before the `ArchivedEvent` on the transaction stream. This action signals that the Participant Node starts outputting events concerning this contract. The contract is reported in the Active Contract Service and can be used by command submission.

The actions **Enter** and **Leave** are similar to a **Create** and a consuming **Exercise** action, respectively, except that **Enter** and **Leave** may occur several times for the same contract whereas there should be at most one **Create** action and at most one consuming **Exercise** action for each contract.

These **Enter** and **Leave** events are generated by the underlying interoperability protocol. This may happen as part of command submission or for other reasons, e.g., load balancing. It is guaranteed that the **Enter** action precedes contract usage, subject to the trust assumptions of the underlying ledgers and the interoperability protocol.

A contract may enter and leave the visibility of a Participant Node several times. For example, suppose that the painter submits the following commands and their commits end up on the given ledgers.

1. Create a contract *c* with signatories Alice and the painter on Ledger 2
2. Exercise a non-consuming choice *ch1* on *c* on Ledger 1.
3. Exercise a non-consuming choice *ch2* on *c* on Ledger 2.
4. Exercise a consuming choice *ch3* on *c* on Ledger 1.

Then, the transaction tree stream that *P2* provides for *A* contains five actions involving contract *c*: **Enter**, non-consuming **Exercise**, **Leave**, **Enter**, consuming **Exercise**. Importantly, *P2* must not omit the **Leave** action and the subsequent **Enter**, even though they seem to cancel out. This is because their presence indicates that *P2*'s event stream for Alice may miss some events in between; in this example, exercising the choice *ch2*.

The flat transaction stream by *P2* omits the non-consuming exercise choices. It nevertheless contains the three actions **Enter**, **Leave**, **Enter** before the consuming **Exercise**. This is because the Participant Node cannot know at the **Leave** action that there will be another **Enter** action coming.

In contrast, *P1* need not output the **Enter** and **Leave** actions at all in this example because *P1* hosts Alice on both ledgers.

48.1.4 Cross-ledger Transactions

With interoperability, a cross-ledger transaction can be committed on several interoperable Daml ledgers simultaneously. Such a cross-ledger transaction avoids some of the synchronization overhead of **Enter** and **Leave** actions. When a cross-ledger transaction uses contracts from several Daml ledgers, stakeholders may witness actions on their contracts that are actually not visible on the Participant Node.

For example, suppose that the [split paint counteroffer workflow](#) from the causality examples is committed as follows: The actions on *CounterOffer* and *PaintAgree* contracts are committed on Ledger 1. All actions on *lou*s are committed on Ledger 2, assuming that some Participant Node hosts the Bank on Ledger 2. The last transaction is a cross-ledger transaction because the archival of the *CounterOffer* and the creation of the *PaintAgreement* commits on Ledger 1 simultaneously with the transfer of Alice's *lou* to the painter on Ledger 2.

For the last transaction, Participant Node 1 notifies Alice of the transaction tree, the two archivals and the *PaintAgree* creation via the Transaction Service as usual. Participant Node 2 also outputs the whole transaction tree on Alice's transaction tree stream, which contains the consuming **Exercise** of Alice's *lou*. However, it has not output the **Create** of Alice's *lou* because *lou* actions commit on Ledger 2, on which Participant Node 2 does not host Alice. So Alice merely witnesses the archival even though she is an *informee* of the exercise. The **Exercise** action is therefore marked as merely being witnessed on Participant Node 2's transaction tree stream.

In general, an action is marked as **merely being witnessed** when a party is an *informee* of the action, but the action is not committed on a ledger on which the Participant Node hosts the party. Unlike **Enter** and **Leave**, such witnessed actions do not affect causality from the participant's point of view and therefore provide weaker ordering guarantees. Such witnessed actions show up neither in the flat transaction stream nor in the Active Contracts Service.

For example, suppose that the **Create** *PaintAgree* action commits on Ledger 2 instead of Ledger 1, i.e., only the *CounterOffer* actions commit on Ledger 1. Then, Participant Node 2 marks the **Create** *PaintAgree* action also as merely being witnessed on the transaction tree stream. Accordingly, it does not report the contract as active nor can Alice use the contract in her submissions via Participant Node 2.

48.2 Multi-ledger Causality Graphs

This section generalizes *causality graphs* to the interoperability setting.

Every active Daml contract resides on at most one Daml ledger. Any use of a contract must be committed on the Daml ledger where it resides. Initially, when the contract is created, it takes up residence on the Daml ledger on which the **Create** action is committed. To use contracts residing on different Daml ledgers, cross-ledger transactions are committed on several Daml ledgers.

However, cross-ledger transactions incur overheads and if a contract is frequently used on a Daml ledger that is not its residence, the interoperability protocol can migrate the contract to the other Daml ledger. The process of the contract giving up residence on the origin Daml ledger and taking up residence on the target Daml ledger is called a **contract transfer**. The **Enter** and **Leave** events on the transaction stream originate from such contract transfers, as will be explained below. Moreover, contract transfers are synchronization points between the origin and target Daml ledgers and therefore affect the ordering guarantees. We therefore generalize causality graphs for interoperability.

Definition Transfer action A **transfer action** on a contract *c* is written **Transfer** *c*. The *informees* of the transfer actions are the stakeholders of *c*.

In the following, the term *action* refers to transaction actions (**Create**, **Exercise**, **Fetch**, and **NoSuchKey**) as well as transfer actions. In particular, a transfer action on a contract *c* is an action on *c*. Transfer actions do not appear in transactions though. So a transaction action cannot have a transfer action as a consequence and transfer actions do not have consequences at all.

Definition Multi-Ledger causality graph A **multi-ledger causality graph** *G* for a set *Y* of Daml ledgers is a finite, transitively closed, directed acyclic graph. The vertices are either transactions or transfer actions. Every action is possibly annotated with an **incoming ledger** and an **outgoing ledger** from *Y* according to the following table:

Action	incoming ledger	outgoing ledger
Create	no	yes
consuming Exercise	yes	no
non-consuming Exercise	yes	yes
Fetch	yes	yes
NoSuchKey	no	no
Transfer	maybe	maybe

For non-consuming **Exercise** and **Fetch** actions, the incoming ledger must be the same as the outgoing ledger. **Transfer** actions must have at least one of them. A **transfer** action with both set represents a complete transfer. If only the incoming ledger is set, it represents the partial information of an **Enter** event; if only outgoing is set, it is the partial information of a **Leave** event. **Transfer** actions with missing incoming or outgoing ledger annotations referred to as **Enter** or **Leave** actions, respectively.

The [action order](#) generalizes to multi-ledger causality graphs accordingly.

In the [example for Enter and Leave events](#) where the painter exercises three choices on contract *c* with signatories Alice and the painter, the four transactions yield the following multi-ledger causality graph. Incoming and outgoing ledgers are encoded as colors (green for Ledger 1 and yellow for Ledger 2). **Transfer** vertices are shown as circles, where the left half is colored with the incoming ledger and the right half with the outgoing ledger.

Fig. 2: Multi-Ledger causality graph with transfer actions

Note: As for ordinary causality graphs, the diagrams for multi-ledger causality graphs omit transitive edges for readability.

As an example of a cross-domain transaction, consider the [split paint counteroffer workflow with the cross-domain transaction](#). The corresponding multi-ledger causality graph is shown below. The last transaction *tx4* is a cross-ledger transaction because its actions have more than one color.

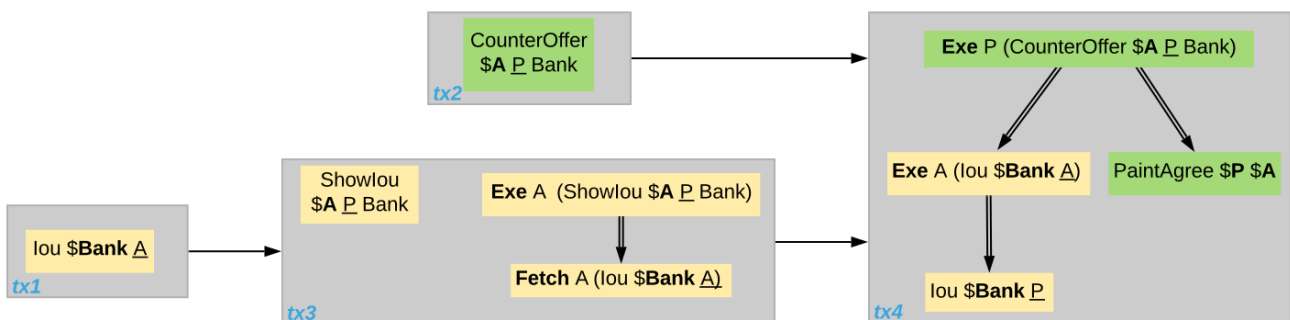

Fig. 3: Multi-Ledger causality graph for the split paint counteroffer workflow on two Daml ledgers

48.2.1 Consistency

Definition Ledger trace A **ledger trace** is a finite list of pairs (a_i, b_i) such that $b_{i-1} = a_i$ for all $i > 0$. Here a_i and b_i identify Daml ledgers or are the special value *NONE*, which is different from all Daml ledger identifiers.

Definition Multi-Ledger causal consistency for a contract Let G be a multi-ledger causality graph and X be a set of actions from G on a contract in c . The graph G is **multi-ledger consistent for the contract** c on X if all of the following hold:

1. If X is not empty, then X contains a **Create** or at least one **Enter** action. If it contains a create, then this create precedes all other actions in X . If it does not, then there exists one **Enter** action that precedes all other actions in X .
2. X contains at most one **Create** action.
3. If X contains a consuming **Exercise** action act , then act follows all other actions in X in G 's action order.
4. All **Transfer** actions in X are ordered with all other actions in X .
5. For every maximal chain in X (i.e., maximal totally ordered subset of X), the sequence of (incoming ledger, outgoing ledger) pairs is a ledger trace, using *NONE* if the action does not have an incoming or outgoing ledger annotation.

The first three conditions mimic the conditions of [causal consistency](#) for ordinary causality graphs. They ensure that **Create** actions come first and consuming **Exercise** actions last. An **Enter** action takes the role of a **Create** if there is no **Create**. The fourth condition ensures that all transfer actions are synchronization points for a contract. The last condition about ledger traces ensures that contracts reside on only one Daml ledger and all usages happen on the ledger of residence. In particular, the next contract action after a **Leave** must be an **Enter**.

For example, the above [multi-ledger causality graph with transfer actions](#) is multi-ledger consistent for c . In particular, there is only one maximal chain in the actions on c , namely

Create $c \rightarrow tf1 \rightarrow \text{ExeN } B \ c \ ch1 \rightarrow tf2 \rightarrow \text{ExeN } B \ c \ ch2 \rightarrow tf3 \rightarrow \text{ExeN } B \ c \ ch3$,

and for each edge $act_1 \rightarrow act_2$, the outgoing ledger color of act_1 is the same as the incoming ledger color of act_2 . The restriction to maximal chains ensures that no node is skipped. For example, the (non-maximal) chain

Create $c \rightarrow \text{ExeN } B \ c \ ch1 \rightarrow tf2 \rightarrow \text{ExeN } B \ c \ ch2 \rightarrow tf3 \rightarrow \text{Exe } B \ c \ ch3$

is not a ledger trace because the outgoing ledger of the **Create** action (yellow) is not the same as the incoming ledger of the non-consuming **Exercise** action for $ch1$ (green). Accordingly, the subgraph without the $tf1$ vertex is not multi-ledger consistent for c even though it is a multi-ledger causality graph.

Definition Consistency for a multi-ledger causality graph Let X be a subset of actions in a multi-ledger causality graph G . Then G is **multi-ledger consistent** for X (or **X-multi-ledger consistent**) if G is multi-ledger consistent for all contracts c on the set of actions on c in X . G is **multi-ledger consistent** if G is multi-ledger consistent on all the actions in G .

Note: There is no multi-ledger consistency requirement for contract keys yet. So interoperability does not provide consistency guarantees beyond those that come from the contracts they reference. In particular, contract keys need not be unique and **NoSuchKey** actions do not check that the contract key is unassigned.

The [multi-ledger causality graph for the split paint counteroffer workflow](#) is multi-ledger consistent. In particular all maximal chains of actions on a contract are ledger traces:

contract	maximal chains
<i>Iou Bank A</i>	Create -> Fetch -> Exercise
<i>ShowIou A P Bank</i>	Create -> Exercise
<i>Counteroffer A P Bank</i>	Create -> Exercise
<i>Iou Bank P</i>	Create
<i>PaintAgree P A</i>	Create

48.2.2 Minimality and Reduction

When edges are added to an X-multi-ledger consistent causality graph such that it remains acyclic and transitively closed, the resulting graph is again X-multi-ledger consistent. The notions [minimally consistent](#) and [reduction](#) therefore generalize from ordinary causality graphs accordingly.

Definition Minimal multi-ledger-consistent causality graph An X-multi-ledger consistent causality graph G is **X-minimal** if no strict subgraph of G (same vertices, fewer edges) is an X-multi-ledger consistent causality graph. If X is the set of all actions in G , then X is omitted.

Definition Reduction of a multi-ledger consistent causality graph For an X-multi-ledger consistent causality graph G , there exists a unique minimal X-multi-ledger consistent causality graph $\text{reduce}_X(G)$ with the same vertices and the edges being a subset of G . $\text{reduce}_X(G)$ is called the **X-reduction** of G . As before, X is omitted if it contains all actions in G .

Since multi-ledger causality graphs are acyclic, their vertices can be sorted topologically and the resulting list is again a causality graph, where every vertex has an outgoing edge to all later vertices. If the original causality graph is X-consistent, then so is the topological sort, as topological sorting merely adds edges.

48.2.3 From Multi-ledger Causality Graphs to Ledgers

Multi-Ledger causality graphs G are linked to ledgers L in the Daml Ledger Model via topological sort and reduction.

Given a multi-ledger causality graph G , drop the incoming and outgoing ledger annotations and all transfer vertices, topologically sort the transaction vertices, and extend the resulting list of transactions with the requesters to obtain a sequence of commits L .

Given a sequence of commits L , use the transactions as vertices and add an edge from tx_1 to tx_2 whenever tx_1 's commit precedes tx_2 's commit in the sequence. Then add transfer vertices and incoming and outgoing ledger annotations as needed and connect them with edges to the transaction vertices.

This link preserves consistency only to some extent. Namely, if a multi-ledger causality graph is multi-ledger consistent for a contract c , then the corresponding ledger is consistent for the contract c , too. However, a multi-ledger-consistent causality graph does not yield a consistent ledger because key consistency may be violated. Conversely, a consistent ledger does not talk about the incoming and outgoing ledger annotations and therefore cannot enforce that the annotations are consistent.

48.3 Ledger-aware Projection

A Participant Node maintains a local ledger for each party it hosts and the Transaction Service outputs a topological sort of this local ledger. When the Participant Node hosts the party on several ledgers, this local ledger is an multi-ledger causality graph. This section defines the ledger-aware projection of an multi-ledger causality graph, which yields such a local ledger.

Definition Y-labelled action An action with incoming and outgoing ledger annotations is **Y-labelled** for a set Y if its incoming or outgoing ledger annotation is an element of Y .

Definition Ledger-aware projection for transactions Let Y be a set of Daml ledgers and tx a transaction whose actions are annotated with incoming and outgoing ledgers. Let Act be the set of Y -labelled subactions of tx that the party P is an informee of. The **ledger-aware projection** of tx for P on Y (**P -projection on Y**) consists of all the maximal elements of Act (w.r.t. the subaction relation) in execution order.

Note: Every action contains all its subactions. So if act is included in the P -projection on Y of tx , then all subactions of act are also part of the projection. Such a subaction act' may not be Y -labelled itself though, i.e., belong to a different ledger. If P is an informee of act' , the Participant Node will mark act' as merely being witnessed on P 's transaction stream, as explained below.

The [cross-domain transaction in the split paint counteroffer workflow](#), for example, has the following projections for Alice and the painter on the *lou* ledger (yellow) and the painting ledger (green). Here, the projections on the green ledger include the actions of the yellow ledger because a projection includes the subactions.

Definition Projection for transfer actions Let act be a transfer action annotated with an incoming ledger and/or an outgoing ledger. The **projection** of act on a set of ledgers Y removes the annotations from act that are not in Y . If the projection removes all annotations, it is empty. The **projection** of act to a party P on Y (P -**projection** on Y) is the projection of act on Y if P is a stakeholder of the contract, and empty otherwise.

Definition Multi-Ledger consistency for a party An multi-ledger causality graph G is **consistent for a party** P on a set of ledgers Y (P -**consistent** on Y) if G is multi-ledger consistent on the set of Y -labelled actions in G of which P is a stakeholder informee.

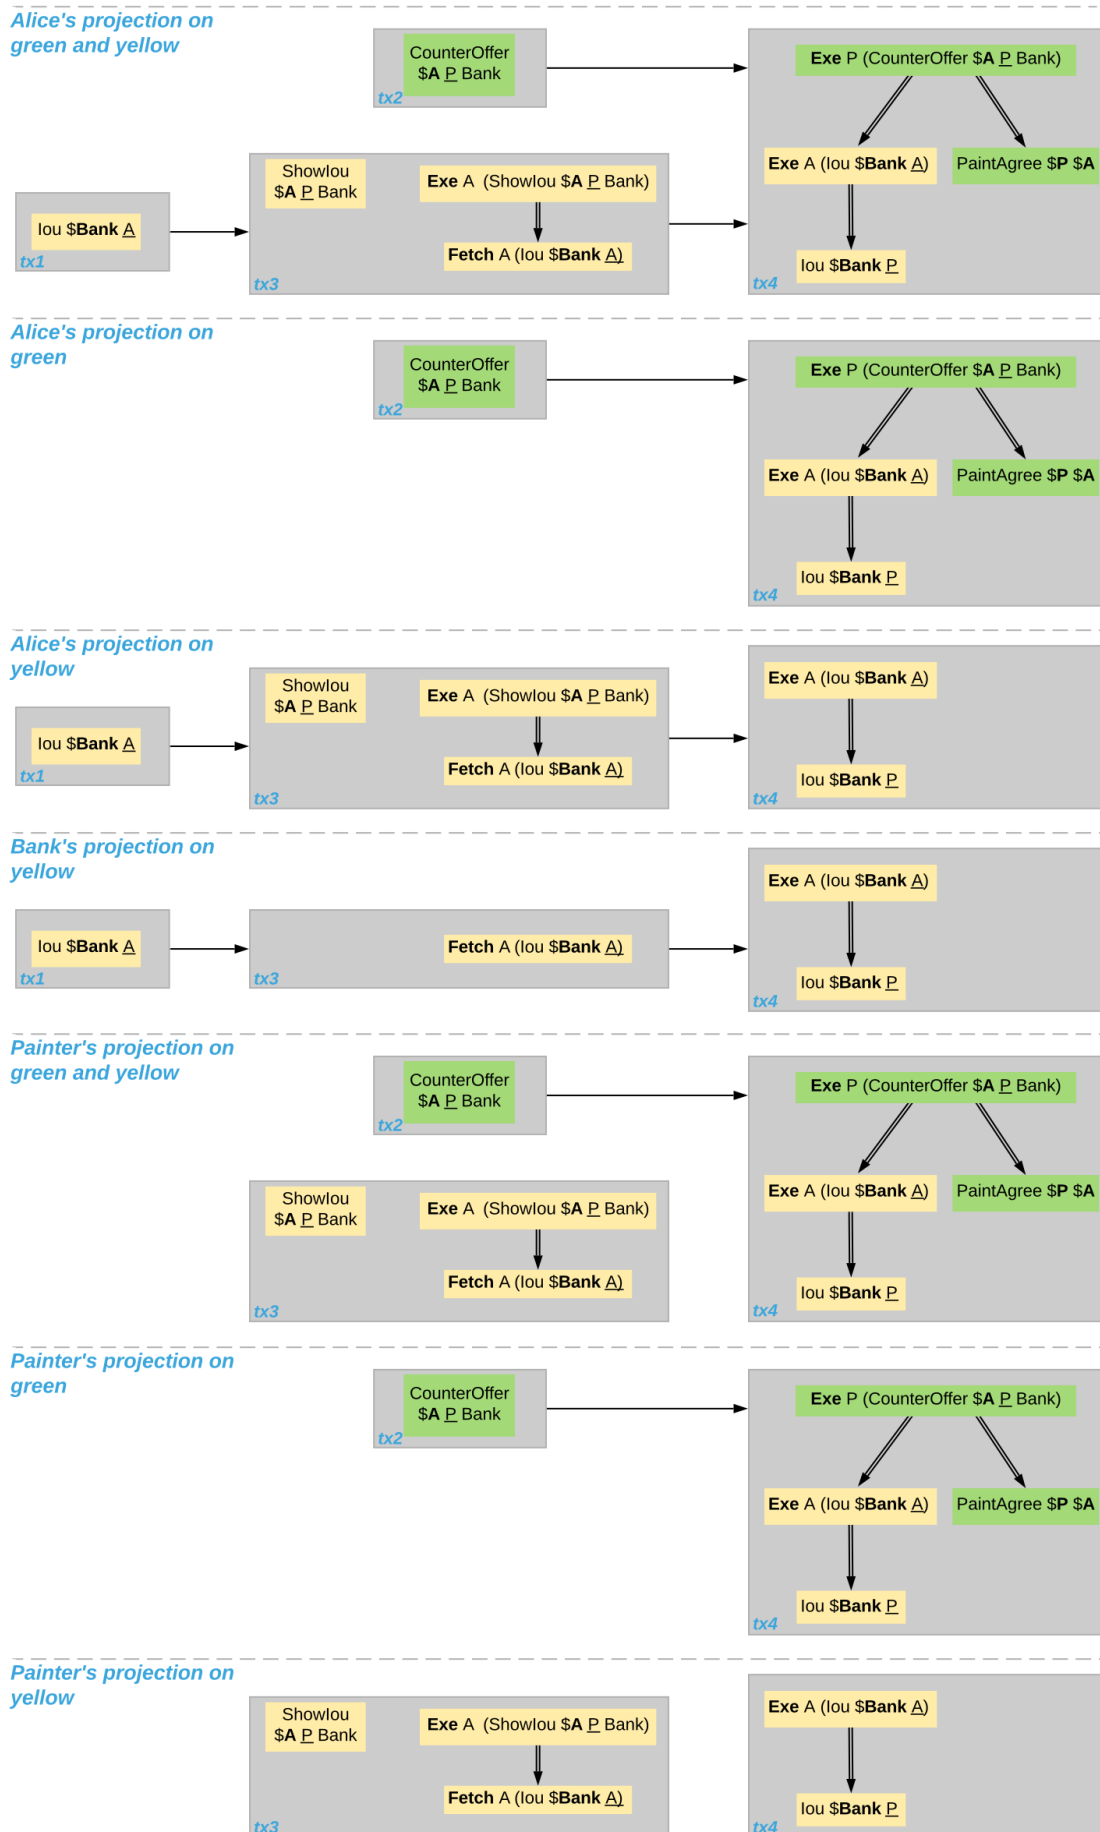

The notions of X -minimality and X -reduction extend to a party P on a set Y of ledgers accordingly.

Definition Ledger-aware projection for multi-ledger causality graphs Let G be a multi-ledger consistent causality graph and Y be a set of Daml ledgers. The **projection** of G to party P on Y (P -**projection** on Y) is the P -reduction on Y of the following causality graph G' , which is P -consistent on Y :

The vertices of G' are the vertices of G projected to P on Y , excluding empty projections. There is an edge between two vertices v_1 and v_2 in G' if there is an edge from the G -vertex corresponding to v_1 to the G -vertex corresponding to v_2 .

If G is a multi-ledger consistent causality graph, then the P -projection on Y is P -consistent on Y , too.

For example, the [multi-ledger causality graph for the split paint counteroffer workflow](#) is projected as follows:

The following points are worth highlighting:

In Alice's projection on the green ledger, Alice witnesses the archival of her *lou*. As explained in the [Ledger API Ordering Guarantees](#) below, the **Exercise** action is marked as merely being witnessed in the transaction stream of a Participant Node that hosts Alice on the green ledger but not on the yellow ledger. Similarly, the Painter merely witnesses the **Create** of his *lou* in the Painter's projection on the green ledger.

In the Painter's projections, the *Showlou* transaction tx3 is unordered w.r.t. to the *CounterOffer* acceptance in tx4 like in the [case of ordinary causality graphs](#). The edge tx3 -> tx4 is removed by the reduction step during projection.

The projection of transfer actions can be illustrated with the [Multi-Ledger causality graph with transfer actions](#). The A-projections on the yellow and green ledger look as follows. The white color indicates that a transfer action has no incoming or outgoing ledger annotation. That is, a **Leave** action is white on the right hand side and an **Enter** action is white on the left hand side.

A's projection on green

A's projection on yellow

48.4 Ledger API Ordering Guarantees

The Transaction Service and the Active Contract Service are derived from the local ledger that the Participant Node maintains for the party. Let Y be the set of ledgers on which the Participant Node hosts a party. The transaction tree stream outputs a topological sort of the party's local ledger on Y , with the following modifications:

1. **Transfer** actions with either an incoming or an outgoing ledger annotation are output as **Enter** and **Leave** events. **Transfer** actions with both incoming and outgoing ledger annotations are omitted.
2. The incoming and outgoing ledger annotations are not output. Transaction actions with an incoming or outgoing ledger annotation that is not in Y are marked as merely being witnessed if the party is an informee of the action.
3. **Fetch** nodes and **NoSuchKey** are omitted.

The flat transaction stream contains precisely the `CreatedEvents`, `ArchivedEvents`, and the **Enter** and **Leave** actions that correspond to **Create**, consuming **Exercise**, **Enter** and **Leave** actions in transaction trees on the transaction tree stream where the party is a stakeholder of the affected contract and that are not marked as merely being witnessed.

Similarly, the active contract service provides the set of contracts that are active at the returned offset according to the flat transaction stream. That is, the contract state changes of all events from the transaction event stream are taken into account in the provided set of contracts.

The [ordering guarantees](#) for single Daml ledgers extend accordingly. In particular, interoperability ensures that all local ledgers are projections of a virtual shared multi-ledger causality graph that connects to the Daml Ledger Model as described above. The ledger validity guarantees therefore extend via the local ledgers to the Ledger API.

Chapter 49

Non-repudiation

The non-repudiation middleware, API and client library are only available in [Daml Enterprise](#) and are currently an [Early Access Feature in Alpha status](#).

When you are issuing a command over the Ledger API, there is an implicit trust assumption between the issuer of the command and the operator of the participant that the latter will not issue commands on behalf of the former.

The non-repudiation middleware and its client library are a Daml Enterprise exclusive feature that allows ledger operators to run participant nodes that will require each command to come with a verifiable cryptographic signature, which will be persisted by the operator. As the sole owner of the private key used to sign the command, the authenticity of the command is thus verified and preserved, ensuring that an operator cannot issue a command on behalf of the user and that the user cannot repudiate the command.

Note that this is an early access feature: its status is currently under development and further feedback can change how certain details might work once the feature is declared a stable part of Daml Enterprise. If you are interested in this feature, you are welcome to use it and give us feedback that will shape how this feature will ultimately come to be.

49.1 Architecture

The non-repudiation system consists of three components:

- the non-repudiation middleware is a reverse proxy that sits in front of the Ledger API that verifies command signatures and forwards the signed command to the actual participant node
- the non-repudiation API is a web server used by the operator to upload new certificates and verify repudiation claims
- the non-repudiation client is a gRPC interceptor that can be used alongside any gRPC client on the JVM, including the official Java bindings, that will ensure that commands are signed with a given private key

49.2 Run the Server-side Components

The server-side components are the middleware and the API. Both can be run as a single process by running the non-repudiation fat JAR provided as part of Daml Enterprise.

Note that at the current stage you need to also have a PostgreSQL server running where signed commands will be persisted.

The following example shows how to run the non-repudiation server components by connecting to a participant at localhost:6865 and proxying it to the 6866 port, using the given PostgreSQL instance to persist signed commands and certificates.

```
java -jar /path/to/the/non-repudiation.jar --ledger-host localhost --ledger-port 6865 --proxy-port 6866 --jdbc url=jdbc:postgresql:nr,user=nr,password=nr
```

For details on how to run them, please run the fat JAR with the `--help` command line option.

49.3 Use the Client

The client is a gRPC interceptor which is available to Daml Enterprise users (hence, it's not available on Maven Central).

The Maven coordinates for the library are `com.daml:non-repudiation-client`.

The following example shows how to use this interceptor with the official Java bindings

```
PrivateKey key = readYourPrivateKey();
X509Certificate certificate = readYourX509Certificate();
NettyChannelBuilder builder = NettyChannelBuilder.forAddress(hostname, port);
builder.intercept(SigningInterceptor.signCommands(key, certificate));
DamlLedgerClient client = DamlLedgerClient.newBuilder(builder).build();
client.connect();
```

49.4 Non-repudiation Over the HTTP JSON API

The non-repudiation middleware acts *exclusively* as a reverse proxy in front of the Ledger API server: if you want to use the HTTP JSON API you will need to run your own HTTP JSON API server and start it with a certificate that will be used to sign every command issued by the HTTP JSON API to the participant.

The HTTP JSON API bundled with Daml Enterprise has the following extra command line options that *must* be used to run an HTTP JSON API server against the non-repudiation middleware:

- `-non-repudiation-certificate-path`: the path to the X.509 certificate containing the public counterpart to the private key that will be used to sign the commands
- `-non-repudiation-private-key-path`: the path to the file containing the private key that will be used to sign the commands
- `-non-repudiation-private-key-algorithm`: the name of the cryptographic algorithm of the private key (for a list of names supported in the OpenJDK: <https://docs.oracle.com/javase/8/docs/technotes/guides/security/StandardNames.html#KeyFactory>)

49.5 TLS Support

At the current stage the non-repudiation feature does not support running against secure Ledger API servers. This will be added as part of stabilizing this feature.
